LEWIS, MERIWETHER (1774-1809), American explorer, was born near Charlottesville, Virginia, August 18, 1774. In 1794 he volunteered with the troops called out to suppress the "whisky insurrection," was commissioned as ensign in the regular army in 1795, and as captain in 1800, and was President Jefferson's private secretary from 1801 to 1803. On Jefferson's recommendation he was appointed by Congress to conduct, in connexion with Captain William Clarke, an expedition to the headwaters of the Missouri river, and thence across the mountains to the Pacific Ocean—the first extended exploration of the north-western portion of the United States. The States had as yet acquired no claim to this region, and the exploration was designed by Jefferson in the interests not only of geographical science but of territorial acquisition. Lewis and Clarke, setting out late in 1803 with twenty-eight men, spent the winter at the mouth of the Missouri. Early in the spring the party embarked in several boats, and during the summer made the difficult ascent of the Missouri as far as 47° 21' N. lat., where the second winter was passed among the Mandan Indians. In 1805 the ascent of the Missouri was continued as far as the tributary which they named Jefferson river, which was followed to its source in the south-western part of what is now Montana territory. Procuring a guide and horses from the Shoshone Indians, they pushed westward through the mountains, and on October 7 embarked in canoes on a tributary of the Columbia river, the mouth of which they reached on November 15. They had travelled upwards of 4000 miles from their starting point, had encountered various Indian tribes never before seen by whites, had made scientific collections and observations, and were the first explorers to reach the Pacific by crossing the continent north of Mexico. After spending the winter upon the Columbia, they made the return journey across the mountains and down the Missouri, reaching the Mississippi in September 1806. The reports of the Lewis and Clarke expedition attracted great attention at the time, and it has scarcely been exceeded in romantic interest by later explorations in any quarter of the globe. The leaders and men of the exploring party were rewarded with liberal grants of land, and Lewis was made governor of the territory of Missouri. In the untroubled quiet of his new duties his mind, always subject to melancholy, became unbalanced, and, while on his way to Washington, he committed suicide near Nashville, Tennessee, October 11, 1809.

Jefferson wrote a memoir of Lewis, published in 1814 in connexion with Biddle and Allen's *Narrative of the Lewis and Clarke Expedition*. A new edition by M'Viekar was published at New York in 1843.

LEWISTON, a city of the United States, in Androscoggin county, Maine, is situated 36 miles north of Portland, on the left bank of the Androscoggin, and is connected by several bridges with Auburn, a city of 9556 inhabitants, and the capital of the county. As the river at this point breaks over a ledge of mica schist and gneiss, and the natural fall of 40 feet has been raised to 50 feet by a strong granite dam, Lewiston commands an abundant supply of water-power. Cotton and woollen goods (shirtings, sheetings, cassimeres, beavers, tweeds, cloakings), twine, boots and shoes, machinery, &c., are produced to the annual value of \$11,000,000—there being nine considerable manufacturing corporations in the city besides the Franklin Company, which owns the entire water-power. The city hall (1872) is a very fine building; and a public library (over 6000 volumes in 1880) was founded by the corporation in 1861. Bates College, founded by the Free Baptists in 1863-64, and named in honour of Benjamin F. Bates of Boston, possessed in 1880 11 professors, 161 students, and a library of 5537 volumes.

Lewiston dates from 1770. In 1795 it was incorporated as a town, and in 1861 as a city. The population was 3584 in 1860, 7424 in 1860, 13,600 in 1870, and 19,083 in 1880.

LEXINGTON, capital of Fayette county, Kentucky, is situated near the centre of the State, in the midst of a table land 1100 feet above the sea, known as the Blue Grass region. It stands on a small tributary of the Kentucky river, 79 miles south of Cincinnati, and 94 miles east by south of Louisville. The population (3584 in 1850, 7424 in 1860, and 13,600 in 1874) in 1880 was 16,656, including about 8000 negroes. Lexington is an important railway junction, has an extensive trade, and manufactures whisky, flour, bagging, ropes, carriages, and machinery. Two railroads, completed in 1882, give access to the mountainous eastern region of the State, from which iron, coal, and timber are obtained in abundance. The surrounding district is characterized at once by beauty and fertility, and the town has been laid out in a spacious and attractive style. It is the seat of the State university (chartered in 1858, originally opened at Harrodsburg in 1859, and removed to Lexington and incorporated with the Transylvania university in 1865), the State agricultural college, and one of the State lunatic asylums (625 patients). Besides the university library, there is a public library of 15,000 volumes.

Lexington was founded by Colonel Robert Patterson in 1775, and received its name in honour of the first contest in the war of American independence, fought in April of that year at Lexington, Middlesex county, Massachusetts.

Lexington in Kentucky must not be confounded with (1) Lexington, the capital of Lafayette county, Missouri, with a population in 1880 of 3996; or (2) Lexington, capital of Rockbridge county, Virginia, a place of 2771 inhabitants, and the seat of the Washington and Lee university (founded in 1749; professors in 1880, 9; students, 300; library, 15,000 volumes), and of the Virginia military institute, founded in 1839, under the patronage of the State, with 12 professors and 300 students.

LEYDEN, or LEIDEN, a city of the Netherlands, in the province of South Holland, about 20 miles south-west of Amsterdam, and 6 miles inland from the German Ocean. The Old Rhine, on which it is situated, enters at the eastern side by two arms which unite near the middle of the town so as to divide the western half into two nearly equal portions. Though the boundaries, which now include about 467 acres, have been six times extended, the general shape is wonderfully regular, nor is regularity wanting in the interior arrangement of the quiet respectable town with its canals and moats, its broad streets, and lifeless squares. The pensive and even melancholy impression which seems sometimes to produce on the stranger is easily explained. Leyden is *par excellence* an academic city; the bustle of its great markets for cattle and dairy produce

confined to certain spots, and lasts only for so many hours on so many days, and its industrial activity, considerable though it be, is not sufficient to give that appearance of life and movement which their flourishing local and transit trade makes so generally characteristic of the towns of Holland. The woollen goods (coverlets and broadcloths), the cotton stuffs, the worsted and yarns, the iron and copper wares, and the books and lithographic work which it still produces, are far from maintaining for it the position which it enjoyed when, at the close of the 15th century, its weaving establishments (mainly broadcloth) numbered from three to four hundred; or when, after the expulsion of the Spaniards, Leyden cloth, Leyden baize, and Leyden camlet became familiar terms at home and abroad. Owing to changes of fashion, unwise preservation of old customs and institutions, party spirit, the development of manufactures in other places, these industries had so far declined in the beginning of the 19th century—the total production of all the factories in 1802, for example, did not exceed 1086 pieces of cloth—that the baize manufacture was altogether given up, and the beautiful Say (Worsted) Hall was closed. Although after the revolution of 1813 comparative prosperity was the result of the removal of the French yoke, and more especially of the

Plan of Leyden.

introduction of steam, the times of a Maurice or a Frederick Henry have never returned, and still less the wonderful days of the 15th century. The university is still a flourishing institution, with fifty professors; but other universities have grown up in the Netherlands, and even professors of European reputation can no longer attract from foreign lands the numbers that visited Leyden in the days of Lipsius, Vossius, Heinsius, Gronovius, Hemsterhuis, Ruhnken, Valckenaeer, Scaliger, and Boerhaave. As a class the students are remarkably quiet and orderly. Many are destined to a diplomatic career. The university (*Akademie*) was opened in February 1575, and originally located in the convent of St Barbara. In 1581 it was transferred to the convent of the White Nuns, the site of which it still occupies, though the building was destroyed in 1616. Of the institutions connected with the university it is sufficient to mention the library (upwards of 160,000 volumes and 4650 MSS. and 2100 pamphlet portfolios), rich in Oriental and Greek manuscripts and old Dutch travels; the botanic gardens, with splendid collections of East Indian plants; the observatory (1860); the museum of natural history, one of the principal establishments of its kind in Europe; the museum of antiquities, with a specially valuable Egyptian department; the ethnographical museum, of which the nucleus was Von Siebold's Japanese collections; and the national insti-

tution for East Indian languages, ethnography, and geography. The Thysian library and the library of the Society of Dutch literature (1766) are both large collections, the former especially rich in legal works and native chronicles; the great school of navigation, and the Remonstrant seminary, transferred from Amsterdam in 1873, deserve special mention, and in general it may be said that there is no city in the Netherlands better supplied than Leyden is with educational and intellectual institutions.

Objects of artistic and antiquarian interest are fewer than might be expected from the position which Leyden holds in the history of painting (Rembrandt, Jan Steen, and Gerard Douw were natives of the town); but such as they are—pieces by Van Finck, Fr. van Mieris, Cornelis Engelbrechtszoon, Lucas of Leyden, and other masters

they have for the most part been collected in the newly founded municipal museum located in the old cloth hall. More interesting is the great collection of portraits of famous professors in the aula of the university. All the gate-houses of the city were still standing about the close of the 17th century: two only, the Zijlpoort and the Morschpoort have been spared. The old town-hall is a quaint 16th century building, and St Pancratius church has some striking features. Near the site of the Rijnsburg gate is the statue of Boerhaave by Stracké. The "Burg," on an artificial mound (perhaps of Roman origin) in the centre of the town, is an old circular wall resting on twenty arches; it forms a favourite promenade, and affords a fine point of view. Towards the south side of the town lies an open space, suggestively called the Ruin, which in 1807 was the scene of a terrible disaster, a powder-ship blowing up and destroying eight hundred houses and killing hundreds of men. In 1623 the population of Leyden was much more than 50,000, and in 1610, it is estimated, reached 100,000. Between 1796 and 1811 it sunk to 30,000. In 1850 it was 35,864; in 1870, 38,943 (9632 Roman Catholics, 396 Jews) in 182 about 41,000.

Though *Lugdunum Batavorum* is used as the Latin name for Leyden, there is no positive connection of the town itself with the *Lugdunum* of the Roman Empire. It first appears in 11th and 12th century documents as *Lex* (Latin), *Leithan*, and *Leithan*. The history of Leyden tells the same general line as the history of the Netherlands. During the period of the counts the city suffered from the quarrels of a count with another (as when Countess Ada was besieged in the castle of Loen in 1203), or of the nobles with the counts (1119 and 1485) it was besieged and captured by the French (1568) and by the "Hooks" (1572). From Floris V, it received the confirmation of its privileges (1266) and of its freedom from all the *houthout* Holland (1299). During the struggle with the *houthout* it overthrew itself with glory by the persistence with which it fought against the double *houthout* of a 31st October 1573 and 21st March 1574, and from 25th May to 2d October 1574. *Revolte of the Dutch Republic*, vol. ii. With the internal troubles of the 17th century it was closely connected. Godefrid, one of the first professors of its university, gave rise about 1578 to a question of heresy which formed in some of the public to the great contest in which his successors Armini and Gomarus were protagonists. In 1587 Leicester vainly attempted to bring the city over to his side; in 1618 Maurice was then restrained to alter the government; and in 1672 there were violent disturbances in connexion with the elevation of William III. to the stadtholdership. The revolution, excited by the French, took place in 1798; and in 1813 the Rhinish peasants, in revolt against the conscription, marched into the city. In 1836 there was a great inundation caused by the Haarlem Lake. The bicentenary of the university was celebrated with great ceremony in 1874.

See *Micus, Beschrijving der Stad Leyden*, 1772, 84.

LEYDEN, JOHN (1775-1811), was born on the 8th September 1775, at Denholm on the Teviot, not far from Hawick. Like most Scottish villages, Denholm is commonplace and uninteresting, but Leyden's upbringing was in a wilder part of the country, at the foot of Kuberlaw, whither his father had gone as shepherd to the relation of

the family. Though he did not attend school till he was nine years old, long before that he had learnt at home to read, and had devoured all the books he could lay his hands on in the border farm houses and cottages. Naturally his parents thought that a boy so fond of letters was meant for something else than shepherding; and, as the only scholarly office clearly within their horizon was that of a parish minister, they concluded that his gifts pointed in that direction, and with much stinting of their own little comforts sent him to Edinburgh university in 1790. There the uncouth lad, dressed in rough homespun, with a voice that smacked strongly of the Jed and the Teviot, played his part manfully enough in the class-work, but still better in the "societies" where Brougham, Jeffrey, Sydney Smith, Horner, and other clever young fellows were then chopping logic and cracking jokes. Leyden was a diligent but somewhat miscellaneous student, reading everything apparently, except theology, for which he seems to have had no taste. Accordingly, though he completed his divinity course, and took licence from the presbytery of St Andrews, and preached occasionally, it soon became clear that the pulpit was not his vocation, and that the border shepherds were not to find a second Thomas Boston in John Leyden.

In 1794 Leyden had formed the acquaintance of Dr Robert Anderson, editor of *The British Poets*, and of *The Literary Magazine*, a cultivated but not otherwise remarkable individual, who, however, filled a rather important niche in the Edinburgh of that time. Contributions to his magazine were probably what brought them first together, but more important results followed from their intimacy than either the verses on "Rubenslaw," or "The Descent of Odin," translated from the Norse. For it was Anderson who introduced him to Dr Alexander Murray, and Murray, probably, who led him to the study of Eastern languages, to which that great scholar was so passionately devoted. Soon they became warm friends and generous rivals, though Leyden excelled, perhaps, in the rapid acquisition of new tongues, and acquaintance with their literature, while Murray was the more scientific philologist. Through Anderson also he came to know Richard Heber, by whom he was brought under the notice of Walter Scott, when he was collecting materials for his *Minstrelsy of the Scottish Border*. Leyden was admirably fitted for helping in this kind of work. A borderer himself, an enthusiastic lover of old ballads and folk-lore, he spared no pains to enrich the work that promised to bring fame to his beloved hills and gleus. Scott tells us how, on one occasion, Leyden walked 40 miles to get the last two verses of a ballad, and returned at midnight, singing it all the way with his loud, harsh voice, to the wonder and consternation of the poet and his household. Neither Scott nor Leyden, however, studied this folk-lore for proper scientific purposes. They cared only for the picturesque and the poetic in it, and were not very successful in their efforts to restore it to life. Of course, the rough old ballads themselves were a welcome addition to our literature, but Leyden's attempt to make Lord Soulis interesting in a modern ballad was something of a failure, and, though he might have made a Scotch Lorelei out of the mermaid of Corrievreckan, his poem wants the delicate touch of the German, and he does not know where to stop. Scott, however, got valuable assistance from him in his task, and learned to esteem highly the blunt integrity of the man, his literary enthusiasm, and his large attainments.

Leyden was evidently drifting away from the church into the life of a scholar, but as yet he had not found his line there; was indeed only wasting himself on miscellaneous learning. He had compiled a work of four hundred pages on the *Discoveries and Settlements of Europeans in Northern*

*and Western Africa*, suggested by Mungo Park's travels. He had edited for Constable *The Complaint of Scotland*, giving a glossary, and a long preliminary dissertation. He had printed various poems, and nearly finished his *Scenes of Infancy*, a poem in four books, based, no doubt, on border scenes and traditions, but meandering "at its own sweet will" over all the world, and a good way beyond it. There are, here and there, some effective enough lines in this poem, but, in the main, it is of the thin, artificial, big-sounding order, and has no unity of design, so that there is no particular reason why it should not go on for ever. He had also made some translations from Eastern poetry, Persian and Arabic, but they have not somehow the aroma of the East. Clearly, here was a man of great and varied powers which, however, were like to run to waste unless he found a definite field to work in. So, at last, friends got him an appointment in India, at first on the medical staff, for which he qualified by a year of intense hard work; but it was hoped something more fitting would turn up by and by. In 1803, therefore, he sailed for Madras, and took his place in the general hospital there. From that he was soon promoted to be naturalist to the commissioners going to survey Mysore. Ere long, however, his knowledge of the languages and dialects of India procured him an appointment as professor of Hindustani, which he soon after resigned for a judgeship, and that again to be a commissioner in the court of requests, which required a familiarity with several Eastern tongues. Friends who had come from the same border country—Lord Minto, Sir John Malcolm, and others—had done what they could to make his path smooth for him, and his linguistic attainments had been recognized by Colebrooke, the greatest Oriental scholar of the day. But in 1811, having joined Lord Minto in the expedition to Java, on landing there he made his way into a library which was said to contain many Eastern MSS., without having the place aired, and was seized with shivering and sickness, first symptoms of the Batavian fever. The climate of India had never agreed with him, and his constitution had already been shaken by several serious illnesses. He was ill fitted, therefore, to endure the assault of this deadly complaint, and after three days of struggle he died on the 28th of August, in the thirty-sixth year of his age. Cut off thus prematurely, he has left comparatively little fruit of all the bright promise of his youth. As a poet he cannot take high rank, but in his knowledge of Eastern languages he would probably have been no mean rival of Henry Colebrooke, had he been spared a little longer to methodize and perfect his attainments. A genuine and generous nature, with a fine enthusiasm for learning, there were few of Britain's sons in India from whom friends at home looked for better work, and few therefore who were more deeply regretted. (w. c. s.)\*

LEYDEN, LUCAS VAN. See LUCAS.

LHASA, often written LASSA, for many centuries the chief city of Tibet. Though the place is of great celebrity, the accounts of it are scanty, and information has to be sifted from authorities differing considerably in age. Till recently the latitude even of Lhasa has been stated with variations extending over  $1\frac{1}{2}$  degrees, whilst the longitude has naturally been still more uncertain. The Jesuit Grueber, who was at Lhasa in 1661–62, made the latitude  $29^{\circ} 6'$ . In the maps of Tibet sent from China by the Jesuits, and engraved on five separate sheets in Du Halde, it is about  $29^{\circ} 40'$ . D'Anville, in his *Carte Générale du Tibet*, chiefly based on these last, but modified to suit other data, reverted nearly to Grueber's figure; Giorgi in his *A'-kabetum Tibetum* states it at about  $30^{\circ} 30'$ . Klaproth, stretching every datum to cracking point, to suit his fantasies about the course of the great river of Tibet, made it  $30^{\circ} 45'$  lat. (and  $91^{\circ} 50'$  long.); our last and

highest authority, Pundit Nain Singh, gives (from a mean of twenty observations)  $29^{\circ} 39' 17''$ , a result which closely confirms the Jesuit record. The longitude according to the protraction of the same explorer's route is  $90^{\circ} 57' 13''$ .<sup>1</sup> The height above the sea, by repeated observation of the boiling point, is stated at 11,700 feet (but the report of Nain Singh, on his second visit, gives 11,910). The city stands near the middle of a tolerably level plain, which is surrounded on all sides by hills, and extends about 13 miles from east to west and about 7 miles from north to south. It lies half a mile to the north of a considerable river called the Kichu Tsanpu, or Tsang-chu, flowing here from east-north-east (called by the Mongols, according to Klaproth, *Galjuo-Muren*, or "Turbulent River"), and joining the great Tsanpu (or upper course of the Brahmaputra) some 35 miles to the south-west.

The hills round the city are absolutely barren, and without growth of any kind except an occasional bush of so-called "Tartar furze." There are, however, gardens scattered over the plain round the city, and these are planted with trees of some size (it would seem cedar, willow, and cypress). Four defiles in the encompassing hills, by which the approaches to the city pass, are defended by as many forts. We may quote the description of Huc, which, though a little vague, is vivid, and is the only passage affording anything like a picture of this city, so difficult of access:—

"The sun was about to set as we completed our descent of the innumerable zigzags of the mountain path. Issuing into a wide valley, we beheld on our right Lhasa, the famous metropolis of the Buddhist world. The multitude of aged trees which encircle the city as with a girdle of foliage, the lofty white houses, terminating in flat roofs surrounded by terraces, the numerous temples with their gilt canopies, the Buddhala [*Palata*], crowned by the palace of the Dalai Lama,—all unite to give Lhasa a majestic and imposing appearance."

The meaning of the name *Lha Sa* is "God's ground." Formerly it used to be known to the Mongols as *Barontala*, the "right side" or western region; now, according to Huc they call it *Monke Dhot* or *Dehot*, "Eternal Sanctuary."<sup>2</sup> In eastern Turkestan it seems to be best known as *Jo*, a name which properly refers to the great central temple of which we shall speak.

The city is nearly circular in form, and according to Nain Singh less than a mile in diameter. It was walled in the latter part of the 17th century, but the walls were destroyed during the Chinese occupation in 1722. The population has been estimated at 40,000 to 80,000; the last estimate perhaps including the great population of monks and students in the convents near the city.<sup>3</sup>

The chief streets of the city are wide and straight, and in dry weather tolerably clean, but the inferior quarters are unspeakably filthy, and are rife with evil smells and large mangy dogs.<sup>4</sup> Part (much the greater part, according to Nain Singh) of the houses are of clay and sun-dried brick, but those of the richer people of stone and brick. All, however, are frequently white-washed, the doors and windows being framed in bands of red and yellow. In the suburbs there are houses entirely built of the horns of sheep and oxen set in clay mortar. This construction, according to Huc, is very solid and highly picturesque.

<sup>1</sup> This is corrected to the latest value of Madras longitude, viz.,  $80^{\circ} 14' 51''$ .

<sup>2</sup> The first word of this phrase is certainly the Mongol *munke*, "eternal." The second is probably a clerical error for *dehot*, which may represent the *Jo* of the next sentence, which is literally (Tib.) "master, lord," and is applied to very sacred images.

<sup>3</sup> Nain Singh says that a census in 1854 gave "9000 women and 6000 men, exclusive of the military and the priests." But these words are subject to too many doubts for precise interpretation.

<sup>4</sup> The Chinese have a proverb as to the three products of Lhasa being dogs, drabs, and lamas.

The houses generally are large, and of three stories at least. The owner of the house, with his family, occupies the upper story, whilst the two lower floors swarm with tenants. Externally the lower part of Tibetan houses generally presents lofty dead walls pierced by a few air-holes only; above these rise tiers of windows with projecting balconies, and over all flat broad-eaved roofs at varying levels. According to Desideri, in the better houses there are often spacious and well-finished apartments, the principal halls, the verandas, and terraces being often paved with a composition of coloured fragments of stone set in a cement of resin, &c., which with much beating and rubbing becomes like a surface of polished porphyry. In every house there is a kind of chapel or shrine, carved and gilt, on which are set images and sacred books, and before them lamps and incense, with the usual offerings of barley, fruits, &c.

Lhasa is not only the nucleus of a cluster of vast monastic establishments, which attract students and aspirants to the (so-called) religious life from all parts of Tibet and Mongolia, and the seat of a quasi papacy, but is also a great place of pilgrimage, so that the streets and public spaces swarm with visitors from every part of the Himalayan plateau, and from all the steppes of Asia between Manchuria and the Balkash Lake, who come to adore the living Buddha, to seek the purgation of their sins and the promise of a happy transmigration, and to carry away with them holy relics, blessed rosaries, and all the miscellaneous trumpery which is set forth to catch the money of idle people in Asia and Europe, whether they are pilgrims or frequenters of mineral waters; whilst as usual a great traffic arises quite apart from the pilgrimage. The city thus swarms with crowds attracted by devotion and the love of gain, and presents an astonishing diversity of language, costume, and physiognomy; though, in regard to the last point, varieties of the broad face and narrow eye greatly predominate. Much of the retail trade of the place is in the hands of the women. Huc's account of the curious practice of the Lhasa women in plastering their faces with a dark-coloured unguent is well known, but it does not rest on his authority alone.

During the month of December especially traders arrive from western China by way of Tatsienlu (Tachudo of the Tibetans), bringing every variety of silk stuffs, carpets, china-ware, and tea; from Siningfu (commonly in Tibet and Turkestan called *Siling*, Ziling, or Zling, a circumstance that has caused sundry misapprehensions) come silk, gold lace, Russian goods, carpets of a superior kind, semi-precious stones, horse furniture, horses, and a very large breed of fat tailed sheep; from eastern Tibet musk in large quantities, which eventually finds its way to Europe through Nepal; from Bhutan and Sikkim, rice; from the latter also tobacco; besides a variety of Indian and European goods from Nepal and Darjiling, and *charas* (resinous exudation of hemp) and saffron from Ladak and Kashmir. The merchants, who arrive in December, leave Lhasa in March, before the setting in of the rains renders the rivers impassable.

The tea importation from China is a large matter, on which an interesting paper has been written by Mr E. Baber. The tea is of the coarsest quality, derived from straggling and uncared-for trees, allowed to grow to a height of 10 feet or more, and the coarsest produce of these. This is pressed into bricks or cakes, and carried by porters. The quantity that pays duty at Tatsienlu is about 10,000,000 lb, besides some amount smuggled. ... doubt a large part of this comes to Lhasa. Tea is an

<sup>5</sup> Among articles sold in the Lhasa baz. bones, called by the people "lightning bone" and to have healing virtue.

absolute necessary to the Tibetan; he is miserable without it.

The chief industries of Lhasa are the weaving of a great variety of stuffs from the fine Tibetan wool; the making of earthenware (said to be of very good quality), and of the wooden porringers (varying immensely in elaboration and price) of which every Tibetan carries one about with him; also the making of certain fragrant sticks of pastille much valued in China and elsewhere.

It is curious that Tibet, though using coined money, seems never, strictly speaking, to have had a coinage of its own. Till nearly the end of last century the coinage had for a long time been derived from Nepal. That valley prior to the Gorkha domination (1768) was under three native dynasties (at Bhatgaon, Patan, and Khatmandu), and these struck silver mohurs, as they were called, of the nominal value of half a rupee. The coins were at first not struck specially for Tibetan use, but were so afterwards. These latter bore (obverse) a Nepalese emblem surrounded by eight fleurons containing the eight sacred Buddhist jewels, and (reverse) an eight-petalled flower surrounded by eight fleurons containing the names of the eight jewels in Tibetan characters. Ingots of Chinese silver were sent from Lhasa with a small proportion of gold dust, and an equal weight in mohurs was returned, leaving to the Nepal rajahs, between gold-dust and alloy, a good profit. The quality of these coins (weighing about 81 grains Troy) was low, and at last deteriorated so much that the Tibetans deserted the Nepal mints. The Gorkhas, after becoming masters of Nepal, were anxious to renew the profitable traffic in coin, and in this view sent a deputation to Lhasa, with a quantity of coin to be put in circulation. But the Gorkhas were mistrusted, and their coin refused. A coinage was then issued (it would appear once only) in Tibet for domestic use, modelled on an old Khatmandu pattern, and struck by Nepalese artists (see fig. 1). The Gorkhas, however,

FIG. 1.—Coin struck in Tibet, from specimen in India Library inscribed "27th year" (i.e., 1772 A.D.) from the principal residence of Galdan."

in 1788 and following years continued to strike coins of progressively debased quality, which were rude imitations of the old Nepalese mintage (see fig. 2), and to endeavour to force this currency on the Tibetans, eventually making the departure of the latter from old usage a pretext for war and invasion. This brought the intervention of the

FIG. 2.—Gorkha coin rubbing from in British Museum.

Chinese, who drove the Gorkhas out of Tibet (1792), and then began to strike silver coins for Lhasa use, bearing Chinese and Tibetan characters (see fig. 3). For practical use these Tibeto-Chinese coins (of which 2½ = 1

rupee, and which are known as *naktang*, i.e., *nagskyang*, "cash"), are cut into aliquot parts by the guidance of the figures on them. Large lumps of Chinese silver, stamped

FIG. 3.—Tibeto-Chinese coinage ("Kientung, 58th year," i.e., 1793 A.D.). From specimen in India Library.

with the imperial seal, are also used. But of late years there has been an enormous influx of Anglo-Indian rupees, so that these have become practically the currency of the country, even to the frontier of China, and are now counted, instead of being valued as bullion. They are called *Peiling ch'ranka*, or *chanka* (probably Hind. *tankai*), "English (Firinghi?) coins." Those that bear a crowned head of the queen are called *Lama* heads, the crown being taken for a wandering lama's head-gear. This great influx of rupees indicates a very considerable amount of trade with India. And, in spite of the extraordinary difficulties of the road eastward from Lhasa, quantities of trifling European articles find their way even to Tatsienlu on the Chinese frontier. Mr Baber found quarter-rupees very popular as buttons, British army buttons very common, corkscrews offered for sale (though no one knew their use), and tin-plates very common, stamped with the heads of Napoleon III., Mr Gladstone, and other celebrities.

The permanent population embraces, besides Tibetans of the country, settled families of Chinese and Kashmiris in considerable numbers, as well as people from Bhotan and Nepal, from Ladak and even from Patna. The Kashmiris and many of the other foreigners are Mohammedans, and much of the trade is in their hands. Desideri, a century and a half ago, speaks also of Armenians and even "Muscovites." The Chinese have a crowded burial-ground at Lhasa, tended carefully after their manner. The Kashmiris, who are called *Khach'hé*, are an important body, and have their mosque, and a provost, at once civil and religious, who is recognized by the Government. With their turbans, their fine Caucasian features, and their beards, they strikingly contrast with the mass of other nationalities. The Nepalese (called at Lhasa, according to Hue, *Pe-b'na*) supply all the mechanics and metal-workers. There are among them excellent gold and silversmiths; and they make the elaborate gilded canopies crowning the temples, which form so notable a feature of Lhasa. Hue describes a striking custom among the native population. Every evening, as light begins to fail, they leave off business, and form groups in the streets; all sit down and begin to chant prayer in a low voice. "The combination of religious music arising from these numerous companies produces an aggregate of vast and solemn harmony, which is exceedingly moving."

In the middle of the city is an open space or *place*, in which markets are held; this is densely thronged in the afternoon and evening. On the north side, overlooking this *place*, is a great building which is the residence of the *Gyalpo*, or so-called king of Tibet. It was built at great cost by the dissolute Lama who was set up by the crafty regent Sangje Gyampo, and put to death by the Calmuck prince Latsan or Jenghiz Khan in 1706-7 (see *infra*); and, as the Lama used to divert himself there with the dances of the ladies of Lhasa, the palace is known as the

*Trasi-khang* or "dancing house" (so Desideri; the word *trasi* cannot be identified).

Immediately west of the *place* stands the great temple and convent of Labrang (*bLa-brang*, "Lama-house"), regarded as the *umbilicus* and centre of all Tibet, and from which all the main roads are considered to radiate. This is not merely the great metropolitan convent, sanctuary, and church-centre of Tibet, the St Peter's or Lateran of Lamaism, but contains the palace of the government and seat of civil administration. It is believed to have been founded by the Tibetan Constantine, Srong-dsan-gampo, in the 7th century, as the shrine of one of those two very sacred Buddha images which were associated with his conversion, and with the foundation of the civilized monarchy in Tibet. From this image, called *Jo*, or *Jā*, it is known to the Mongols as the *Jo Erdeni* ("the precious Lord") or *Jo Shakyamuni* (to the Chinese as *Ta-shao-si*, "house of the great *Jā*"), and hence as *Ju* or *Jo* simply, a name used in eastern Turkestan (as already noticed) and probably in Mongolia, as a synonym of Lhasa. The temple appears to be known also as *Lhasa Chhod-khang*, "offering-house of Lhasa," and among Indian and Nepalese visitors as *Māchendra Nāth*.<sup>1</sup> The *Porāṇa* as a sacred centre is modern, whilst the Labrang attaches itself to the whole thread of Tibetan history and religion. On one of the walls of this temple is a picture of the famous "Master of the Law," Hwen T'sang, the travelling doctor of Buddhism (see vol. xii. p. 418), whose journeys have in the revolution of the ages become so familiar to European students, as a mine of information on the geography and history of India during a period so clouded as the 7th century. He is represented with three of his disciples. And before the gate of the Labrang stand several monuments of antiquity, especially that famous obelisk spoken of below, which bears the inscribed record of the treaty of peace concluded in 822 between Thi-de-srong-tsan, king of Tibet, and the emperor Mo-tsung of China. Before this obelisk the apostate from Lamaism, Langdharma, brother and successor of the last-named king, was standing in proud contemplation, when a fanatic recluse, who had been stirred by a vision to avenge his persecuted faith, shot him with an arrow in the forehead.

The main building of the Labrang is three stories high. The entrance, facing eastward, forms a portico supported on six great timber columns, richly carved and gilt, whilst the walls are painted with the history of Sakya. Great folding-doors, covered with reliefs in bronze and iron, lead to the ante-hall, and from thence a second gate to the *cella* (so to call it) of the temple. On each side of the gate, two and two, stand colossal of the spirit-kings of the four points of heaven. Within is a great basilica, divided into naves and aisles by many pillars, whilst along each wall, north and south, are chapels or sanctuaries, fourteen to a side.

At the west end steps ascend to a quadrangular choir or chancel, on each side of which also are three chapels, and at the extremity a rectangular apse (if it may be called so), and in it is the altar or graded throne, on which stands the great image of Sakya, seen through a lattice of silver gilt,—the higher shelves or offsets of the altar being beset with small figures in precious metals of *devotas* and saints, and the lower ones with lamps burning josticks, platters holding offerings of butter and meal, flowers modelled from butter, &c. In the choir to the right (*i.e.*, looking from the altar) is the elevated and stepped throne of the Grand Lama, laid with splendid cushions, succeeded by the nearly equal throne of the Teshu Lama of Shigatzé, and then by the seats of other ecclesiastical potentates, reborn and elected, in order; on the left of the Buddha throne, opposite the Grand Lama's, and of equal height, there is said now to be a throne for the emperor of China, then, at a lower level, that of the so-called king of Tibet, whilst the ministers of state follow opposite the inferior lamas.

In a space shut in with silver lattice, on the south side of the

chancel-steps, are seen fourteen or fifteen great disks of silver, set with precious stones, on which are embossed fundamental Buddhist symbols, such as their system of cosmogony, the circle of transmigration, the births of Sakya, &c.

The great nave or central aisle of the basilica is truly hypæthral, but on the second and third apparent floors it is encompassed with colonnades or verandas, from which the women and the laity look down upon the lamas engaged in chanting the services or in other functions. The sanctuary or chancel itself towers above the rest of the building, and is crowned with a rectangular canopy or pavilion of gilt metal, which rises to a ridge serrated with fantastic figures. This canopy rests on columns which are also gilt, and from its eaves and angles hang bells that tinkle with every breeze, whilst the pillars beneath the eaves are crowned with a great frieze of bas-relief, embossed in gilt metal.

This ancient temple contains a vast accumulation from the ages of gold and silver vessels, lamps, reliquaries, and precious bric-à-brac of every kind, which is annually exposed to view in the spring festivities. The daily offices in the Labrang are attended by crowds of monks, and which leads round it is constantly traversed by the people in the circuit as a work of merit, always in a particular direction.

Besides the convent-cells, halls of study, and magazines of precious metal, buildings grouped about the Labrang are occupied, as we have said, by the civil administration, *e.g.*, as treasuries, customs office, courts of justice, &c.; and there are also private apartments for the Grand Lama and other high functionaries. No woman is permitted to pass the night within the precinct.

Another great and famous temple is the *Ramo-chhé* ("large pen or fold"), at the north end of the city. This is also regarded as a foundation of Srong-dsan-gampo, and is said to contain the body of his Chinese wife, and the second of the primeval palkias, the image that she brought with her to the Snow Land; whence the Mongols and Chinese call it the temple of the little *Jā*. The lamas of this convent, as well as of that next to be mentioned, are noted for their pretensions to and practice of magical arts, one of the degrading characteristics of the lama forms of Buddhism. The orthodox "yellow" sect indeed profess to distinguish between lawful and unlawful magical formulae, and to give degrees only in the former. The lamas of Ramo-chhé have also the ill-repute of cultivating that species of doctrine which is connected, like their magic, with Tantric mysticism, and which professes to destroy sensual passion by the contemplation of its representations. The walls of the convent are defiled with a series of sculptures of gross obscenity.<sup>2</sup>

Another convent within the city is that of *Mora*, also near the north end, remarkable for its external order and cleanliness, and though famous like the last as a school of orthodox magic, noted also for the printing-house in the convent garden. Lastly we notice the *Garmakhi*, the inmates of which are sorcerers of the ruder kind, who seem really to represent the rude medicine-men of the superstitions which preceded Buddhism in Tibet. As the vulgar will not dispense with their marvels (knife-swallowing, fire-breathing, cutting off their own heads, and the like), every great orthodox monastery in Tibet keeps one of these conjurers, who does not belong to the fraternity of the house, but lives in a particular part of it, bearing the name of *Choi-dzong* (*Chhos-skyong*) or "protector of religion," and is allowed to marry. These practitioners of the black art possess no literature, but hand down their mysteries from father to son. Their fantastic equipment, their frantic bearing, and their cries and howls seem to identify them with the grossest Shamanist devil-dancers, strongly remote in externals from the gentle and cultivated persons in the higher ranks of the Lama Church, of whom we read in Turner or Hue. Other monasteries in or near the city are the *Chumling* at the north west corner; the *Tankoling*

<sup>1</sup> So in Nain Singh's narrative. But the word is properly *Machendranāth*, which is the name of a saint adored by the Nepalese Buddhists, and identified with Padmapani, the fourth Dhyāni Bodhisattva of their system. (see Hodgson in *Journ. Roy. As. Soc.* xviii. 394).

<sup>2</sup> It was in this convent that P. Desideri studied the religion of the lamas. "From March to July," he says, "I set myself I will not say to read, but rather to *decour* the chief books of the *Ka-shi phin*, and to take in a complete knowledge of all that pertains to that false religion."

at the west of the city; the *Kontyaling*, about a mile west of the city, at the foot of a low isolated hill called Chapochi. Three miles south, beyond the river, is the *Chochuling*. These four convents are known as "The Four Ling."

Leaving the city by the side of the Ramoch'hé, we see on our left the famous Potala with its many edifices crowning and seeming to grow out of a rocky hill, which rises like an island from the plain. It forms altogether a majestic mountain of building. At the south base of the rock is a large space inclosed by walls and gates, with great porticoes on the inner side. This swarms with lamas, its nooks with beggars basking in the sun. A series of tolerably easy staircases, broken by intervals of gentle ascent, leads to the summit of the rock. The whole width of this is occupied by the palace. The central part of this group of buildings rises in a vast quadrangular

mass, in four stories, to a great height, terminating in a gilt canopy similar, it would seem, to that on the Labrang. Here on the lofty terrace is the Grand Lama's hall of audience, and from this great height he looks down upon the crowds of his votaries far below, thronging the plain, and streaming to kneel before the sacred hill. The monastic buildings attached to the palace temple are said to contain cells for ten thousand monks. Other palatial buildings, towers, chapels, *chodtens* (chaityas), pavilions, gleaming with gold and silver, Buddhas and other idols, cluster round and crown the three peaks of Potala. The palace itself is said to be painted externally with red and white stripes. The walls and ceilings of all the chief apartments and temples are covered with rich silks. We give an engraving of it (fig. 4), extracted from a Chinese view of Lhasa, published by Klaproth in the work quoted

FIG. 4.—Potala, the Palace-Temple of the Grand Lama.

at the end. The Potala has every appearance of having been drawn from the reality. Two avenues bordered with trees of considerable size lead from the city to the foot of Potala. "You see there constantly," says Huc, "a great number of foreign pilgrims, passing between their fingers the beads of their long Buddhist rosaries, with lamas of the court splendidly attired, and mounted on richly caparisoned horses. There reigns in the neighbourhood of the Potala great and incessant movement; but for the most part everybody is grave and silent; religious thoughts appear to occupy the minds of all." It would seem that between the palace and the city runs a stream which is crossed by a bridge called "The Bridge of Glazed Tiles."

On the north side of the rock a wide and easy road descends winding. By this, which has a parapet along the edge, it is lawful to ride. Not far from the base is a garden palace in the middle of a lake which is surrounded by trees and shrubberies. This palace, called *Lukhang*, is described by Desideri as of attractive style, and circular in form, with a *loggia* or portico running all round, and adorned with paintings. Here the dissolute Lama who built it, at the end of the 17th century, used to give himself up to dissipation with the women of Lhasa. Several other villas or gardens of the Tibetan pope are mentioned; in one of them the Panch'hen-Rinpoche (or Teshu Lama) is received when he visits Lhasa, and the two living Buddhas drink tea together there. It is in the numerous gardens round the town that those large trees grow of which Huc

speaks as giving Lhasa such a green girdle of foliage. There is no natural wood.

No country in the world—not even Spain or Italy in the last century—has so abounded in convents and monks as Tibet. The district of Lhasa alone is said to contain thirty great convents, besides many smaller establishments, and a notice of Lhasa would be incomplete without some mention at least of the great monastic establishments which stand within a few miles of the city, and constitute an essential element in its existence. These are not single masses of building like the great convents of Europe. The temple (*Lha-khang*) is the focus of the whole. Round this are gathered numerous houses detached from one another, though not far apart, and generally three stories in height. In each of these are various apartments, each assigned to a monk of some authority and dignity, with several younger members or novices under his immediate direction. Each house has a little garden, and a quantity of vases in which plants are grown. Library, storehouse, hostel, occupy other buildings, and a varying multitude of the peculiar Buddhist objects of adoration which we know as *dagwas* or *chaityas*, as well as of masts with sacred flags and streamers. The whole is usually enclosed in a lofty and solid wall. These establishments have undoubtedly a vast population, though we can hardly accept specific figures, in which indeed authorities do not agree. Huc says the inmates of each of the three great convents which we are about to name amounted to

15,000; Nain Singh states them at 7700, 5500, and 3300 respectively; the former numbers seem excessive, the latter artificial; but no doubt the real numbers are large. In the Labrang they show a copper kettle holding more than one hundred buckets, which was used to make tea for the lamas who took part in the daily temple service.

The three great convents in the vicinity, all claiming to be foundations of Tsongkhapa, the mediæval reformer and organizer of the modern orthodox Lama Church, are the following:

1. *Bre-bung* (written *Bras-sPung*, "the Rice-Heap," so called from the shape of the hill on which it stands), called by Nain Singh *Debang*, is 5 or 6 miles from Lhasa, west of the city, at the entrance to the plain from the side of Shigatse and Nepal. In the middle of the convent buildings rises a kind of pavilion, brilliant with colour and gilding, which is reserved for the Dalai Lama, when he visits Brebung once a year, and expounds to the inmates. The place is greatly frequented by the Mongol students who come to Lhasa to graduate, and is known in the country as the Mongol convent.

2. *Sera* ("The Golden") is 2 or 3 miles from the city on the acclivity of the hills which border the valley on the north, and close to the road by which pilgrims enter from Mongolia. The hill is planted with holly and cypress, and from a distance the crowd of buildings and temples, rising in amphitheatre against a background of trees, forms a pleasing picture. In the recesses of the hill, high above the convent, are scattered cells of lamas adopting the solitary life. There are three great temples rising in many stories, the walls of which are entirely covered with gilding, whence the convent's name. In the chief of these temples is preserved the famous *Dorjé* of Buddha, i.e., the *Yagor* or Thunderbolt (of Indra properly), or Adamant, the symbol of the strong and indestructible, which the priest grasps and manipulates in various ways during prayer. From this *dorjé*, according to one etymology at least, comes the name of the Hindayan sanctuary *Dorjilong* at Darjeeling. The emblem is a bronze instrument, shaped much like a dumb-bell with pointed ends, and it is said by Koepen to have been one of the later lama borrowings from Sraivism. The original is carried solemnly in procession to Labrang during the New Year's festival. In Sera P. Desideri found shelter during the capture of the city by the Dzungar Khan in 1717, spoken of below.

The hill adjoining Sera is believed to be rich in silver ore, but it is not allowed to be worked. On the summit is a spring, and a holy place of the Lhasa Mohammedans, who resort thither. Near the convent there is said to be gold, which is worked by the monks. "Should they . . . discover a nugget of large size, it is immediately replaced in the earth, under the impression that the large nuggets . . . germinate in time, producing the small lumps which they are privileged to search for" (Nain Singh).

3. *Galdan*.—This great convent is 10 or 12 miles east of Lhasa, on the other side of the Kichu Tsangpo river. It is the oldest monastery of the "Yellow" sect, having been founded by Tsongkhapa, and having had him for its first superior. Here his body is said to be preserved with miraculous circumstances, and here are other relics of him, such as the impression of his hands and feet in hard butter.

*Samayé* (*bSam-yas*) is another famous convent intimately connected with Lhasa, but it lies some 36 miles south-east on the left bank of the great Tsangpo. It was founded by Padma Sambhava (*Ur-gyen* of the Tibetans), the apostle who came from Udayana in the 8th century as the great reviver of Buddhism, and was at the head of the old Red sect. It is visited by the Dalai Lama once a year. It is surrounded by a very high circular stone wall, 1½ miles in circumference, with gates facing the four points of the compass. On this wall Nain Singh, who was here on his last journey (1874), counted 1030 *chaityas* of brick. One very large temple (*Lha-khan*) occupies the centre, and round it are four smaller but still very large temples. Many of the idols are of pure gold, and the wealth is very great. The interiors of the temples are covered with beautiful writing in enormous Nagari characters, which the vulgar believe to be the writing of Sakya himself.

*Lhasa Festivities*.—The greatest of these is at the new year. This lasts fifteen days, and is a kind of lama carnival, in which masks and mummings, wherein the Tibetans take especial delight, play a great part. The celebration commences at midnight, with shouts and clangour of bells, gongs, chank-shells, drums, and all the noisy repertory of Tibetan music; whilst friends exchange early visits and administer coarse sweetmeats and buttered tea. On the 2d day the Dalai Lama gives a grand banquet, at which the Chinese and native authorities are present, whilst in the public spaces, and in front of the great convents, all sorts of shows and jugglers' performances go on. Next day a regular Tibetan exhibition takes place. A long cable, twisted of leather thongs, is stretched from

a high point in the battlements of Potala slanting down to the plain, where it is strongly moored. Two men slide from top to bottom of this huge hypothenuse, sometimes lying on the chest (which is protected by a breast-plate of strong leather), spreading their arms as if to swim, and descending with the rapidity of an arrow-flight. Occasionally fatal accidents occur in this performance, which is called "the dance of the gods"; but the survivors are rewarded by the court, and the Grand Lama himself is always a witness of it. This practice occurs more or less over the Himalayan plateau, and is known in the neighbourhood of the Ganges as *Barat*. It is employed as a kind of expiatory rite in cases of pestilence and the like. And exactly the same performance is described as having been exhibited in St Paul's Churchyard before King Edward VI., and again before Philip of Spain, as well as, about 1750, at Hertford and other places in England (see Strutt's *Sports*, &c., 2d ed., p. 198).

The most remarkable celebration of the new year's festivities is the great jubilee of the *Monlam* (*s.Mon-lam*, "prayer"), instituted by Tsongkhapa himself in 1409. Lamas from all parts of Tibet, but chiefly from the great convents in the neighbourhood, flock to Lhasa, and every road leading thither is thronged with troops of monks on foot or horseback, on yaks or donkeys, and carrying with them their breviaries and their cooking-pots. They descend like swarms of bees upon the city, and those who cannot find lodging bivouac in the streets and squares or pitch their little black tents in the plain. The festival lasts six days, during which there reigns a kind of saturnalia, and the town is abandoned to these crowds of monks. Unspeakable confusion and disorder reign, whilst gangs of lamas parade the streets, shouting, singing, and coming to blows. The object of this great disorderly gathering is, however, supposed to be devotional. Vast processions take place, with mystic offerings and lama-music, to the Labrang and Morn convents; the Grand Lama himself assists at the festival, and from an elevated throne beside the Labrang receives the offerings of the multitude, and bestows his benediction.

On the 15th of the first month multitudes of torches are kept ablaze, which lighten up the city to a great distance, whilst the interior of the Labrang is illuminated throughout the night by innumerable lanterns shedding light on coloured figures in bas-relief, framed in arabesque of animals, birds, and flowers, and representing the history of Buddha, and other subjects, all modelled in butter. The figures are executed on a large scale, and, as described by Hue, who witnessed the festival at Kunbum on the frontier of China, with extraordinary truth and skill. These singular works of art occupy some months in preparation, and on the morrow are thrown away. On other days horse races take place from Sera to Potala, and foot-races from Potala to the city. On the 27th of the month the holy *Dorjé* is carried in solemn procession from Sera to the Labrang, and to the presence of the Lama at Potala.

Of other great annual feasts, one, in the fourth month, is assigned to the conception of Sakya, but appears to connect itself with the old nature-feast of the entering of spring, and to be more or less identical with the *Holi* of India. A second, the consecration of the waters, in September-October, appears, on the confines of India, to be associated with the Dasehra.

On the 30th day of the second month there comes off a strange ceremony, akin to that of the scapegoat (which is not unknown in India). It is called the driving out of the demon. A man is hired to perform the part of demon (or victim rather), a part which sometimes ends fatally. He is fantastically dressed, his face mottled with white and black, and is then brought forth from the Labrang to en-

game in quasi-theological controversy with one who represents the Grand Lama. This ends in their throwing dice against each other (as it were for the weal or woe of Lhasa). If the demon were to win the omen would be appalling; so this is effectually barred by false dice. The victim is then marched outside the city, followed by the troops, and by the whole populace, hooting, shouting, and firing volleys after him. Once he is driven off, the people return, and he is carried off to the Samayé convent. Should he die shortly after, this is auspicious; if not, he is kept in ward at Samayé for a twelvemonth.

Nain Singh, whose habitual accuracy is attested by many facts, mentions a strange practice of comparatively recent origin, according to which the civil power in the city is put up to auction for the first twenty-three days of the new year. The purchaser, who must be a member of the Brebung monastery, and is termed the *Jalwa*, is a kind of lord of misrule, who exercises arbitrary authority during that time for his own benefit, levying taxes and capricious fines upon the citizens.

*Climate, &c.*—Pundit Nain Singh, who lived at Lhasa continuously from 26th January to 21st April (1866), made indoor observations of the thermometer from 9th to 23d February hourly, with the exception of eight hours of sleep (11 P.M. to 7 A.M.); and the extreme variation in the record is from 26° (February 2d, 11 A.M.) to 45°·75 (February 22d, 2 P.M.). He also mentions that the river (Kichu Tsangpo) which flows by Lhasa was frozen in December,—the great river (Brahmaputra) being open and passed by boats. Water kept in the warmest part of a house froze, and burst the vessels holding it. It is not easy to draw very precise conclusions from these facts, but they perhaps indicate a somewhat less severe winter than that of Ladak, where the true air temperature is reckoned by Captain H. Strachey to range between zero and 30 Fahr. In other respects the Pundit's account of the climate does not differ materially from those we possess of western Tibet. He says, besides, that strong and high winds are very prevalent, especially during March and April; but snow fell only twice in the three months of his stay, and not deeper than 3 inches. The fall on the surrounding hills was somewhat heavier, but apparently it did not lie, for in general hardly any snow was to be seen from the city. Should the snowfall in Lhasa ever exceed a foot, it is regarded as an evil omen. What little Desideri says is to like effect. The cold, he says, was never hurtful to health, and he had often spent the night (in winter apparently) under the open sky, without suffering. Lightning, which occurs only in connexion with the summer rains, is never known to strike houses or to kill.

It begins to be warm in May, and the sun's power rapidly grows most oppressive. There is a distinct rainy season at Shigatze (July to September), and this appears to extend to Lhasa, though the information is not very precise. Nain Singh was told that earthquakes are unknown in the Lhasa province. Cholera is said to be unknown; but dysentery is often violent, and rapidly fatal. Cough and chest diseases are not prevalent, nor are skin diseases common, in spite of the filthy habits of the people. The most dreaded of all diseases is smallpox. Inoculation is habitually used. Ophthalmia is very prevalent and severe.

*History.*—The seat of the princes whose family raised Tibet to a position among the powers of Asia was originally on the Yarlung river, in the extreme east of the region now occupied by Tibetan tribes. It was transplanted to Lhasa in the 7th century by the king Strong-dsan-gampo, conqueror, civilizer, and proselytizer, the founder of Buddhism in Tibet, the introducer of the Indian alphabet. On the three-peaked crag now occupied by the palace-monastery of the Great Lama this king is said to have established his fortress, whilst he founded in the plain below temples to receive the sacred images, brought respectively from Nepal and from China by the brides to whom his own conversion is attributed.

Tibet endured as a conquering power some two centuries, and the more famous among the descendants of the founder added to the city. This-rong-de-tsan (who reigned 740-786) is said to have erected a great temple-palace of which the basement followed the Tibetan style, the middle story the Chinese, and the upper story the Indian—a combination which would aptly symbolize the elements that have moulded the culture of Lhasa, such as it is. His son, the last of the great orthodox kings, in the next century, is said to have summoned artists from Nepal and India, and among many splendid foundations to have erected a sanctuary (at Samayé) of vast height, which had nine stories, the three lower of stone, the three middle of brick, the three uppermost of timber. With this king the glory of Tibet and of ancient Lhasa reached its zenith, and in 822 an obelisk recording his treaty on equal terms with the Great Tang emperor of China was erected in the city. There followed dark days for Lhasa and the Buddhist Church in the accession of this king's brother Langdharma, who has been called the Julian of the Lamas. This king rejected the doctrine, persecuted and scattered its ministers, and threw down its temples, convents, and images. It was more than a century before Buddhism recovered its hold, and its convents were rehabilitated over Tibet. The country was then split into an infinity of petty states, many of them ruled from the convents by wau-like ecclesiastics; but, though the old monarchy never recovered, Lhasa seems to have maintained some supremacy, and probably never lost its claim to be the chief city of that congeries of principalities, with a common faith and a common language which was called Tibet.

The Arab geographers of the 10th century speak of Tibet, but it is without real knowledge, and none speak of any city that we can identify with Lhasa. The first passage in any Western author in which such identification can be probably traced occurs in the narrative of Friar Odorico of Pordenone (c. 1330). This remarkable traveller's route from Europe to India, and thence by sea to China, can be traced satisfactorily, but of his journey homeward through Asia the indications are very fragmentary. He speaks, however, on this return journey of the realm of Tibet, which lay on the confines of India proper:—"The folk of that country dwell in tents made of black felt. But the chief and royal city is all built with walls of black and white, and all its streets are very well paved. In this city no one shall dare to shed the blood of any, whether man or beast, for the reverence they bear a certain idol that is there worshipped. In that city dwelleth the *Abassi*, i.e., in their tongue the pope, who is the head of all the idolators, and who has the disposal of all their benedictions such as they are after their manner."

We know that Kublāi Khan had constituted a young prince of the Lama Church, Mati Dhwaia, as head of that body, and tributary ruler of Tibet, but besides this all is obscure for a century. This passage of Odorico shows that such authority continued under Kublāi's descendants, and that some foreshadow of the position since occupied by the Dalai Lama already existed. But it was not till a century after Odorico that the strange heredity of the dynasty of the Dalai Lamas of Lhasa actually began. And in the first two centuries of its existence the residence of these pontiffs was rather at Brebung or Sera than at Lhasa itself, though the latter was the centre of devout resort. A great event for Lhasa was the conversion, or reconversion, of the Mongols to Lamaism (c. 1577), which made the city the focus of sanctity and pilgrimage to so vast a tract of Asia. It was in the middle of the 17th century that Lhasa became the residence of the Dalai Lama. A native prince, known as the Tsampo, with his seat at Shigatze, had made himself master of southern Tibet, and threatened to absorb the whole. The fifth Dalai Lama, Nawang Lobsang, called in the aid of a Calmuck prince, Gushi Khan, from the neighbourhood of the Koko-nur, who defeated and slew the Tsampo and made over full dominion in Tibet to the Lama (1643). The latter now first established his court, and built his palace, on the rock-site of the fortress of the ancient monarchy, which apparently had fallen into ruin, and to this he gave the name of *Potala*.<sup>1</sup>

In the time of this Dalai Lama, Lhasa was visited for the first time by European travellers. In 1624 Antonio d'Andrade, a Portuguese Jesuit, had penetrated to Tibet through the Gangetic Himalaya, and returned the following year with a coadjutor. But the place which he reached was *Capu ingue* in the kingdom of *Cogus*, as he calls it, i.e., Chaprang in the province of Gugé on the Tibetan Sutiéj, and he never got nearer Lhasa. In June 1681 the Jesuit

<sup>1</sup> This name is absurdly explained by Abbé Huo as *Buddha-la*—"hill of Buddha." This is not even a possible etymology, for, whilst the actual term *Buddha* seems never to be used untranslated in Tibet, one may discern from Huo's own book that *la* means, not "a hill," but "a pass" over mountains. The name seems to be really taken from the classical traditions of the Buddhists. *Potala*, "the harbour" (the *Pattala* of the Greeks, the modern Hyderabad on the Indus), was in legend the royal seat, for more than a hundred generations, of the Sakya progenitors of Gautama Buddha (see *Choima de Kertana d'our*, *As. Soc. Bengal*, ii. 390).

fathers, Albert D'Orville and John Grueber, started from Peking, and, by the way of Siningfu and the Koko-nur, reached Lhasa, where they stayed a month, and then went on through Nepal to India. The extracts from Grueber's narrative, given by Athanasius Kircher in his *China Illustrata* (Amst., 1687), are accompanied by a drawing of Potala which, though meagre, appears to be genuine, and is the only European representation in existence of that Tibetan Vatican.

The founder of Potala died in 1682, and his death was followed by events which brought on a time of trouble. He had appointed as "regent" or civil administrator (*Tsari*, or *Deba*), one supposed to be his own natural son. This remarkable personage, Sangje Gyamtso, of great ambition and accomplishment, still renowned in Tibet as the author of some of the most valued works of the native literature, concealed the death of his master, asserting that the latter had retired, in mystic meditation or trance, to the upper chambers of the palace. The government continued to be carried on in the Lama's name by the regent, who leagueed with Galdan Khan of Dzungaria against the Chinese (Manchu) power. It was not till the great emperor Kang-hi was marching on Tibet that the death of the Lama, sixteen years before, was admitted. A solemn funeral was then performed, at which 108,000 lamas assisted, and a new incarnation was set up in the person of a youth of fifteen. This young man was the scandal of the Lamaïte Church in every kind of evil living and debauchery. But it was under him and the regent Sangje Gyamtso that the Potala palace attained its present scale of grandeur, and that most of the other great buildings of Lhasa were extended and embellished. In 1705 a Calmuck prince, Latsan Khan, great grandson of Gushi Khan, taking the renowned name of Jenghiz Khan, made himself master of Tibet, and put to death both the crafty regent and the dissolute lama whom he had set up. The Dzungarians crossed the northern desert in 1717, and stormed Lhasa, but were in turn driven out by the army of Kang-hi in 1720, and from that time the Chinese power, though, as elsewhere, it has been at times severely shaken, has never quite lost its hold of Tibet.

It was in the midst of these troubled times (1708) that a Capuchin mission entered Lhasa. It was unfortunate in the death of its successive heads, and from about 1712 it was abandoned for several years, but after an interval the Capuchins reappeared, twelve in number, reaching Lhasa by Nepal in 1720. Nothing almost was heard of them till the head of the mission, P. Orazio della Penna, appeared at Rome in 1735 to report that nine were dead, and to ask reinforcement. He returned with nine more, carrying presents to the Grand Lama and the so-called "king of Tibet." In 1742 he reported his safe arrival, and that the presents were well received. Called to Nepal, where there was a branch of the mission, he died there in 1747. We possess some of the results collected by this mission in an excellent short treatise on Tibet by P. Orazio himself, as well as in the extraordinary hodge-podge of crude philology, rubbish, and valuable facts (like fossils imbedded in a bank of mud), the *Alphabetum Tibetanicum* of the Augustine monk Ant. Giorgi (*Rome*, 1762). The mission seems to have been expelled from Tibet in 1754, and found refuge for a time in Nepal. Some fifty volumes, the relics of the mission library, were in 1817 recovered from Lhasa by Mr Bryan Hodgson, through the courtesy of the Grand Lama himself, and were transmitted as an offering to Pope Pius IX., then in the first bloom of reputation.

In 1716, moreover, two Jesuits, P. Ippolito Desideri of Pistoia, and P. Freyre, a Portuguese, reached Lhasa by way of Kashmir, Ladak, and the enormous journey from Ladak by the holy lakes and the valley of the Tsampu. Desideri remained at Lhasa till April 1721, witnessing the capture of Lhasa successively by Dzungar and Chinese. Of the moderation of the latter, and their abstinence from all outrage or plunder, he speaks highly. His departure was due to controversies between the Jesuits and Capuchins at Rome, which caused an order to be issued for his retirement from Tibet. An interesting letter from him, dated April 10, 1716, is printed in the *Lettres Édiifiées*, Rec. xv., but a large MS. volume of his observations during his residence in Tibet is still unpublished. The next European visitor was Samuel Van de Putte of Flushing, an L.L.D. of Leyden, whose thirst for travel carried him through India to Lhasa, where he is said to have resided a long time, to have acquired the language, and to have become intimate with some of the lamas. After travelling from Lhasa to Peking with a lama mission he returned, again by Lhasa, to India, and was an eye-witness of the sack of Delhi by Nadir Shah in 1737. Unhappily he ordered his papers to be burnt after his death, and the knowledge that such a traveller must have accumulated died with him. We pass on to 1811-12 when the first (and last) English visit to Lhasa occurred. The traveller was Thomas Manning, a Cambridge man of Caius College, who had been long devoted to Chinese studies, the "friend M." of Charles Lamb, from whom "Elia" professes to have got that translation of a Chinese MS. which furnished the immortal dissertation on roast pig. After residing some years at Canton, Manning went to Calcutta, bent on reaching the interior of China through Tibet, since from the seaboard it was sealed. He actually did reach Lhasa, stayed there about five months, and had several interviews with the Dalai Lama, but was compelled to return to India. He never

published anything regarding his journey, and the very fact of its occurrence was known to few, when his narrative was printed, through the praiseworthy zeal of Mr C. Markham, in 1876. The man had given the reins to his own eccentricities till he seemed to have lost all power of seriousness, and the account, though containing some passages of great interest, is most disappointing.

The next travellers to reach Lhasa were Hue and Gabet, French Lazarist priests, who travelled from China the route followed by Grueber and by Van de Putte, *via* Siningfu, and reached Lhasa 29th January 1846. On the 15th of March they were sent off under escort by the rugged road to Sz'-chuen. Hue's book, *Souvenirs d'un Voyage*, &c., is probably still well known, and deserves to be so, for it is one of the most delightful among books of travel. Hue was indeed, not only without science, perhaps without accurate knowledge of any kind, but also without that geographical sense which sometimes enables a traveller to bring back valuable contributions to geographical knowledge though unable to make instrumental observations. He was, however, amazingly clever as a narrator and sketcher of character; and, in this his first work, his ambition to shine had not gained the upper hand as it did fatally in later works. It was Ke-shen, a well-known Chinese statesman, disgraced for making peace with the English at Canton in 1841, and who was then on a special deputation to Lhasa, who ostensibly expelled them. The Tibetan regent, with his enlightened and kindly spirit, is painted by Hue in most attractive colours, and Mr Markham expresses strongly the opinion that the native authorities were most willing to receive strangers, whilst the jealousy that excluded them was Chinese only. Recent experiences of attempts to enter Tibet contradict this view. The lamas, whose rule seems to have become more and more grasping and oppressive, appear to be sensible that their system would easily fall to pieces, and are violently opposed to the passage of Europeans across the Tibetan frontier.

Our latest narrative of a visit to Lhasa is that of the late Pandit Nain Singh, trained as an explorer in the Indian survey department. He reached the city in the course of two most remarkable journeys. In the first, after an intellectual attempt by Nepal, he travelled by the Manasarovar Lake, and the road thence eastward, parallel to the course of the Tsampu, reaching Lhasa 10th January 1866, and leaving it 21st April 1867. On the second journey (1874) he started from Ladak, crossing the vast and elevated plateau by the Tengri-nor and other great lakes, and again reaching Lhasa 18th November. Between these two journeys Lhasa had also been visited by another native explorer in 1872. Nain Singh, by his extraordinary surveys, and by repeated observations of latitude on his first visit, has fixed for us the position of Lhasa. But he also has given an account of his journeys, and of his residence there, which, though brief, is full of intelligence and interest, and appears to be thoroughly trustworthy. This enterprising and deserving man was, on the completion of his journey in 1875, rewarded by the Indian Government with a pension and grant of land, and afterwards received the gold medal of the Roy Geog. Soc. and the Companionship of the Star of India. He died early in 1882.

Robet, printed in *Suppl. to Gazette of India*, November 8, 1879; "The Silver Coinage of Tibet," by M. Terrien de la Couperie, in *Annales Chinoises*, 3d ser., vol. i. (H. Y.)

L'HÔPITAL, or L'HOSPITAL, MICHEL DE (c. 1505-1573), chancellor of France from 1560 to 1568, was born near Aigueperse in Auvergne (now Puy-de-Dôme) about the year 1505. His father, who was physician and comptroller of accounts to the constable Charles de Bourbon, sent him to study at Toulouse, whence at the age of eighteen he was driven by the evil fortunes of the family patron, after suffering arrest and imprisonment, to Padua, in which university he studied law and letters for about six years. On the completion of his studies he joined his father at Bologna, and afterwards, the constable having died, went to Rome in the suite of Charles V. For some time he held the position of auditor of the rota at Rome, but in 1534, encouraged by the fair promises of Cardinal de

<sup>1</sup> See Walker's *Report* for 1873-74.

Grammont, he returned to France. The death of his patron soon afterwards seriously impaired his prospects; but after he had entered himself of the Parisian bar, his marriage, in 1537, to a daughter of the lieutenant-criminel procured for him the post of counsellor to the parliament of Paris. This office he held until 1547, when he was sent by Henry II. on a mission to Bologna, where the council of Trent was at that time sitting; after sixteen months of wearisome inactivity there, he was by his own desire recalled at the close of 1548. L'Hôpital now for some time held the position of "chancellor" in the household of the princess Margaret, duchess of Berri, and in 1554 he was made superintendent of the royal finances. In 1559 he accompanied his mistress, now duchess of Savoy, to Nice, where, on the following year, tidings reached him that he had been chosen to succeed Olivier in the chancellorship of France. One of his first acts after entering on the duties of his office (in July 1560) was to cause the parliament of Paris to register the edict of Romorantin, of which he is sometimes, but erroneously it would seem, said to have been the author. Designed as it was to protect so-called heretics from the secret and summary methods of the Inquisition, it certainly had his sympathy and approval. In accordance with the consistent policy of inclusion and toleration by which the whole of his official life was characterized, he induced the council to call the Assembly of Notables, which met at Fontainebleau in August 1560 and agreed that the States General should be summoned, all proceedings against heretics being meanwhile suppressed, pending the reformation of the church by a general or national council. The States General met in December; the edict of Orleans (July 1561) followed, and finally, after the colloquy of Poissy, that of January 1562, the most liberal (except that of Nantes) ever obtained by the Protestants of France. Its terms, however, were not carried out, and during the war which was the inevitable result of the massacre of Vassy in May, L'Hôpital, whose dismissal had been for some time urged by the papal legate Hippolytus of Este, found it necessary to retire to his estate at Vignay near Étampes, whence he did not return until after the pacification of Amboise (March 19, 1563). It was by his advice that Charles IX. was declared of age (August 17, 1563) at Rouen, a measure which really increased the power of Catherine de' Medici; and it was under his influence also that the parliament of Paris in 1561 refused to sanction the publication of the acts of the council of Trent, on account of their inconsistency with the Gallican liberties. In 1564-66 he accompanied the young king on an extended tour through France; and in 1566 he was instrumental in the promulgation of an important edict for reform of abuses in the administration of justice. The renewal of the religious war in September 1567, however, was at once a symptom and a cause of diminished influence to L'Hôpital, and in February 1568 he obtained his letters of discharge, which were registered by the parliament on May 11, his titles, honours, and emoluments being reserved to him during the remainder of his life. Henceforward he lived a life of unbroken literary seclusion at Vignay, his only subsequent public appearance being by means of a "mémoire" which he addressed to the king in 1570 under the title *Le but de la guerre et de la paix, ou Discours du chancelier L'Hospital pour exhorter Charles IX. à donner la paix à ses sujets*. Though not exempt from considerable danger, he passed in safety through the troubles of the St Bartholomew, but did not long survive them. His death took place either at Vignay or at Bélesbat (Courdimanche, Étampes) on March 13, 1573.

After his death Fabrac, assisted by De Thon and Scévole de Sainte-Marthe, collected a volume of the *Œuvres* of L'Hôpital, and in 1585 his grandson published *Epistolurum seu Sermonum*

*libri sex*. The complete *Œuvres de l'Hôpital* were published for the first time by Dufey (5 vols. 8vo, Paris, 1824-25). They include his "Harangues" and "Remonstrances," the *Epistoles*, the *Mémoire* to Charles IX., a *Traité de la Reformation de la Justice*, and the will of L'Hôpital. Haag (*France Prot.*, vii. p. 83) gives the titles of several MSS. still unpublished. Villemain wrote a *Vie de L'Hôpital*, which has recently been reprinted (1874), and there are monographs also by Taillandier (1861) and by Dupré-Lasal (1876).

LIAU-YANG, or LEAOU-YANG, a city of China, formerly the chief town of the province of Liau-tung or Shing-king (southern Manchuria), and still a place of considerable mark, 35 miles south of Moukden. It is situated in a rich cotton district, and carries on no small trade. The walls include an area about 2½ miles long by 2 miles broad, and there are pretty extensive suburbs; but a good deal even of the enclosed area is under cultivation. The population is estimated at 80,000.

LIBANIUS, a Sophist, was the most distinguished Greek writer of the 4th century A.D. He was born at Antioch between 314 and 316. He studied at Athens, and spent most of his earlier manhood in Constantinople and Nicomedia. His private classes at Constantinople were much more popular than those of the public professors; and their jealousy found means of having him expelled from Constantinople in 346 on the charge of studying magic. He was recalled from Nicomedia after five years. Ill health obliged him to retire to Antioch, where he spent the later part of his life. Though a pagan by religion, he enjoyed the favour of the Christian emperors. When Julian restored paganism as the state religion, Libanius showed no intolerance. Among his pupils he numbered St John Chrysostom and St Basil. His works, consisting chiefly of orations, declamations on set topics, and letters, are very voluminous, and have not yet been published in one single edition. He devoted much time to the study of the classical Greek writers, on whom his style is modelled with considerable success.

The best edition of the orations and declamations is Reiske's, of the letters Wolf's. See Westermann, *Gesch. d. Griech. Beredsamkeit*; Bernhardt's and other histories of Greek literature; Forster, *Zur Schriftstellerei des Libanius*, and articles in *Hermes*, vols. ix. and x.

LIBAU (*Leepaja* of the Letts), a port of Russia, on the Baltic Sea, in the government of Courland and district of Grobin, 143 miles by rail south-west of Riga. It is situated at the northern extremity of a narrow sandy peninsula which separates Lake Libau (12 miles long and 2 miles wide) from the Baltic Sea. The town is well built of stone, with good gardens, and has a gymnasium and more than twenty different schools, cigar manufactories, machine works, and a small wharf. The sea throwing up a good deal of amber, many inhabitants are engaged in the fabrication of small articles of that substance. The harbour of Libau was 2 miles south of the town until a canal was dug through the peninsula in 1697; but this canal is liable to be silted up, and the depth at the bar is only 9 feet, or even 6 feet during south-west winds, so that larger ships must lie in the open roadstead. Libau being the most southern Baltic port in Russia has the advantage of freezing only for a few weeks during the winter. Since being brought, in 1872, into railway connexion with Moscow, Orel, and Kharkoff, it has become an important Russian port, and competes with the northern ports of Prussia, the exports already exceeding by 100,000 tons those from Königsberg. In 1879 the port of Libau was visited by 1976 ships, and the export of corn, flax, hempseed, and linseed has reached 28,212,600 roubles (about £2,822,000), against 1,980,000 roubles and 367 ships in 1872. The merchants carry on an active trade in grain and flax, making their purchases directly in southern Russia; their warehouses are numerous, spacious, and well built. The

yearly fair has some importance for the neighbouring districts. The town is also a watering-place, yearly visited by several hundreds of persons. Population in 1881, 27,900; with military and railway-servants, 30,000.

The port of Libau, *Lyra portus*, is mentioned as early as 1263; it then belonged to the Livonian order. In 1418 it was burnt by Lithuanians, and in 1560 it was mortgaged by the grandmaster of the order to the Prussian duke Albert. It was annexed to Russia in 1795.

**LIBEL AND SLANDER** are the terms employed in English law to denote injurious attacks upon a man's reputation or character by words written or spoken, or by equivalent signs. In most early systems of law we find verbal injuries treated as a criminal or quasi-criminal offence, the essence of the injury lying not in pecuniary loss, which may be compensated by damages, but in the personal insult which must be atoned for,—a vindictive penalty coming in the place of personal revenge. By the law of the XII. Tables, the composition of scurrilous songs and gross noisy public affronts were punished by death. Minor offences of the same class seem to have found their place under the general conception of *injuria*, which included ultimately every form of direct personal aggression which involved contumely or insult. In the later Roman jurisprudence, which has, on this point, exercised considerable influence over modern systems of law, we find verbal injuries dealt with in the edict under two heads. The first comprehended defamatory and injurious statements which were made in a public manner (*convicium contra bonos mores*). In this case the essence of the offence lay in the unwarrantable public proclamation, in the contumely which was offered to a man before his fellow-citizens. In such a case the truth of the statements was no justification for the unnecessarily public and insulting manner in which they had been made. The second head included defamatory statements which were made in private, and in this case the offence lay in the imputation itself, not in the manner of its publication. The truth was therefore a sufficient defence, for no man had a right to demand legal protection for a false reputation. Even belief in the truth was enough, because it took away the intention which was essential to the notion of *injuria*. The law thus aimed at giving sufficient scope for the discussion of a man's character, while at the same time it protected him from needless insult and pain. The remedy for verbal injuries was long confined to a civil action for a money penalty, which was estimated according to the gravity of the case, and which, although vindictive in its character, doubtless included practically the element of compensation. But a new remedy was introduced with the extension of the criminal law, under which many kinds of defamation were punished with great severity. We find at the same time increased importance attached to the publication of defamatory books and writings, the *libri* or *libelli famosi*, from which we derive our modern use of the word libel; and under the later emperors the latter term came to be specially applied to anonymous accusations or pasquils, the dissemination of which was regarded as peculiarly dangerous, and visited with very severe punishment, whether the matter contained in them were true or false.

The earlier history of the English law of defamation is somewhat obscure. Civil actions for damages seem to have been tolerably frequent so far back as the reign of Edward I. There was no distinction drawn between words written and spoken. When no pecuniary penalty was involved such cases fell within the old jurisdiction of the ecclesiastical courts, which was only finally abolished during the present reign. It seems, to say the least, uncertain whether any generally applicable criminal process was in use. The crime of *scandalum magnatum*, spreading false reports about the magnates of the realm, was established by statutes,

but the first fully reported case in which libel is affirmed generally to be punishable at common law is one tried in the Star Chamber in the reign of James I. In that case no English authorities are cited except a previous case of the same nature before the same tribunal; the law and terminology appear to be taken directly from Roman sources, with the insertion that libels tended to a breach of the peace; and it seems probable that that not very scrupulous tribunal had simply found it convenient to adopt the very stringent Roman provisions regarding the *libelli famosi* without paying any regard to the Roman limitations. From that time we find both the criminal and civil remedies in full operation, and will now consider how the law stands with regard to each at the present time.

*Civil Law.* The first important distinction we encounter is that between slander and libel, between the oral and written promulgation of defamatory statements. In the former case the remedy is limited. The law will not take notice of every kind of abusive or defamatory language. It must be shown either that the plaintiff has suffered actual damage as a direct consequence of the slander, or that the imputation is of such a nature that we are entitled to infer damage as a necessary consequence. The special damage on which an action is founded for slanderous words must be of the nature of pecuniary loss. Loss of reputation or of position in society, or even illness, however clearly it may be traced to the slander, is insufficient. When we cannot prove special damage, the action for slander is only allowed upon certain strictly defined grounds. These are the imputation of a crime or misdemeanour which is punishable corporally, *e.g.* by imprisonment; the imputation of a contagious or infectious disease; statements which tend to the dishonour of an apparent heir (other cases of slander of title when the party is in possession requiring the allegation of special damage); and lastly, slanders directed against a man's professional or business character, which tend directly to prejudice him in his trade, profession, or means of livelihood. In the latter case the words must either be directly aimed at a man in his business or official character, or they must be such as necessarily to imply unfitness for his particular office or occupation. Thus words which merely reflect generally upon the moral character of a tradesman or professional man are not actionable, but they are actionable if directed against his dealings in the course of his trade or profession. But, in the case of a merchant or trader, an allegation which affects his credit generally is enough, and in the same way it has been held that statements are actionable which affect the ability or moral characters of persons who hold offices, or exercise occupation which require a high degree of ability, or infer peculiar confidence. In every case the plaintiff must have been at the time of the slander in the actual exercise of the occupation or enjoyment of the office with reference to which the slander is supposed to have affected him.

The action for libel is not restricted in the same way as that for slander. Originally, as we have seen, there appears to have been no essential distinction between them, but the establishment of libel as a criminal offence had probably considerable influence, and it soon became settled that written defamatory statements, or pictures and other signs which bore a defamatory meaning, implied greater malice and deliberation, and were generally fraught with greater injury than those which were merely made by word of mouth. The result has been that the action for libel is not limited to special grounds, or by the necessity of proving special damage. It may be founded on any statement which disparages a man's private or professional character, or which tends to hold him up to hatred, contempt, or ridicule. In one of the leading cases, for example, the

plaintiff obtained damages because it was said of him that he was a hypocrite, and had used the cloak of religion for unworthy purposes. In another case a charge of ingratitude was held sufficient. In civil cases the libel must be published by being brought by the defendant under the notice of a third party, and it has even been held that it is sufficient if this has been done by gross carelessness, without deliberate intention to publish. Every person is liable to an action who is concerned in the publication of a libel, whether he be the author, printer, or publisher; and the extent and manner of the publication, although not affecting the ground of the action, is a material element in estimating the damages.

It is not necessary that the defamatory character of the words or writing complained of should be apparent on their face. They may be couched in the form of an insinuation, or may derive their sting from a reference to circumstances understood by the persons to whom they are addressed. In such a case the plaintiff must make the injurious sense clear by an averment called an innuendo, and it is for the jury to say whether the words bore the meaning thus ascribed to them.

In all civil actions for slander and libel the falsity of the injurious statements is an essential element, so that the defendant is always entitled to justify his statements by their truth; but when the statements are in themselves defamatory, their falsity is presumed, and the burden of proving their truth is laid upon the defendant. There are however, a large class of false defamatory statements, commonly called privileged, which are not actionable on account of the particular circumstances in which they are made. The general theory of law with regard to these cases is this. It is assumed that in every case of defamation intention is a necessary element; but in the ordinary case, when a statement is false and defamatory, the law presumes that it has been made or published with an evil intent, and will not allow this presumption to be rebutted by evidence or submitted as matter of fact to a jury. But there are certain circumstances in which the natural presumption is quite the other way. There are certain natural and proper occasions on which statements may be made which are in themselves defamatory, and which may be false, but which naturally suggest that the statements may have been made from a perfectly proper motive and with entire belief in their truth. In the cases of this kind which are recognized by law, the presumption is reversed. It lies with the plaintiff to show that the defendant was actuated by what is called *express malice*, by an intention to do harm, and in this case the question is not one of legal inference for the court, but a matter of fact to be decided by the jury. Although, however, the theory of the law seems to rest entirely upon natural presumption of intention, it is pretty clear that in determining the limits of privilege the courts have been almost wholly guided by considerations of public or general expediency.

In some cases the privilege is absolute, so that we cannot have an action for defamation even although we prove express malice. Thus no action of this kind can be maintained for statements made in the course of judicial proceedings if they are in any sense relevant to the matter in hand. In the same way no statements or publications are actionable which are made in the ordinary course of parliamentary proceedings. Papers published under the authority of parliament are protected by a special Act, 3 & 4 Vict. c. 9, which was passed after a decree of the law courts adverse to the privilege claimed. The reports of judicial and parliamentary proceedings stand in a somewhat different position, which has only been attained after a long and interesting conflict. The general rule now is that all reports of parliamentary or judicial proceedings

are privileged in so far as they are honest and impartial. Even *ex parte* proceedings, in so far as they take place in public, now fall within the same rule. But if the report is garbled, or if part of it only is published, the party who is injured in consequence is entitled to maintain an action, and to have the question of malice submitted to a jury. Comments on subjects of public interest, on the proceedings of courts or public bodies, on publications, exhibitions, and on persons who have in any way chosen to invite the public attention, fall within a similar rule. The public interest demands that on all these subjects a fair latitude for discussion should be permitted; the critic is entitled to the utmost liberty so long as he expresses nothing more than his honest opinion of the subject before him, but if it can be proved that he has used false and defamatory language out of malice, and especially if he has travelled beyond the facts which are properly before the public, he is no longer protected by his privilege. In private life a large number of statements are privileged so long as they remain matters of strictly private communication. It is difficult to define the limits of private privilege without extensive reference to concrete cases; but generally it may be said that it includes all communications which are made in performance of a duty not merely legal but moral or social, answers to *bona fide* inquiries, communications made by persons in confidential relations regarding matters in which one or both are interested, and even statements made within proper limits by persons in the *bona fide* prosecution of their own interest. Common examples of this kind of privilege are to be found in answer to inquiries as to the character of servants or the solvency of a trader, warnings to a friend, communications between persons who are jointly interested in some matters of business. But in every case we must be careful not to exceed the limits of publication required by the occasion, or otherwise the privilege is lost. Thus defamatory statements may be privileged when made to a meeting of shareholders, but not when published to others who have no immediate concern in the business.

In a few instances in which an action cannot be maintained even by the averment of malice, the plaintiff may maintain an action by averring not only malice but also want of reasonable and probable cause. The most common instances of this kind are malicious charges made in the ordinary course of justice and malicious prosecutions. In such cases it would be contrary to public policy to punish or prevent every charge which was made from a purely malicious motive, but there is no reason for protecting accusations which are not only malicious, but destitute of all reasonable probability.

*Criminal Law.*—Publications which are blasphemous, immoral, or seditious are frequently termed libels, and are punishable both at common law and by various statutes. The matter, however, which constitutes the offence in these publications lies beyond our present scope. Libels upon individuals may be prosecuted by criminal information or indictment, but there can be no criminal prosecution for slander. So far as concerns the definition of libel, and its limitation by the necessity of proving in certain cases express malice, there is no substantial difference between the rules which apply to criminal prosecutions and to civil actions, with the one important exception (now considerably modified) that the falsity of a libel is an essential element of the offence, whereas in civil law the matter alleged would not permit application of this rule. The rule seems chiefly due to the inapplicability of certain modes of publication, but has been maintained for various reasons of general policy, and accordingly

view that one main reason for punishing a libel was its tendency to provoke a breach of the peace. The same view has occasioned a difference in the publication required in civil and criminal actions. It is enough in criminal law that the libel has been published to the party against whom it is directed, if it is averred that it is intended or calculated to produce a breach of the peace. Important alterations, however, have been introduced into this branch of the law by 6 & 7 Vict. c. 96. By that Act any person who maliciously publishes a defamatory libel may be punished by fine or imprisonment or both, the imprisonment not to exceed one year. Any person maliciously publishing a defamatory libel, knowing the same to be false, is liable to fine and imprisonment for two years. In every case the truth of the matters charged may be inquired into if it be pleaded, but the truth does not amount to a defence unless it is also proved that the publication was for the public benefit; and if, after such plea, the defendant is convicted, it is competent to the court to consider whether the guilt of the defendant is mitigated or aggravated by the plea, and the evidence given in relation to it. By the same Act a defendant is protected from publication of libels without his knowledge, authority, or consent, if the publication did not arise from the want of due care and caution on his part. The court are further authorized to award costs to the defendant in any information or indictment at the instance of a private prosecutor.

An important dispute about the powers of the jury in cases of libel arose during last century in connexion with some well known trials for seditious libels. The point is familiar to readers of Macaulay in connexion with the trial of the seven bishops, but the cases in which it was brought most prominently forward, and which led to its final settlement, were those against Woodfall (the printer of *Junius*), Wilkes, and others, and especially the case against Shipley, the dean of St Asaph (21 St. Tr. 925), in which the question was fought by Mr Erskine with extraordinary energy and ability. The controversy turned upon the question whether the jury were to be strictly confined to matters of fact which required to be proved by evidence, or whether in every case they were entitled to form their own opinion upon the libellous character of the publication and the intention of the author. There could be no doubt of course that the jury, if they pleased, had it in their power to return a general verdict of guilty or not guilty, but both in theory and practice they were subject in law to the directions of the court, and had to be informed by it as to what they were to take into consideration in determining upon their verdict (see *JURY*). There is no difficulty about the general application of this principle in criminal trials. In a case of murder, for example, the judge directs the jury that if they are satisfied the accused did so and so they ought to find him guilty. He directs them, not merely as to the definition of the crime, but as to the particular facts which fall within that definition. If the crime is one which is inferred by law from certain facts, they are only concerned with these facts, and must accept the construction which is put upon them by law. Applying these principles to the case of libel, juries were directed that it was for the court to determine whether the publication fell within the definition of libel, and whether the case was one in which malice was to be inferred by construction of law. If the case were one in which malice was inferred by law, the only facts left to the jury were the fact of publication and the meaning averred by imputations; they could not go into the question of intention unless the case were one of privilege, in which express malice had to be proved. In general principle, therefore, the decisions of the court were in accordance with the principles of criminal law. But there were

undoubtedly some peculiarities in the case of libel. The sense of words, the inferences to be drawn from them, and the effect which they produce are not so easily defined as gross matters of fact. They seem to belong to those cases in which the impression made upon a jury is more to be trusted than the decision of a judge. And further, owing to the mode of procedure, the defendant was often punished before the question of law was determined. But nevertheless the question would scarcely have been raised had the libels related merely to private matters. The real ground of dispute was the liberty to be accorded to political discussion. Had the judges taken as wide a view of privilege in discussing matters of public interest as they do now, the question could scarcely have arisen; for Erskine's whole contention really amounted to this, that the jury were entitled to take into consideration the good or bad intent of the authors, which is precisely the question which would now be put before them in any matter which concerned the public. But at that time the notion of a special privilege attaching to political discussion had scarcely arisen, or was at least confined within very narrow limits, and the cause of free political discussion seemed to be more safely entrusted to juries than to courts. The question was finally settled by Mr Fox's Libel Act (32 Geo. III. c. 60), by which the jury were entitled to give a general verdict on the whole matter put in issue.

*Scotch Law.*—In Scotch law there were originally three remedies for defamation. It might be prosecuted by or with the concurrence of the lord advocate before the Court of Justiciary; or, secondly, a criminal remedy might be obtained in the commissary (ecclesiastical) courts, which originally dealt with the defender by public retraction or penance, but subsequently made use of fines payable to their own procurator or to the party injured, these latter being regarded as solatium to his feelings; or, lastly, an action of damages was competent before the Court of Session, which was strictly civil in its character, and aimed at the reparation of patrimonial loss. The first remedy has fallen into disuse; the second and third (the commissary courts being now abolished) became mixed up together, and are represented by the present action for damages or solatium. Originally the action before the Court of Session was strictly for damages—founded, not upon the *animus injuriarum*, but upon culpa, and could be defended by proving the truth of the statements. But in time the Court of Session began to assume the original jurisdiction of the commissary courts, and entertained actions for solatium in which the *animus injuriarum* was a necessary element, and to which, as in Roman law, the truth was not necessarily a defence. Ultimately the two actions got very much confused. We find continual disputes as to the necessity for the *animus injuriarum* and the applicability of the plea of *veritas contraria*, which arose from the fact that the courts were not always conscious that they were dealing with two actions, to one of which these notions were applicable, and to the other not. On the introduction of the jury court, presided over by an English lawyer, it was quite natural that he, finding no very clear distinction maintained between damage and solatium, applied the English plea of truth as a justification to every case, and retained the *animus injuriarum* both in ordinary cases and cases of privilege in the same shape as the English conception of malice. The leading and almost only differences between the English and Scotch law now are that the latter makes no essential distinction between oral and written defamation, that it practically gives an action for every case of defamation oral or written upon which in England a civil action might be maintained for libel, and that it possesses no criminal remedy. In consequence of the latter defect and the indiscriminate application of the plea of veritas to every case both of damages and solatium, there appears to be at present no remedy in Scotland even for the wildest and most needless publication of offensive statements if only they are true.

*American Law.*—In this as in so many other departments the American law scarcely if at all differs from that of England. In so far indeed as the common law is concerned, they may be said to be substantially identical. The principal statutes which have altered the English criminal law, such as Mr Fox's Act, and 6 & 7 Vict. c. 96, are also represented by equivalent legislation in most American States. (A. G.)

**LIBER AND LIBERA**, among the Romans, were a pair of deities, male and female, in whose worship two very different phases exist side by side. In the country feast of the vintage, and the city festival of March 17th called

*Liberia*, we find purely Italian ceremonial unaffected by Greek religion. The country festival was a great merry-making, where the first-fruits of the new must were offered to the gods. It was full of unbridled rejoicing, and characterized by the grossest symbolism, in honour of the fertility of nature. It is usual to refer the name *Liber* to the free unrestrained character of his worship. In the city festival, growing civilization had impressed a new character on the primitive religion, and connected it with the framework of society. At this time the youths laid aside the boy's *toga pretexta* and assumed the man's *toga libera* or *virilis*. Cakes of *far*, honey, and oil (*liba*) were offered to the two gods at this festival. *Liber* is often invoked as *Liber Pater*, and we find even the expression *Jupiter Liber*, taking us back to the primitive stage of religion when no divine hierarchy of gods had been elaborated, and when *Liber* and *Libera* were in the sphere of their cultus the sole god and goddess. Originally *Liber* is probably only an epithet of *Jupiter*.

At an early period the Hellenic religion of *Demeter*, common to all the Greek colonies of Italy and Sicily, spread to Rome; then *Liber* and *Libera* were identified with *Dionysus* and *Persephone*, and associated with another Italian goddess *Ceres*, who was identified with *Demeter*. At the order of the Sibylline books, a temple was built to these three deities near the *Circus Flaminius*; the whole cultus was borrowed from the Greeks, down even to the terminology, and priestesses were brought from the Greek cities. The temple, *Aedes Cereis*, was founded by *Aulus Postumius*, 496 B.C., and dedicated by *Spurius Cassius*, 493 B.C. The chief festival of this cultus lasted eight days, from the 12th to the 19th of April; it was accompanied by games, called *Ludi Cereales* or *Liberales*. The plebeian *adiles*, appointed about the time when the temple was founded, were closely attached to it, and from that time plebeian liberty continued in intimate relation to the *Aedes Cereis* and the gods there worshipped.

**LIBERIA**, a Negro republic on the Grain Coast of West Africa. Founded in 1822 by American philanthropists for the settlement of freedmen who wished to return to their native land, or to enjoy political and social privileges then denied them in the United States, it remained for twenty-five years under the tutelage of the mother country, but on the 26th July 1847 it was declared independent. In 1848 it was recognized as a sovereign state by Great Britain, which aided it in various ways, and by other Continental powers, and finally in 1861 by the United States. Its nominal boundaries are from the river *Jong*, a tributary of the *Sherbar*, in 7° 35' N. lat., 12° 20' W. long., and the river *San Pedro*, in 4° 45' N. lat., 6° 40' W. long., a distance of 380 miles, the limits of the state in the interior being usually stated at from 80 to 100 miles eastward, though this is unsettled, and the entire area of the country at 24,000 square miles, or 1000 miles less than Holland and Belgium combined. Like that of northern Guinea generally, the Liberian shore is low, but the country rises towards the interior, and is well-wooded and watered by numerous streams. The climate is, however, hot and unhealthy for Europeans, though of late years it has been improved by drainage, and is considered superior to that of any part of the neighbouring coast. The soil is fertile and well suited for the growth of tropical crops, such as cotton, rice, sugar, indigo, yams, ground-nuts, bananas, ginger, cassava, pine-apples, cocoa-nuts, limes, oranges, tamarinds, and the Liberian variety of coffee<sup>1</sup> held in such high esteem. These products, in addition to palm oil, form the main support of the inhabitants, who in

return import arms, ammunition, tobacco, salt provisions, implements of husbandry, cutlery, British cottons, and other manufactured goods. Coffee, palm oil, palm-kernels, rubber, ivory, dye woods, hides, ivory, arrowroot, sugar, cocoa, ginger, and rice form the principal articles of its commerce, which is carried on chiefly with Great Britain, Holland, Hamburg, and America. Copper, gold, iron, and deposits of gum-copal exist, but they are not worked; and all the large wild animals have long since been killed or driven out of the woods. Stock can be kept in the higher lands. The government is modelled on that of the United States, and consists of a president, and a congress composed of a senate of eight members elected for four years, and of a house of representatives of thirteen members elected for three years, in addition to a supreme court, and a cabinet of the American type. One additional representative is given for each additional 10,000 inhabitants by which the population may increase. Military service in the militia is obligatory on every male citizen between the ages of sixteen and fifty, but there is no standing army. There is no established church, and all faiths are equally tolerated. The state is divided into four counties (*Mezurada*, *Grand Bassa*, *Sinoe*, and *Maryland*<sup>2</sup>), and these again into townships, each 64 square miles in area. There are a number of little villages, but the only place of any consequence is *Monrovia*, the capital, containing 13,000 inhabitants, and in appearance very like a town in the southern United States, but in no way remarkable except for the large number of churches within its bounds. Besides *Monrovia* the chief ports are *Robertsport*, *Marshall*, *Edina* or *Buchanan*, *Greenville*, *Sesters River*, *Sasstown*, and *Harper*, and in 1881 foreigners were further permitted to trade at any point to the north of *Robertsport*. The present population of the republic (1882) comprises 18,000 civilized negroes, chiefly of American origin, and 1,050,000 half-wild natives, some of whom are adopting a settled life, and conforming to the habits of their tamed countrymen. Among the more interesting tribes are the *Veis*, the *Bassas*, the *Krus*, and the *Mandingoes*. The American Methodist Episcopal mission dates from 1833, the American Episcopal from 1834, and that of the American Baptists from 1835. The revenue of the state was returned at September 30, 1875, as 111,457 dollars, chiefly derived from customs, the national debt being 500,000 dollars, contracted in England in 1871. Of this neither principal nor interest has been paid. Socially and politically the state cannot be pronounced a marked success. The negroes in America display little desire to throw in their fortunes with it, now that they are free to go whither they list, nor do the barbarous tribes on the border of the republic seem to admire the black parody on a white man's government, which for sixty years has been presented to them. There is now and again a small immigration from the United States, but the Liberian civilization, cut off from the benefit of intercourse with a higher and broader culture, is apt to deteriorate, while neither the climate nor the laws and social surroundings are ever likely to attract many white men to its shores. It is, however, only fair to add that, though internal disorder is too often the rule, the state shows an appreciation of education and religion, and a keen desire to stand well in the good opinion of the powers with which it has relations by accredited representatives. It has formed treaties with most of the European countries, and with Hayti and the United States; and, though it has not paid its debts, successive Governments are in the habit of registering vows to meet this first obligation of a nation towards its neighbours. British coin and an irredeemable

<sup>1</sup> Liberian coffee (see *COFFEE*, vol. vi. p. 110) has been introduced into Brazil, Ceylon, the Dutch Indies, &c. The quantity actually exported from Liberia is comparatively small.

<sup>2</sup> Maryland was originally a separate colony, founded in 1831; it became an independent republic in 1854, and about 1860 was incorporated with its older neighbour.

paper currency are the money chiefly in circulation, but all accounts are kept in United States dollars and cents. The weights employed are also British, except that gold from the interior is bought and sold by the usano = 16 akis = 16,000 cowries = 314·76 grains troy. The gondar-ardeb (7·74 imperial pints), the massuah-ardeb (2·32 imp. gals.), and the kuba (1·788 imp. pints) are also in common use.

See Gurley's *Life of Jehudi Ashmun*, 1835; Stockwell, *The Republic of Liberia*, 1868; Wilson, *West Africa*, 1856; Hutchinson, *Impressions of West Africa*, 1858; Ritter, in *Zeitschrift für allgemeine Erdkunde*, vol. i., 1853; Brown, *Countries of the World*, vol. vi. pp. 123–127, 1881; Bowen, *Central Africa*, 1857; Thomas, *West Coast of Africa*, 1860; "Die Negerrepublik Liberia," in *Unsere Zeit*, vol. iii., 1858; U.S. Consular Reports, 1881.

**LIBERIUS**, pope from 352 to 366, the successor of Julius I., was consecrated according to the *Catalogus Liberianus* on May 22. His first recorded act was, after a synod had been held at Rome, to write to Constantius, then in quarters at Arles (353–54), asking that a council might be called at Aquileia with reference to the affairs of Athanasius; but his messenger Vincentius of Capua, so far from being successful in his mission, was himself compelled by the emperor at a conciliabulum held in Arles to subscribe against his will a condemnation of the orthodox patriarch of Alexandria. In 355 Liberius was one of the few who, along with Eusebius of Vercelli, Dionysius of Milan, and Lucifer of Cagliari, refused to sign the condemnation of Athanasius, which had anew been imposed at Milan by imperial command upon all the Western bishops; the consequence was his relegation to Berea in Thrace, Felix II. (antipope) at the same time being consecrated his successor by three "catascopi hand episcopi," as Athanasius called them. At the end of an exile of more than two years he yielded so far as to subscribe the third Sirmian formula giving up the "homoousion,"—an act which procured his immediate and triumphant return to Rome, but his ever since caused considerable embarrassment to maintainers of the indefectibility of Roman orthodoxy. The remainder of his pontificate was uneventful. He died on September 24, 366, and was succeeded by Damasus I. With the rest of the first sixty popes he shares the title of "Saint." His biographers used to be perplexed by a letter purporting to be from Liberius, in the works of Hilary, in which he seems to write, in 352, that he had excommunicated Athanasius at the instance of the Oriental

bishops; but the document is now held to be spurious. See Hefele, *Conciliengesch.*, i. p. 648 sq.

**LIBOURNE**, the chief town of an arrondissement, and in point of population the second town of the department of Gironde, France, is situated at the confluence of the Isle with the Dordogne, 337 miles by rail south-west from Paris, and 22 miles east from Bordeaux. The sea is 56 miles off, but the tide affects the river so as to admit of vessels of 300 tons burden reaching the town. The Dordogne is here crossed by a stone bridge 492 feet long, and a suspension bridge across the Isle connects Libourne with the adjoining Fronsac, the citadel of which, 235 feet above the sea, was at one time occupied by a palace of Charlemagne, and subsequently became an important fortress. Libourne is regularly built, but has no monuments of much architectural or historical interest; the (restored) Gothic church has a stone spire 232 feet high. On the quay there is a machicolated clock tower which is a remnant of the ramparts of the 14th century; and the town-house, containing a small museum, is a quaint relic of the 16th century. There is a statue of the Duc Decazes, who was born in the neighbourhood. The principal articles of commerce are the wines and brandies of the district, the growths of chief repute being those of St Émilion, a short distance above Libourne, on the right bank of the Dordogne, and of Canon, a little below Fronsac. There is also some trade in yarn, grain, and wool for cooperage. Woollen stuffs and some articles of army outfit are manufactured; and millmaking, tanning, shoemaking, and shipbuilding are also carried on. The harbour is used exclusively by small vessels for the export of wines; the shipping owned in the place does not exceed 2500 tons. The population of Libourne in 1876 was 15,231.

Like other sites at the confluence of important rivers, that of Libourne was appropriated at an early period. Under the Romans *Condat* stood rather more than a mile to the south of the present Libourne, where the old Gothic chapel de *Condat* now is; it was destroyed during the troubles of the 5th century. Rescued by Charlemagne, it was rebuilt, under its present name, and on the site and plan it still retains, by Edward, prince of Wales, in 1270. It suffered considerably in the struggles of the French and English for the possession of Guienne in the 14th century, and again during the religious wars, and finally in the war of the Fronde in the minority of Louis XIV. Nevertheless it ultimately outgrew both its powerful neighbours Fronsac and Saint Émilion, the latter of which is archaeologically one of the most curious spots in France.

## LIBRARIES

### HISTORY AND DESCRIPTION.

#### ANCIENT PERIOD.

**LIBRARIES**, in our modern sense of collections of printed or written literature, imply an advanced and elaborate civilization. If the term be extended to any considerable collection of written documents, they must be nearly as old as civilization itself. The earliest use to which the invention of inscribed or written signs was put was probably to record important religious and political transactions. These records would naturally be preserved in sacred places, and accordingly the earliest libraries of the world were probably temples, and the earliest librarians priests. And indeed before the extension of the arts of writing and reading the priests were the only persons who could perform such work as, e.g., the compilation of the *Annales Maximi*, which was the duty of the pontifices in ancient Rome. The beginnings of literature proper in the shape of ballads and songs may have continued to be conveyed orally only from one generation to another, long after the record of important religious or civil events was regularly committed to writing. The earliest collections of which we know anything therefore were collections of

archives. Of this character appear to have been such famous collections as that of the Medians at Ecbatana or the Persians at Susa. It is not until the development of arts and sciences, and the growth of a considerable written literature, and even of a distinct literary class, that we find collections of books which can be called libraries in our modern sense. It is of libraries in the modern sense, and not, except incidentally, of archives that we are to speak.

The researches which have followed the discoveries of Botta and Layard have thrown unexpected light not only upon the history but upon the arts, the sciences, and the literatures of the ancient civilizations of Babylonia and Assyria. In all these wondrous revelations no facts are more interesting than those which show the existence of extensive libraries so many ages ago, and none are more eloquent of the elaborateness of these forgotten civilizations.

In the course of his excavations at Nineveh in 1850, Assyria, Layard came upon some chambers in the south-west palace, the floor of which, as well as of the adjoining rooms, was covered to the depth of a foot with tablets of clay, covered with cuneiform characters, in many cases so small as to require a magnifying glass. These varied in size

from an inch to a foot square. A great number of them were broken, as Layard supposed by the falling in of the roof, but as the late Mr George Smith thought by having fallen from the upper story, upon which he believed the collection to have been placed. These tablets formed the library of the great monarch Assur-bani-pal—the Sardanapalus of the Greeks—the greatest patron of literature amongst the Assyrians. It is estimated that this library consisted of some ten thousand distinct works and documents, some of the works extending over several tablets. The tablets appear to have been methodically arranged and catalogued, and the library seems to have been thrown open for the general use of the king's subjects.<sup>1</sup> A great portion of this library has already been brought to England and deposited in the British Museum, but it is calculated that there still remain some 20,000 fragments to be gathered up. For further details as to Assyrian libraries, and the still earlier Babylonian libraries from which the Assyrians drew their science and literature, see *BABYLONIA*, vol. iii. p. 191.

#### Egypt.

Of the libraries of ancient Egypt our knowledge is much less full and precise. It seems to be ascertained that the oldest hieroglyphic writings now extant run some centuries farther back than 2000 B.C. We possess a papyrus manuscript which is assigned to the age of Amenophis I. of the 18th dynasty, perhaps about 1600 B.C., and the fabric is so perfect as to point to a much earlier invention.<sup>2</sup> With the invention of papyrus came the age of books. The temples were the centres of literary activity, and to each of them were attached professional scribes who occupied a very respectable position. Their function was regarded as a religious one, for the distinction between religion and science had not yet been made. The sacred books of Thoth—forty-two in number—constituted as it were a complete encyclopædia of religion and science. But they did not forbid speculation, or a wider development of the principles contained in them. So there arose a great mass of literature in the shape of exposition and commentary. To such an extent did this increase that at the time of the Greek conquest of Egypt the Thoth literature is said to have amounted to 36,525 books.<sup>3</sup> Books were collected not only in the temples but also at the tombs of kings. The most famous of these libraries dates from the 14th century B.C., and was the so-called library of King Osymandias, described by Diodorus Siculus, who relates that it bore an inscription which he renders by the Greek words ΨΥΧΗΣ ΙΑΤΡΕΙΟΝ, "the dispensary of the soul." Osymandias has been identified with the great king Ramses I., and the seat of the library is supposed by Wilkinson to have been the Ramesseum, the magnificent palace temple near Thebes.<sup>4</sup> Lepsius thinks he has found the tombs of two of the librarians of Osymandias.<sup>5</sup> According to Eustathius there was also a great collection in a temple at Memphis. A heavy blow was dealt to the old Egyptian literature by the Persian invasion, and many of their books were carried away by the conquerors. They were only delivered from the yoke of Persia to succumb to that of Greece, and henceforward their civilization was dominated by foreign influences. Of the libraries of Greece under the Ptolemies we shall therefore speak a little further on.

#### Greece.

Of the libraries of ancient Greece we have very little knowledge, and such knowledge as we possess comes to us for the most part from late compilers. Amongst those who are known to have collected books are Pisistratus, Polycrates of Samos, Euclid the Athenian, Nicocrates of

Cyprus, Euripides and Aristotle (Athenæus, l. 4). At Cnidus there is said to have been a special collection of works upon medicine. Pisistratus is said to have been the first of the Greeks who collected books on a large scale. Aulus Gellius, indeed, tells us in language perhaps "not well suited to the 6th century B.C.,"<sup>6</sup> that he was the first to establish a public library. The authority of Aulus Gellius is hardly sufficient to secure credit for the story that this library was carried away into Persia by Xerxes and subsequently restored to the Athenians by Seleucus Nicator. Plato is known to have been a collector; and Xenophon tells us of the library of Euthydemus. The library of Aristotle was bequeathed by him to his disciple Theophrastus, and by Theophrastus to Neluus, who carried it to Scepsis, where it is said to have been concealed underground to avoid the literary cupidity of the kings of Pergamus. Its subsequent fate has given rise to much controversy, but, according to Strabo (xiii. pp. 608, 609), it was sold to Apellicon of Teos, who carried it to Athens, where after Apellicon's death it fell a prey to the conqueror Sulla, and was transported by him to Rome. The story told by Athenæus (l. 4) is that the library of Neluus was purchased by Ptolemy Philadelphus. The names of a few other libraries in Greece are barely known to us from inscriptions; of their character and contents we know nothing. If indeed we are to trust Strabo entirely, we must believe that Aristotle was the first person who collected a library, and that he communicated the taste for collecting to the sovereigns of Egypt. It is at all events certain that the libraries of Alexandria were the most important as they were the most celebrated of the ancient world. Under the enlightened rule of the Ptolemies a society of scholars and men of science was attracted to their capital. It seems pretty certain that Ptolemy Soter had already begun to collect books, but it was in the reign of Ptolemy Philadelphus that the libraries were properly organized and established in separate buildings. Ptolemy Philadelphus sent into every part of Greece and Asia to secure the most valuable works, and no exertions or expense were spared in enriching the collections. Ptolemy Euergetes, his successor, is said to have caused all books brought into Egypt by foreigners to be seized for the benefit of the library, while the owners had to be content with receiving copies of them in exchange. Nor did the Alexandrian scholars exhibit the usual Hellenic exclusiveness, and many of the treasures of Egyptian and even of Hebrew literature were by their means translated into Greek. There were two libraries at Alexandria; the larger, in the Bruchium quarter, was in connexion with the Museum, a sort of academy, while the smaller was placed in the Serapeum. The number of volumes in these libraries was very large, although it is difficult to attain any certainty as to the real numbers amongst the widely varying accounts. According to a scholium of Tzetzes, who appears to draw his information from the authority of Callimachus and Eratosthenes, who had been librarians at Alexandria, there were 42,800 volumes or rolls in the Serapeum and 490,000 in the Bruchium.<sup>7</sup> This enumeration seems to refer to the librarianship of Callimachus himself under Ptolemy Euergetes. In any case the figures agree tolerably well with those given by Aulus Gellius<sup>8</sup> (700,000) and Seneca<sup>9</sup> (400,000). It should be observed that, as the ancient roll or volume usually contained a much smaller quantity of matter than a modern book—so that, e.g., the history of Herodotus might form nine "books" or volumes, and the *Iliad* of Homer twenty-four—these numbers must be dis-

counted for the purposes of comparison with modern collections.<sup>1</sup> The series of the first five librarians at Alexandria appears to be pretty well established as follows:—Zenodotus, Callimachus, Eratosthenes, Apollonius, and Aristophanes; and their activity covers a period of about a century.<sup>2</sup> The first experiments in bibliography appear to have been made in producing catalogues of the Alexandrian libraries. Amongst other lists, two catalogues were prepared by order of Ptolemy Philadelphus, one of the tragedies, the other of the comedies contained in the collections. The *Hypoxes* of Callimachus formed a catalogue of all the principal books arranged in 120 classes. When Caesar set fire to the fleet in the harbour of Alexandria, the flames accidentally extended to the larger library of the Bruchium, and it was destroyed.<sup>3</sup> Antony endeavoured to repair the loss by presenting to Cleopatra the library from Pergamus. This was very probably placed in the Bruchium, as this continued to be the literary quarter of Alexandria until the time of Aurelian. Thenceforward the Serapeum became the principal library. The usual statement that from the date of the restoration of the Bruchium under Cleopatra the libraries continued in a flourishing condition until they were destroyed after the conquest of Alexandria by the Saracens in 640 A.D. can hardly be supported. It is very possible that one of the libraries perished when the Bruchium quarter was destroyed by Aurelian, 273 A.D. In 389 or 391 an edict of Theodosius ordered the destruction of the Serapeum, and its books were pillaged by the Christians. When we take into account the disordered condition of the times, and the neglect into which literature and science had fallen, there can be little difficulty in believing that there were but few books left to be destroyed by the soldiers of Amr. The familiar anecdote of the caliph's message to his general (vol. i. p. 494) rests mainly upon the evidence of Abulfaragius, so that we may be tempted to agree with Gibbon that the report of a stranger who wrote at the end of six hundred years is overbalanced by the silence of earlier and native annalists. It is, however, so far from easy to settle the question that a cloud of names could easily be cited upon either side, while some of the most careful inquirers confess the difficulty of a decision.<sup>4</sup>

**Pergamus.** The magnificence and renown of the libraries of the Ptolemies excited the rivalry of the kings of Pergamus, who vied with the Egyptian rulers in their encouragement of literature. Despite the obstacles presented by the embargo placed by the Ptolemies upon the export of papyrus, the library of the Attali attained considerable importance, and, as we have seen, when it was transported to Egypt numbered 200,000 volumes. We learn from a notice in Suidas that in 221 B.C. Antiochus the Great summoned the poet and grammarian Euphron of Chalcis to be his librarian.

**Rome.** The early Romans were far too warlike and practical a people to devote much attention to literature, and it is not until the last century of the republic that we hear of libraries in Rome. The collections of Carthage, which fell into their hands when Scipio sacked that city (146 B.C.), had no attractions for them; and with the exception of the writings of Mago upon agriculture, which the senate reserved for translation into Latin, they bestowed all the

books upon the kinglets of Africa.<sup>5</sup> It is in accordance with the military character of the Romans that the first considerable collections of which we hear in Rome were brought there as the spoils of war. The first of these was that brought by Æmilius Paulus from Macedonia after the conquest of Perseus (167 B.C.). The library of the conquered monarch was all that he reserved from the prizes of victory for himself and his sons, who were fond of letters. Next came the library of Apellicon the Teian, brought from Athens by Sulla (86 B.C.). This passed at his death into the hands of his son, but of its later history nothing is known. The rich stores of literature brought home by Lucullus from his eastern conquests (about 67 B.C.) were freely thrown open to his friends and to men of letters. Accordingly his library and the neighbouring walks were much resorted to, especially by Greeks. It was now becoming fashionable for rich men to furnish their libraries well, and the fashion prevailed until it became the subject of Seneca's scorn and Lucian's wit. The zeal of Cicero and Atticus in adding to their collections is well known to every reader of the classics. Tyrannion is said to have had 30,000 volumes of his own; and that M. Terentius Varro had large collections we may infer from Cicero's writing to him: "Si hortum in bibliotheca habes, nihil deerit." Not to prolong the list of private collectors, Serenus Sammonicus is said to have left to his pupil the younger Gordian no less than 62,000 volumes. Amongst the numerous projects entertained by Caesar was that of presenting Rome with public libraries, though it is doubtful whether any steps were actually taken towards its execution. The task of collecting and arranging the books was entrusted to Varro. This commission, as well as his own fondness for books, may have led Varro to write the book upon libraries of which a few words only have come down to us, preserved by a grammarian. Varro also appears to have been the first to ornament a library with the statues and busts of learned men, though the idea is sometimes attributed to Asinius Pollio. The greater honour of being the first actually to dedicate a library to the public is said by Pliny and Ovid to have fallen to Pollio, who erected a library in the Atrium Libertatis on Mount Aventine, defraying the cost from the spoils of his Illyrian campaign. The library of Pollio was followed by the public libraries established by Augustus. That emperor, who did so much for the embellishment of the city, erected two libraries, the Octavian and the Palatine. The former was founded (33 B.C.) in honour of his sister, and was placed in the Porticus Octaviae, the lower part of which served as a promenade, while the upper part contained the library. The charge of the books was committed to C. Melissus. The other library formed by Augustus was attached to the temple of Apollo on the Palatine hill, and appears from inscriptions to have consisted of two departments, a Greek and a Latin one, which seem to have been separately administered. The charge of the Palatine collections was given to Pompeius Maecr, who was succeeded by Julius Hyginus, the grammarian and friend of Ovid. The Octavian library perished in the fire which raged at Rome for three days in the reign of Titus. The Palatine was, at all events in great part, destroyed by fire in the reign of Commodus. The story that its collections were destroyed by order of Pope Gregory the Great in the 6th century is now generally rejected. The successors of Augustus, though they did not equal him in their patronage of learning, maintained the tradition of forming libraries. Tiberius, his immediate successor, established one in his splendid house on the Palatine, to which Gellius refers as the "Tiberian library," and

<sup>1</sup> This view as to the smallness of the ancient book before Callimachus has been pushed perhaps a little too far. See Theodor Birt's ingenious suggestions in *Die antike Buchwesen*, Berlin, 1882, p. 489 et seq. Birt, indeed, agrees that these large numbers must be discounted, not only on the ground of the very considerable number of duplicates in the Alexandrian libraries.

<sup>2</sup> See *Die antike Buchwesen*, p. 489.

<sup>3</sup> See *Die antike Buchwesen*, p. 489.

Pliny, *H. N.*, xviii.

Suetonius relates that he caused the writings and images of his favourite Greek poets to be placed in the public libraries. Vespasian established a library in the Temple of Peace erected after the burning of the city under Nero. Domitian restored the libraries which had been destroyed in the same conflagration, procuring books from every quarter, and even sending to Alexandria to have copies made. He is also said to have founded the Capitoline library, though others give the credit to Hadrian. The most famous and important of the imperial libraries, however, was that created by Ulpian Trajanus, known as the Ulpian library, which was first established in the Forum of Trajan, but was afterwards removed to the baths of Diocletian. In this library were deposited by Trajan the "libri lintei" and "libri elephantini," upon which the senatus consulta and other transactions relating to the emperors were written. The library of Domitian, which had been destroyed by fire in the reign of Commodus, was restored by Gordian, who added to it the books bequeathed to him by Serenus Sammonicus. Altogether in the 4th century there are said to have been twenty-eight public libraries in Rome.

Nor were public libraries confined to Rome. Besides a library at Tibur, which is twice mentioned by Gellius, and was probably founded by Hadrian, the younger Pliny mentions that he had himself dedicated a library to his fellow-townsmen at Comum; and an inscription discovered at Milan proves that he also contributed a large sum to the support of a library there. Hadrian established a library at Athens; and Strabo mentions the library of Smyrna. Gellius also mentions a library at Patrae. From one of his references (xix. 5) to the Thartine library we may infer that it was not unusual for books to be lent out from these libraries. Considerable care was bestowed by the Romans upon the placing of their libraries. The room or building generally had an eastern aspect. The books or rolls were arranged upon the shelves of presses running round the walls, with additional presses placed in the middle of the room. Thus the library discovered at Herculaneum contained 1756 MSS. placed on shelves running round the room to a height of some 6 feet, with a detached central press. These presses in large libraries were numbered. They were often made of precious woods and richly ornamented, while the room was adorned with portraits and statues.

As the number of libraries in Rome increased, the librarian, who was generally a slave or freedman, became a recognized public functionary. The names of several librarians are preserved to us in inscriptions, including that of C. Hymeneus, who appears to have fulfilled the double function of physician and librarian to Augustus. The general superintendence of the public libraries was committed to a special official. Thus from Nero to Trajan Decimus, an Alexandrian rhetorician, discharged this function. Under Hadrian it was entrusted to his former tutor C. Julius Vestinus, who afterwards became administrator of the Museum at Alexandria.

When the seat of empire was removed by Constantine to his new capital up on the Bosphorus, the emperor established a collection there in which Christian literature was probably admitted for the first time into an imperial library. Diligent search was made after the Christian books which had been doomed to destruction by Diocletian. Even at the death of Constantine, however, the number of books which had been brought together amounted only to 6900. The smallness of the number, it has been suggested, seems to show that Constantine's library was mainly intended as a repository of Christian literature. However this may be, the collection was greatly enlarged by some of Constantine's successors, especially by Julian and Theodosius, at whose

death it is said to have increased to 100,000 volumes. Julian, himself a close student and voluminous writer, though he did his best to discourage learning among the Christians, and to destroy their libraries, not only augmented the library at Constantinople, but founded others, including one at Nisibis, which was soon afterwards destroyed by fire. From the Theodosian code we learn that in the time of that emperor a staff of seven copyists was attached to the library at Constantinople under the direction of the librarian. The library was burnt under the emperor Zeno in 477, but was again restored.

Meanwhile, as Christianity made its way and a distinctively Christian literature grew up, the institution of libraries became part of the organization of the church. When the church of Jerusalem was founded in the 3d century a library was added to it, and it became the rule to attach to every church a collection of the books necessary for the inculcation of Christian doctrine. The largest of these libraries, that founded by Pamphilus at Caesarea, and said to have been increased by Eusebius, the historian of the church, to 30,000 volumes, is frequently mentioned by St Jerome. St Augustine bequeathed his collection to the library of the church at Hippo, which was fortunate enough to escape destruction at the hands of the Vandals.

The removal of the capital to Byzantium was in its result a serious blow to literature. Henceforward the science and learning of the East and West were divorced. The libraries of Rome ceased to collect the writings of the Greeks, while the Greek libraries had never cared much to collect Latin literature. The influence of the church became increasingly hostile to the study of pagan letters. The repeated invasions of the barbarians soon swept the old learning and libraries alike from the soil of Italy. With the close of the Western empire in 476 the ancient history of libraries may be said to cease.

#### MEDIEVAL PERIOD.

During the first few centuries after the fall of the Western empire, literary activity at Constantinople had fallen to its lowest ebb. In the West, amidst the general neglect of learning and literature, the collecting of books, though not wholly forgotten, was cared for by few. Sidonius Apollinaris tells us of the libraries of several private collectors in Gaul. Publius Consentius possessed a library at his villa near Narbonne which was due to the labour of three generations. The most notable of these appears to have been the prefect Tonantius Ferreolus, who had formed in his villa of Prusiana, near Nîmes, a collection which his friend playfully compares to that of Alexandria. The Goths, who had been introduced to the Scriptures in their own language by Ulfilas in the 4th century, began to pay some attention to Latin literature. Cassiodorus, the favourite minister of Theodoric, was a collector as well as an author, and on giving up the cares of government retired to a monastery which he founded in Calabria, where he employed his monks in the transcription of books.

Henceforward the charge of books as well as of education fell more and more exclusively into the hands of the church. While the old schools of the rhetoricians died out new monasteries arose everywhere. Knowledge was no longer pursued for its own sake, but became subsidiary to religious and theological teaching. The proscription of the old classical literature, which is symbolized in the fable of the destruction of the Palatine library by Gregory the Great, was only too effectual. The Gregorian tradition of opposition to pagan learning long continued to dominate the literary pursuits of the monastic orders and the labours of the scriptorium.

During the 6th and 7th centuries the learning which had been won from the Continent took refuge in the British Islands, where it was removed from the political disturbances of the mainland. In the Irish monasteries during this period there appear to have been many books, and the Venerable Bede was superior to any scholar of his age. Theodore of Tarsus brought a considerable number of books to Canterbury from Rome in the 7th century, including several Greek authors. The library of York, which was founded by Archbishop Egbert, was almost more famous than that of Canterbury. The verses are well known, in which Alcuin describes the extensive library under his charge, and the long list of authors whom he enumerates is superior to that of any other library possessed by either England or France in the 12th century, when it was unhappily burnt. The inroads of the Northmen in the 9th and 10th centuries had been fatal to the monastic libraries on both sides of the channel. It was from York that Alcuin came to Charlemagne to superintend the school attached to his palace; and it was doubtless inspired by Alcuin that Charles issued the memorable document which enjoined that in the bishoprics and monasteries within his realm care should be taken that there shall be not only a regular manner of life, but also the study of letters. When Alcuin finally retired from the court to the abbacy of Tours, there to carry out his own theory of monastic discipline and instruction, he wrote to Charles for leave to send to York for copies of the books of which they had so much need at Tours. While Alcuin thus increased the library at Tours, Charlemagne enlarged that at Fulda, which had been founded in 774, and which all through the Middle Ages stood in great respect. Lupus Servatus, a pupil of Hrabanus Maurus at Fulda, and afterwards abbot of Ferrières, was a devoted student of the classics and a great collector of books. His correspondence illustrates the difficulties which then attended the study of literature through the paucity and dearness of books, the declining care for learning, and the increasing troubles of the time. Nor were private collections of books altogether wanting during the period in which Charlemagne and his successors laboured to restore the lost traditions of liberal education and literature. Pepin le Bref had indeed met with scanty response to the request for books which he addressed to the pontiff Paul I. Charlemagne, however, collected a considerable number of choice books for his private use in two places. Although these collections were dispersed at his death, his son Louis formed a library which continued to exist under Charles the Bald. About the same time Everard, count of Friuli, formed a considerable collection which he bequeathed to a monastery. But the greatest private collector of the Middle Ages was doubtless Gerbert, Pope Sylvester II, who showed the utmost zeal and spent large sums in collecting books, not only in Rome and Italy, but from Germany, Belgium, and even from Spain.

The hopes of a revival of secular literature fell with the decline of the schools established by Charles and his successors. The knowledge of letters remained the prerogative of the church, and for the next four or five centuries the collecting and multiplication of books were almost entirely confined to the monasteries. Several of the greater orders made these an express duty; this was especially the case with the Benedictines. It was the first care of St Benedict, we are told; that in each newly founded monastery there should be a library, "et velut curia quædam illustrium auctorum." Monte Cassino became the starting point of a long line of institutions which were destined to be the centre of religion and of literature. It must indeed be remembered that literature in the sense of St Benedict meant Biblical and theological works, the lives and martyrs, and the lives and writings of

the fathers. Of the reformed Benedictine orders the Carthusians and the Cistercians were those most devoted to literary pursuits. The abbey of Fleury, of Melk, and of St Gall were remarkable for the splendour of their libraries. In a later age the labours of the congregation of St Maur form one of the most striking chapters in the history of learning. The Augustinians and the Dominicans rank next to the Benedictines in their care for literature. The libraries of St Geneviève and St Victor, belonging to the former, were amongst the largest of the monastic collections. Although their poverty might seem to put them at a disadvantage as collectors, the mendicant orders cultivated literature with much assiduity, and were closely connected with the intellectual movement to which the universities owed their rise. In England Richard of Bury praises them for their extraordinary diligence in collecting books. Sir Richard Whittington built a large library for the Grey Friars in London, and they possessed considerable libraries at Oxford.

It would be impossible to attempt here an account of all the libraries established by the monastic orders. We must be content to enumerate a few of the most eminent.

In Italy Monte Cassino is a striking example of the dangers and vicissitudes to which monastic collections were exposed. Ruined by the Lombards in the 6th century, the monastery was rebuilt and a library established to fall a prey to Saracens and to fire in the 9th. The collection then reformed survived many other chances and changes, and still exists. It affords a conspicuous example of monastic industry in the transcription, not only of theological but also of classical works. The library of Bobbio was famous for its palimpsests. The collection, of which a catalogue of the 10th century is given by Muratori,<sup>1</sup> was finally transferred to the Ambrosian library at Milan. Of the library of Pomposia, near Ravenna, Montfaucon has printed a catalogue dating from the 11th century.<sup>2</sup>

Of the monastic libraries of France the principal were those of Fleury, of Cluny, of St Riquier, and of Corbie. At Fleury Abbot Macharius in 1146 imposed a contribution for library purposes upon the officers of the community and its dependencies, an example which was followed elsewhere. After many vicissitudes, its MSS., numbering 238, were deposited in 1793 in the town library of Orleans. The library of St Riquier in the time of Louis the Pious contained 256 MSS., with over 500 works.<sup>3</sup> Of the collection at Corbie in Fleury we have also catalogues dating from the 12th and from the 17th centuries. Corbie was famous for the industry of its transcribers, and appears to have stood in active literary intercourse with other monasteries. In 1638, 406 of its choicest manuscripts were removed to St Germain-des-Prés. The remainder were removed after 1794, partly to the national library at Paris, partly to the town library of Amiens.

The chief monastic libraries of Germany were at Fulda, Corvey, Reichenau, and Sponheim. The library at Fulda owed much to Charlemagne and to its abbot Hrabanus Maurus. Under Abbot Sturmian four hundred monks were hired as copyists. In 1561 the collection numbered 774 volumes. The library of Corvey on the Weser, after being despoiled of some of its treasures in the Reformation age, was presented to the university of Marburg in 1811. It then contained 109 volumes, with 400 or 500 titles. The library of Reichenau, of which several catalogues are extant, fell a prey to fire and neglect, and its ruin was consummated by the Thirty Years' War. The library

<sup>2</sup> *Diarium Italicum*, chap. xvii.

<sup>3</sup> Catalogue printed in Edwards, *Mem. of Libraries*, i. 297-301.

of Sponheim owes its great renown to John Trithem, who was abbot at the close of the 15th century. He found it reduced to 10 volumes, and left it with upwards of 2000 at his retirement. The library at St Gall, formed as early as 816 by Gozbert, its second abbot, still exists.

England. In England the principal collections were those of Canterbury, York, Wearmouth, Whitby, Glastonbury, Croyland, Peterborough, and Durham. Of the library of the monastery of Christ Church, Canterbury, originally founded by Augustine and Theodore, and restored by Lanfranc and Anselm, a catalogue has been preserved dating from the 13th or 14th century, and containing 698 volumes, with about 3000 works. Becket Biscop, the first abbot of Wearmouth, made five journeys to Rome, and on each occasion returned with a store of books for the library. It was destroyed by the Danes about 867. Of the library at Whitby there is a catalogue dating from the 12th century. The catalogue of Glastonbury has also been printed.<sup>1</sup> When the library of Croyland perished by fire in 1091 it contained about 700 volumes. The library at Peterborough was also rich; from a catalogue of about the end of the 11th century it had 344 volumes, with nearly 1700 titles. The catalogues of the library at the monastery of Durham have been printed by the Surtees Society, and form an interesting series.

These catalogues with many others<sup>2</sup> afford abundant evidence of the limited character of the monkish collections, whether we look at the number of their volumes or at the nature of their contents. We must remember that the beliefs and discipline imposed upon the monk hardly allowed of his caring for literature for its own sake; we must also remember that the transcription of manuscripts so industriously pursued in the monasteries was a mechanical employment. The scriptoria were manufactories of books and not centres of learning. Indeed the very pains bestowed upon carefulness and neatness of transcription, and especially upon the illustrating and ornamenting of the more beautiful manuscripts, were little calculated to divert the attention of the monks from the vehicle to the thought which it expressed. The pride taken by so many communities in the richness and splendour of their libraries was often doubtless the pride of the collector and not of the scholar. That in spite of the labours of so many transcribers the costliness and scarcity of books remained so great may have been partly, but cannot have been wholly, due to the scarcity of writing materials. It may be suspected that indolence and carelessness were the rule in most monasteries, and that but few of the monks keenly realized the whole force of the sentiment expressed by one of their number in the 12th century—"Clausum sine armario quasi castrum sine armamentario." Nevertheless it must be admitted that to the labours of the monkish transcribers we are indebted for the preservation of Latin literature.

Arabians. The first conquests of the Arabians, as we have already seen, threatened hostility to literature. But, as soon as their conquests were secured, the caliphs became the patrons of learning and science. Greek manuscripts were eagerly sought for and translated into Arabic, and colleges and libraries everywhere arose. Baghdad in the East and Cordova in the West became the seats of a rich development of letters and science during the age when the civilization

of Europe was most obscured. Cairo and Tripoli were also distinguished for their libraries. The royal library of the Fatimites in Africa is said to have numbered 100,000 manuscripts, while that collected by the Omayyads of Spain is reported to have contained six times as many. It is said that there were no less than seventy libraries opened in the cities of Andalusia. Whether these figures be exaggerated or not—and they are much below those given by some Arabian writers, which are undoubtedly so—it is certain that the libraries of the Arabians and the Moors of Spain offer a very remarkable contrast to those of the Christian nations during the same period.<sup>3</sup>

The literary and scientific activity of the Arabians appears to have been the cause of a revival of letters amongst the Greeks of the Byzantine empire in the 9th century. Under Leo the Philosopher and Constantine Porphyrogenitus the libraries of Constantinople awoke into renewed life. The compilations of such writers as Stobæus, Photius, and Suidas, as well as the labours of innumerable critics and commentators, bear witness to the activity, if not to the lofty character of the pursuits, of the Byzantine scholars. The labours of transcription were industriously pursued in the libraries and in the monasteries of Mount Athos and the Aegean, and it was from these quarters that the restorers of learning brought into Italy so many Greek manuscripts. In this way many of the treasures of ancient literature had been already conveyed to the West before the fate which overtook the libraries of Constantinople on the fall of the city in 1453. Renaissance.

Meanwhile in the West, with the reviving interest in literature which already marks the 14th century, we find arising outside the monasteries a taste for collecting books. St Louis of France and his successors had formed small collections, none of which survived its possessor. It was reserved for Charles V. to form a considerable library which he intended to be permanent. In 1373 he had amassed 910 volumes, and had a catalogue of them prepared, from which we see that it included a good deal of the new literature. In our own country Guy, earl of Warwick, formed a curious collection of French romances, which he bequeathed to Bordesley Abbey on his death in 1315. Richard d'Aungervyle of Bury, the author of the *Philobiblon*, amassed a noble collection of books, and had special opportunities of doing so as Edward III.'s chancellor and ambassador. He founded Durham College at Oxford, and equipped it with a library a hundred years before Humphrey, duke of Gloucester, made his benefaction of books to the university. The taste for secular literature, and the enthusiasm for the ancient classics, gave a fresh direction to the researches of collectors. A disposition to encourage literature began to show itself amongst the great. This was most notable amongst the Italian princes. Cosimo de' Medici formed a library at Venice while living there in exile in 1433, and on his return to Florence laid the foundation of the great Medicean library. The honour of establishing the first modern public library in Italy had been already secured by Niccolò Niccoli, who left his library of over 800 volumes for the use of the public on his death in 1436. Frederick, duke of Urbino, collected all the writings in Greek and Latin which he could procure, and we have an interesting account of his collection written by his first librarian, Vespasiano. The ardour for classical studies led to those active researches for the Latin writers who were buried in the monastic libraries which are especially identified with the name of Poggio. For some time before the fall of that capital, the perilous state

<sup>1</sup> By Heine in the edition of John of Glastonbury.

<sup>2</sup> Many such catalogues may be found in the collections of D'Achery, Martene and Durand, &c. 1757, and in the bibliographical periodicals of Naumann and Pertz &c. The Rev. Joseph Hunter has collected some particulars as to the contents of the English monastic libraries, and Mr Edwards has printed a list of the catalogues known to exist (*Libraries and Founders of Libraries*, 1865, pp. 418-54). There are said to be over six hundred such catalogues in the Royal Library at Munich.

<sup>3</sup> Among the Arabs, however, as among the Christians, theological bigotry did not always approve of non-theological literature, and the great library of Cordova was sacrificed by Almanzor to his reputation for orthodoxy, 978 A.D.

of the Eastern empire had driven many Greek scholars from Constantinople into western Europe, where they had directed the studies and formed the taste of the zealous students of the Greek language and literature. The enthusiasm of the Italian princes extended itself beyond the Alps. Matthias Corvinus, king of Hungary, amassed a collection of splendidly executed and magnificently bound manuscripts, which at his death are said to have reached the almost incredible number of 50,000 volumes. The library was not destined long to survive its founder. There is reason to believe that it had been very seriously despoiled even before it perished at the hands of the Turks on the fall of Buda in 1527. A few of its treasures are still preserved in some of the libraries of Europe. While these munificent patrons of learning were thus taking pains to recover and multiply the treasures of ancient literature by the patient labour of transcribers and calligraphers, an art was being elaborated which was destined to revolutionize the whole condition of literature and libraries. With the invention of printing, so happily coinciding with the revival of true learning and sound science, the modern history of libraries may be said to begin.

#### MODERN LIBRARIES.

These are most conveniently described in geographical order, and a general survey on this method will be found in the tables at the end of this article. The following sketch supplies additional details.

##### *The United Kingdom.*

**British Museum.** The British Museum ranks in importance before all the great libraries of the world, with the single exception of the Bibliothèque Nationale at Paris, and far excels the latter institution in the systematic arrangement and accessibility of its contents. Recent changes have somewhat limited its former universality of character, but it still remains the grand national repository of literature and archaeology. The library consists of over 1,550,000 printed volumes and 50,000 manuscripts. This extraordinary opulence is principally due to the enlightened energy of the late Sir Antonio Panizzi. The number of volumes in the printed book department, when he took the keepership in 1837, was only 240,000; and during the nineteen years he held that office about 100,000 were added, mostly by purchase, under his advice and direction. It was Panizzi likewise who first seriously set to work to see that the national library reaped all the benefits bestowed upon it by the Copyright Act.

The foundation of the British Museum dates from 1753, when effect was given to the bequest (in exchange for £20,000 to be paid to his executors) by Sir Hans Sloane, of his books, manuscripts, curiosities, &c., to be held by trustees for the use of the nation. A bill was passed through parliament for the purchase of the Sloane collections and of the Harleian MSS., costing £10,000. To these, with the Cottonian MSS., acquired by the country in 1700, was added by George II., in 1757, the royal library of the former kings of England, coupled with the privilege, which that library had for many years enjoyed, of obtaining a copy of every publication entered at Stationers' Hall. This addition was of the highest importance, as it enriched the museum with the old collections of Archbishop Cranmer, Henry prince of Wales, and other patrons of literature, while the transfer of the privilege with regard to the acquisition of new books, a right which has been maintained by successive Copyright Acts, secured a large and continuous augmentation, the yearly average of which has now reached 8000 or 9000 volumes. A lottery having

been authorized to defray the expenses of purchases, as well as for providing suitable accommodation, the museum and library were established in Montague House, and opened to the public 15th January 1759. In 1763 George III. presented the well-known Thomason collection (in 2220 volumes) of books and pamphlets issued in England between 1640 and 1662, embracing all the controversial literature which appeared during that period. The Rev. C. M. Cracherode, one of the trustees, bequeathed his collection of choice books in 1799, and in 1820 Sir Joseph Banks left to the nation his important library of 16,000 volumes. Many other libraries have since then been incorporated in the museum, the valuable being George III.'s royal collection (15,000 volumes of tracts, and 65,259 volumes of printed books, many of the utmost rarity, which had cost the king about £130,000), which was presented (for a pecuniary gratification, it has been said) by George IV. in 1823, and the Right Honourable Thomas Grenville (20,000 volumes of rare books, all in fine condition and handsomely bound) required under bequest in 1846. The Cracherode, Banksian, Kings, and Grenville libraries are still preserved in their original collections. Other libraries of minor importance have been absorbed in a similar way, while, at the same time, of Panizzi, no opportunity has been neglected of making useful purchases at all the British and Continental book auctions.

The collection of English books is far from approaching completeness, but, apart from the enormous number of volumes, the library contains an extraordinary quantity of rarities. Few libraries in the United States equal either in number or value the American books in the museum. The collection of Slavonic literature, due to the initiative of the late Mr Watts, is a remarkable addition to that of the St Petersburg Imperial Library; it is believed to be the largest in existence. Indeed, in cosmopolitan literature the museum is without a rival in the world, perhaps as it does the best Hungarian collection out of that country, the best Dutch library out of Holland, and in short the best library in any European language out of the territory in which the language is vernacular. The Hebrew books number over 12,000, the Chinese nearly 10,000, and the printed books in other Oriental languages about 13,000 volumes. Periodical literature has not been neglected, and the series of newspapers is of great interest. Great pains are taken by the authorities to obtain the copies of the newspapers published in the United Kingdom to which they are entitled by the provisions of the Copyright Act, and upwards of 1900 are annually collected, filed, and bound. Under the English Copyright Act, such were received, in 1881, no counting single pieces, such as broadsides, songs, &c., 887 volumes and pamphlets and 21,792 parts of volumes, a total of 22,679. The international copyright treaties 941 volumes and 10,000 parts.

The department of MSS. is equal in importance to that of the printed book. The collection of MSS. in European languages ranges from the 12th century before Christ down to our own times and includes the ALEXANDRIAN MS. (c. 400). The old historical chronicle of England, the charters of the Anglo-Saxon kings, the celebrated series of Arthurian romances are well represented, and care has been taken to acquire on every available opportunity the unprinted works of English writers. The famous collections of MSS. made by Sir Robert Cotton, and Henry earl of Oxford, have already been mentioned, and in addition to these and other sources the museum has become rich in early Anglo-Saxon and Latin codices, some of the most striking marvels of skill in calligraphy and ornamentation, such as the charters of King Edgar and Henry I. to Hyde Abbey, which were written in gold letters, other interesting for different reasons, such as the book of Durham, in Latin and Anglo-

Saxon, reputed to have been Bede's own copy. The Burney collection of classical MSS. furnished important additions, so that from this source and from the collection of Arundel MSS. (transferred from the Royal Society in 1831); the museum can boast of an early copy of the *Iliad*, and one of the earliest known codices of the *Odyssey*. There is likewise an extensive series of ancient Irish texts, with many modern transcripts, the Bridgewater MSS. on French history, and Lord Guilford's singular collection to illustrate the history of Italy. Special reference may be made to the celebrated Bedford Missal, illuminated for the duke of Bedford, regent of France, and to Henry VI.'s copy of Hardyng's chronicle. The Oriental collection is also extremely rich and ample, including the library formed by Mr Rich (consul at Baghdad in the early part of this century), and a vast quantity of Arabic, Persian, and Turkish MSS.; the Chambers collection of Sanskrit MSS.; several other collections of Indian MSS.; and a copious library of Hebrew MSS. (including that of the great scholar Michaelis, and codices of great age, recently brought from Yemen). The collection of Syriac MSS., embracing the relics of the famous library of the convent of St Mary Deipara in the Nitrian desert, formed by the abbot Moses of Nisibis, in the 10th century, is the most important in existence; of the large store of Abyssinian volumes many were amassed after the campaign against King Theodore. The number of genealogical rolls and documents relating to the local and family history of Great Britain is very large. Altogether there are now over 50,000 MSS. (of which 8500 are Oriental), besides 15,000 charters and rolls.

The musical works comprise upwards of 11,000 volumes of vocal and nearly 6000 volumes of instrumental music, the number of separate pieces amounting to more than 70,000. The catalogue is in manuscript. The collection of maps, charts, plans, and topographical drawings is also a remarkable one. The maps are nearly 116,000 in number. Letter A of a printed catalogue of the maps is already in type.

The name of Panizzi is inseparably connected with his circular reading room, opened in 1857. This is encompassed by the new library, with shelf-space for a million and a half volumes. The presses inside the reading room, arranged in three tiers, contain upwards of 80,000 volumes, those on the top and floor (20,000) being books of reference to which readers have unlimited access. The comfortable accommodation for readers is briefly described below. Perhaps not the least convenient arrangement it here is the presence of the superintendent, whose duty it is to help readers in their difficulties; the varied qualifications of the present holder of the office are well known. The circular light has been successfully used until 8 o'clock P.M. through the darker months from the earlier part of October. In order to enjoy the privilege of reading at the British Museum, the applicant (who must be twenty-one years of age) must obtain a renewable ticket of admission through a recommendation from a household address to the principal librarian. Formerly no person was admitted until the ticket had been presented at the entrance, but latterly this rule has been considerably relaxed. During 1881 the number of readers was 13,542. In spite of the system to which it has sometimes been subjected, it is evident that the general catalogue of the printed books (consisting of upwards of 2000 volumes in manuscript) is a most valuable and interesting work in a praiseworthy manner. Some slight defect of the catalogue may be derived from the fact that it contains the names of over 2100 authors of the name of Smith. But the rapidly increasing size of the catalogue has imposed on the printer the necessity of resorting to print in order to finish the bulk. Since 1859 the titles of all accessions have been printed, and as it becomes necessary to break the manuscript volumes, the titles contained in them are also printed; in course of time, therefore, the whole of the titles will have been put into type. The sheets are published at regular intervals, and can be purchased. It is proposed to issue separate holdings of special interest, whether of subjects or of authors, e.g. Shakespeare, Bible, Liturgies, &c. Considerable progress has been made in the preparation for the press of a catalogue of English books printed before the year 1640.

The printed catalogues of books commence with one published in 2 vols. folio, 1787, followed by that of 1813-19 in 7 vols. 8vo; the next is that of the library of George III., 1820-29, 5 vols. folio, with

2 vols. 8vo, 1834, describing the geographical and topographical collections; and then the *Bibliotheca Grenvilliana*, 1842-72, 4 vols. 8vo. The first vol. (letter A) of a general catalogue appeared in 1841 in a folio volume which has never been added to. The octavo catalogue of the Hebrew books came out in 1867; that of the Sanskrit and Pali literature is in 4to, 1876; and the Chinese catalogue is also in 4to, 1877. There are also printed lists of the books of reference (1871) and bibliographies (1881) in the reading-room. Private enterprise has done a great deal towards cataloguing the American books (by Mr H. Stevens, 4 vols. 8vo), and the British topographical literature has recently been the subject of a similar publication by Mr J. P. Anderson, 8vo, 1881.

The printed catalogues of the MSS. are—that of the old Royal Library, 1734, 4to; the Sloane and others hitherto undescribed, 1782, 2 vols. 4to; the Cottonian, 1802, folio; the Harleian, 1808, 4 vols. folio; the Hargrave, 1818, 4to; the Lansdowne, 1819, folio; the Arundel, 1840, folio; the Burney, 1840, folio; the Oriental (Arabic and Ethiopic), 5 pts., folio, 1838-71; the Syriac, 1870-73, 3 pts., 4to; the Ethiopic, 1877, 4to; the Persian, 1879-80, 2 vols. 4to; and the Spanish, 1875-80, 3 vols. 8vo. There are also catalogues of the Greek and Egyptian papyri, 1839-46, 5 pts., folio. The additional MSS. from 1831-75 are described in 10 vols. 8vo, 1835-77, with indexes (1783-1835) in folio and (1854-75) in 8vo. A catalogue of the MS. music was produced in 1842, 8vo; and one of the MS. maps in 1844, 2 vols. 8vo.

The binding is done upon the premises, and the sum expended each year is £9000. The average sum annually spent upon the purchase of books is about £10,000, and upon MSS. £2500. Since the catalogues ceased to be transcribed £8000 is annually spent on printing.

London is very badly off as regards public libraries, and the largest general collection which is available without any tedious preliminary forms is that of the corporation of the city of London at the Guildhall. A library was established here by Sir Richard Whittington between 1421-26, and several notices in the civic records show how well in those times the citizens cared for their books. But it did not remain without accident; in 1522 the Lord Protector Somerset carried off three cart-loads of books, and during the great fire of 1666 the remainder was destroyed together with the library buildings. Nothing was done to repair the loss until 1824, when a committee was appointed, and rooms set apart for library purposes. In 1840 a catalogue of 10,000 volumes was printed, and in 1859 a second was prepared of 40,000 volumes. In consequence of the large and increasing number of the readers, the present fine building was commenced about ten years later, and, after having cost £90,000, was opened in 1873 as a free public library. There are now upwards of 80,000 printed volumes and 300 MSS. The contents are of a general character, and include a special collection of books about London, the Solomons Hebrew and rabbinical library, and the libraries of the Clockmakers' Company and the old Dutch church in Austin Friars. The only rate-supported library in the metropolis is that of the united parishes of St Margaret and St John at Westminster (13,527 volumes), founded in 1857, principally by the influence of the late Lord Hatherley, with a small branch at Knightsbridge. The Notting Hill Free Public Library (6000 volumes) is supported by Mr James Heywood, and the Bethnal Green Free Library and South London Free Library by voluntary subscriptions.

Of libraries of a more special character, those principally devoted to theology have perhaps the first claim to notice. The archiepiscopal library at Lambeth was founded in 1610 by Archbishop Bancroft, and has been enriched by the gifts of Laud, Tenison, Manners-Sutton, and others of his successors; it is now lodged in the noble hall built by Juxon. The treasures consist of the illuminated MSS., and a rich store of early printed books; of the latter two catalogues have been issued by S. R. Maitland. The MSS. are described in H. J. Todd's catalogue, 1812. Sion College is a guild of the parochial clergy of the city and suburbs of London, and the library was founded in 1629 for their use; laymen may also read (but not borrow) the

books when recommended by some beneficed metropolitan clergyman. The library is especially rich in liturgies, Port-Royal authors, pamphlets, &c. The copyright privilege was commuted in 1835 for an annual sum of £363, 15s. 2d. The present building was erected immediately after the great fire. The chamber in the old cloisters, in which the library of the dean and chapter of Westminster is preserved, is well known from the charming description by Washington Irving in his *Sketch Book*. There are about 11,000 volumes, mostly of old theology and history, including many rare Bibles and other valuable books. The library of the dean and chapter of St Paul's was founded in very early times, and now numbers some 8700 volumes, mainly theological, besides over 10,300 pamphlets, with a good collection of early Bibles and Testaments, Paul's Cross Sermons, and works connected with the cathedral. Dr Williams's library was founded by the will of an eminent Presbyterian divine of that name; it was opened in 1729. The books (30,000 printed volumes and 1000 MSS.) are housed in a new building, completed in 1873. Theology of all schools of opinion is represented, and there are special collections of theosophical books and MSS., the works of Boehme, Law, and other mystical writers. The MSS. include the original minutes of the Westminster Assembly, letters and treatises of Richard Baxter, &c. The British and Foreign Bible Society has a remarkable collection of Bibles and Biblical literature, of which a printed catalogue was published in 1855. Perhaps the best library of Catholic theology in London is that of the Oratory at South Kensington, established in 1849.

Of the law libraries, that at Lincoln's Inn is the oldest and the largest. It dates from 1197, when John Nethersale, a member of the society, made a bequest of forty marks, part of which was to be devoted to the building of a library for the benefit of the students of the laws of England. A catalogue of the printed books was published in 1859, and the MSS. were catalogued by the Rev. Joseph Hunter in 1837. The library of the Inner Temple is known to have existed in 1540. In the middle of the 17th century it received a considerable benefaction from William Petyt, the well-known keeper of the Tower records. There are now about 36,000 volumes, including the pamphlets collected by John Adolphus for his *History of England*, books on crime and prisons brought together by Mr Crawford, and a selection of works on jurisprudence made by John Austin. A library in connexion with the Middle Temple was in existence during the reign of Henry VIII., but the date usually assigned to its foundation is 1641, when Robert Ashley left his books to the inn of which he had been a member. Gray's Inn Library was perhaps established before 1555. In 1669 was made the first catalogue of the books, and the next, still extant, in 1689. The Incorporated Law Society (1831) has a good law and general library (30,000 volumes), including the best collection of private Acts of Parliament in England, and a large number of pamphlets relating to Anglo-Catholic controversies brought together by the late Rev. Joseph Mendham. The catalogue was printed in 1869.

The collegiate library at Dulwich dates from 1619, and a list of its earliest accessions, in the handwriting of the founder, may still be seen. There are now about 7000 volumes of miscellaneous works of the 17th and 18th centuries, with a few rare books. A catalogue of them was printed in 1880, and one describing the MSS. (567) and the manuscripts (606) was issued during the succeeding year. The last two classes are very important, and include the well-known "Alleyn Papers" and the theatrical diary of Philip Henslow. Soon after the foundation of the University of London in 1837, an endeavour was made to provide a library, but it has had to look to gifts rather

than to purchases for its accessions. In 1871 the university obtained, in this manner, the library of the historian Grote, and in the same year Lord Overstone purchased and presented the mathematical collection of De Morgan. A catalogue was printed in 1875. The books at University College (1828) are much more numerous, and here also a considerable proportion are donations, including the Morrison Chinese library of 10,000 volumes, the Daulby-Roscoe Icelandic books, the Graves mathematical and physical library, and the Enlow Dante bequest. A printed catalogue of the greater portion was brought out in 1879. The library at King's College includes a collection of works on Eastern subjects bequeathed by Dr Marsden, as well as the scientific books formerly belonging to Sir Charles Wheatstone. The medical library is distinct. The educational library at the South Kensington Museum numbers about 12,200 volumes, and may be consulted by teachers and students of the departmental schools, and by other persons on the same terms as the art library mentioned below. The ninth edition of the catalogue appeared in 1876.

The library of the Patent Office is the largest scientific and technical collection, indeed the only one which is readily open to the public. There are at present 60,000 volumes, including a very extensive set of the transactions and journals of learned bodies. A catalogue is now in the press. Transaction and proceedings of societies, with scientific periodicals, comprise almost the whole library of the Royal Society, which extend to about 40,000 volumes. The ducal Evelyn bequest of the seventh duke of Norfolk to present to the Society the Arundel library, part of which had formerly belonged to Martham Corvinus. The MSS., however, were sold to the British Museum in 1831 for £3559, and a quantity of rare printed books have also been disposed of. Scientific inquirers are freely admitted to the Museum of Practical Geology in Jernyn Street, where there are over 20,000 volumes on geology, mineralogy, and natural history, including the former collections of De La Beche and Marchison. A printed catalogue was issued in 1878. For the libraries of other scientific institutions see the table.

Medical and surgical libraries are attached to all the chief hospitals and medical societies (see the table).

For the fine arts there is the National Art Library (1852) at the South Kensington Museum, which is now an excellent collection of 56,000 volumes, 26,000 photographs, 25,000 drawings, and 80,000 prints. Art objects are admitted free, as are ordinary visitors on Museum pay days; otherwise a charge of 6d. per week is made to the lender. The library of the Royal Academy of Arts, at its journey from Somerset House to Trafalgar Square, has been lodged in the old ball room of Burlington House since 1875. At the National Gallery is preserved for official use the library (3500 volumes) formerly belonging to Sir C. L. Eastlake, P.R.A., which is particularly rich in catalogues and descriptions of picture galleries. The Royal Institution of British Architects (1834) possesses over 6500 volumes on architectural and allied subjects, including an almost complete collection of editions of Vitruvius. The library of the Royal Academy of Music (1870) is almost exclusively musical, and, although numbering less than 1000 volumes, contains many rare and interesting works. The library of the Sacred Harmonic Society is said to be one of the best arranged and most valuable musical collections in England. A third edition of the printed catalogue appeared in 1872, when the library contained 4851 volumes.<sup>1</sup>

<sup>1</sup> For a very complete account of the chief public and private musical collections both at home and abroad, see the article "Musical Libraries," in Dr Grove's *Dictionary of Music*, ii. 417.

The best library of archaeology and kindred subjects is that of the Society of Antiquaries, consisting of nearly 20,000 printed volumes and 500 MSS. It is rich in early printed books, topography, heraldry, and numismatics, and includes a curious collection of books on pageants presented by Mr Fairholt, and the remarkable assemblage of lexicographical works formerly belonging to the late Albert Way, given by his widow. There is a good muster of heraldic works at the Herald's College, and the library of Sir John Soane (15,000 volumes) is still preserved in the museum at his house in Lincoln's Inn Fields. The printed catalogue (1878) shows that it is a fairly good collection of books on architecture and antiquities.

Among subscription libraries, the London Library stands first in order of importance. It was founded in 1841 as a lending library for the use of scholars, and Dean Milman, Sir G. C. Lewis, Mr Gladstone, Thomas Carlyle, Henry Hallam, and other eminent men took part in its formation. By means of a moderate subscription, funds were raised for the purchase of books on general subjects, which now amount to about 90,000 volumes. The latest catalogue was printed in 1875, with a supplement in 1881. The London Institution (1805) is a proprietary library to which proprietor's nominees and yearly subscribers also have admission. For reference purposes reader's tickets are very liberally granted to other persons. The books now number about 70,000 volumes in general literature; the departments of history and topography are especially rich, and the number is rapidly growing. A complete catalogue was published in 1837-43; almost the whole collection, including reference and circulating libraries very minutely classified, is contained in one room. Porson filled the position of librarian here at the close of his life, but he proved no better a librarian than did Casaubon before him at Paris. The library of the Royal Institution of Great Britain was founded in 1803 by the subscriptions of the members, amounting, in 1806, to £6000. There are now 40,000 volumes in scientific and general literature; they are not lent out. There is an interesting series of 56 volumes of MS. correspondence relating to the American war.

The libraries of the two branches of the legislature may be named with those of the great public offices. The Foreign Office library contains about 70,000 volumes, including the old library of the Board of Trade (20,000 volumes); history, geography, and law are well represented, and the department of treaties and diplomacy is of course very complete. The India Office library was formed by a vote of the court of directors of the East India Company in 1801. The services in India were also invited to aid in the creation of an institution which should become a permanent repository of Oriental lore, and many munificent donations were received in consequence of the appeal. The printed books now number nearly 40,000, chiefly on Indian and Oriental subjects, with about 10,000 Sanskrit, Arabic, Persian, Pali, and other Oriental manuscripts. Loth's excellent catalogue of the Arabic codices was published in 1877, and other catalogues are now ready for the press. At the Colonial Office there is a collection of about 12,000 works relating to colonial history and administration, and the Home Office possesses about 5000 volumes of parliamentary, historical, and legal works. The Admiralty library extends to about 25,000 volumes, chiefly voyages and travels; a printed catalogue was issued in 1875. At the War Office there are also 25,000 volumes, mainly topographical and military. The MS. records are estimated to extend to 100,000 volumes, but only those of the last twenty years are kept in Pall Mall, the remainder being at the Record Office. These records extend from the time of Queen Elizabeth, and there are some of earlier date. The older volumes belonged to the late Board of Ordnance,

and the series also includes the despatches from generals commanding armies on foreign service. All these libraries are for official use only, but at the India Office strangers are admitted upon proper introduction.

Many of the principal clubs possess libraries; that of the Athenæum is by far the most important. It now numbers about 48,000 volumes of books in all departments of literature, and is especially rich in well-bound and fine copies of works on the fine arts, archaeology, topography, and history. The pamphlets, of which there is a complete printed catalogue, as well as of the books, form a remarkable series, including those collected by Gibbon and Mackintosh. Next comes the Reform Club, with about 30,000 volumes, chiefly in belles-lettres, with a fair proportion of parliamentary and historical works. The Oxford and Cambridge Club has 20,000 volumes in general and classical literature. At the Garrick there is a small dramatic collection; and the United Service Club, besides a number of books on professional subjects, possesses the fine library which formerly belonged to Dugald Stewart.

A few libraries which could not be brought into any of the foregoing classes may now be spoken of. First comes the library of the Royal Geographical Society (1832), a valuable collection of 20,000 volumes of voyages and travels, and works on the sciences connected with geography, with many costly Government publications and geographical serials. The catalogue has been printed with supplements down to 1880. The maps and charts number 35,000, with 500 atlases and 240 large diagrams. Since 1854, in consideration of an annual grant of £500 from the treasury, the map room has been open for public reference. At the Royal United Service Institution there are also about 20,000 volumes, chiefly naval and military, with a printed catalogue, 1865. Besides the members, officers of both services are admitted. The Royal Asiatic Society has a library of nearly 8000 printed books, with 750 MSS. in Sanskrit, Persian, Turkish, &c., 5000 Chinese books, and 220 Japanese. Besides the art and educational libraries at South Kensington, there are also deposited at the museum, and open under the same regulations, the library of the Rev. Alexander Dyce, bequeathed in 1869, and the books of John Forster, left in 1876. The Dyce collection (15,000 volumes) is strong in the English drama and poetry, Italian literature, and classical authors. The Forster library (19,000 volumes) abounds in history, biography, travels, plays, and fiction, tracts, Americana, proclamations, ballads, &c.; the manuscripts include three note-books of Leonardo da Vinci, and the Garrick correspondence in 39 volumes.

Notices of a considerable number of other metropolitan libraries, not mentioned in the preceding pages, may be found in the tables at the end of this article.

With one or two exceptions, libraries are attached to the cathedrals of England and Wales. Though they are of course intended for the use of the cathedral or diocesan clergy, they are in most cases open to any respectable person who may be properly introduced. They seldom contain very much modern literature, chiefly consisting of older theology, with more or less addition of classical and historical literature. They vary in extent from a few volumes, as at Llandaff or St David's, to 15,000 volumes, as at Durham. Together they possess nearly 150,000 printed and manuscript volumes. As a rule, very little is spent upon them, and they are very little used.

The library of Christ Church, Oxford, belongs alike to the college and the cathedral, but will be more properly described as a college library. The cathedral library at Durham dates from monastic times, and possesses many of the books which belonged to the monastery. These were added to by Dean Sudbury, the second founder of the library, and Bishop Cosin. The collection has been considerably increased in more modern times, and now contains

15,000 volumes. It is especially rich in MSS., some of which are of great beauty and value; a catalogue of them was printed in 1825. The library has good topographical and entomological collections. The chapter spend £370 per annum in salaries and in books. The library at York numbers about 11,000 volumes, and has been very liberally thrown open to the public. It is kept in the former chapel of the archbishop's palace, and has many valuable MSS. and early printed books. The foundation of the library at Canterbury dates probably from the Roman mission to England, 598 A.D., although the library does not retain any of the books then brought over, or even of the books said to have been sent by Pope Gregory to the first archbishop in 601. It is recorded that among Lanfranc's buildings was a new library, and Becket is said to have collected books abroad to present to the library. The collection now numbers about 9900 printed books, with about 110 MS. volumes, and between 6000 and 7000 documents. A catalogue was printed in 1802. The present building was erected in 1867 on part of the site of the monastic dormitory. The library at Lincoln contains 7400 volumes, of which a catalogue was printed in 1859. It possesses a fine collection of political tracts of the age of Elizabeth, James, and Charles I. The present collection at Chichester dates from the Restoration only; that at Ely is rich in books and tracts relating to the non-jurors. The library at Exeter possesses many Saxon MSS. of extreme interest, one of them being the gift of Leofric, the first bishop. The treasures of Lichfield were destroyed by the Puritans during the civil war, and the existing library is of later formation. Frances, duchess of Somerset, bequeathed to it nearly 1000 volumes, including the famous *Exangeliary* of St Chad. The collection at Norwich is chiefly modern, and was presented by Dr Sayers. The earlier library at Peterborough having almost wholly perished in the civil war, Bishop White Kennett became the virtual founder of the present collection. Salisbury is rich in incunabula, and a catalogue has recently been printed. Winchester Cathedral Library is mainly the bequest of Bishop Morley in the 17th century. The library at Bristol, then numbering 6000 or 7000 volumes, was burnt and pillaged by the mob in the riots of 1831. Only about 1000 volumes were saved, many of which were recovered, but few additions have been made to them. At Chester in 1691 Dean Arderne bequeathed his books and part of his estate "as the beginning of a public library for the clergy and city." The library of Hereford is a good specimen of an old monastic library; the books are placed in the Lady Chapel, and about 230 choice MSS. are chained to oaken desks. The books are ranged with the edges outwards upon open shelves, to which they are attached by chains and bars. The four Welsh cathedrals were supplied with libraries by a deed of settlement in 1709. The largest of them, that of St Asaph, has about 1750 volumes.

Oxford.

The Bodleian Library; though it had been preceded by various efforts towards a university library, owed its origin to Sir Thomas Bodley. After a long and honourable career as a diplomatist he determined, as he says, to take his farewell of state employments, and concluded to set up his staff at the library door in Oxon. Contributing largely himself, and procuring contributions from others, he opened the library with upwards of 2000 volumes in 1602. In 1610 he obtained a grant from the Stationers' Company of a copy of every work printed in the country. The additions made to the library soon surpassed the capacity of the room, and the founder proceeded to enlarge it. By his will he left considerable property to the university for the maintenance and increase of the library. The example set by Bodley found many noble imitators. Amongst the chief benefactors have been Sir Henry Savile, Archbishop Laud, John Selden, Sir Kenelm Digby, Lord Fairfax, Richard Gough, Francis Douce, Richard Rawlinson, Rev. Robert Mason, and F. W. Hope. The library now contains almost 400,000 printed volumes, and about 30,000 manuscripts. The number of separate works exceeds a million. But the number of volumes conveys a very inadequate idea of the valuable character of the collection. In the department of Oriental manuscripts it is perhaps superior to any other European library; and it is exceedingly rich in other manuscript treasures. It possesses a splendid series of Greek and Latin *editiones principes*, and of the earliest productions of English presses. Its historical manuscripts contain most valuable materials for the general and literary history of the country.

The last general catalogue of the printed books was printed in 4 vols. folio, 1843-51. In 1859 it was decided to prepare a new

manuscript catalogue on the plan of the great catalogue at the British Museum, and this has recently been completed in duplicate. It extends to over 700 folio volumes, in which the books are entered on manifolded slips. It is an alphabetical author-catalogue; and the Bodleian, like the British Museum, has no accessible subject index. A catalogue on subjects is now, however, in course of preparation. There are also printed catalogues of the books belonging to several of the separate collections. The MSS. are in general catalogued according to the collections to which they belong, and they are all indexed, although they are not all catalogued as yet. Five volumes have been published under the late Mr Cox's editorship of the "Catalogi Codicum MSS. Bibliothecae Bodleianae," 1833-63, in quarto, and there is a fourth catalogue of Oriental MSS.

In 1860 the beautiful building known as the "Radcliffe Library," now called the "Camera Bodleiana," was offered to the curators of the Bodleian by the Radcliffe trustees. It is used as a storehouse for the more modern books, including the new periodicals, which lie upon its tall "and it also serves as a reading-room. It is the only room open after the hour when the older building is closed, owing to the rule as to the exclusion of artificial light. The separation of the books is a source of some inconvenience in practice, and it has been proposed of late years to remove the entire collections to a new building which should be erected for the purpose of accommodating them.

The library is open by right to all university, and to others (over eighteen years of age) upon producing a satisfactory recommendation. No book is sent out of the library except by special leave, in which respect there is a marked contrast with the University Library at Cambridge, and still more with the University Library at London. The hours are from 9 to 4 and 9 to 3, according to the time of year, the Camera being open from 10 to 6 for all the year round. The library is closed on all working days in the year. The general committee to a board of thirteen members, most of whom are honorary, is comparatively small; the more important members of the library are the members of the Senate, and the members of the University. The library is situated in the centre of the city, and is easily accessible.

The other important collections are the Bodleian Library and the Bodleian Library. The former was founded by John Radcliffe, who died in 1714, and by a bequest of £1500 a year, the income of which was used to purchase books. The library was opened in 1749. Mr. Bodley resolved to combine their purchases of books and minor literature. When the university books were built in 1860, the trustees of the Bodleian Library were transferred to the museum. The complete arrangement made the Radcliffe the new library. The Taylor Institution is one of the most valuable libraries in the city. It was founded by Robert Taylor, an architect, who died in 1798, and was established in 1801. The library was established in 1801, and contains a large collection of books, and is one of the most valuable libraries in the city.

many volumes of pamphlets) and 250 MSS. It has scientific and topographical collections. The library of Merton College has of late devoted itself to foreign modern history. New College Library has about 17,000 printed volumes and about 350 MSS., several of which were presented by its founder, William of Wykeham. Oncl College Library, besides its other possessions, has a special collection of books on comparative philology and mythology, with a printed atlas. The library of Queen's College is strong in the study of English and modern European history, and in English county histories. St John's College Library is largely composed of the literature of theology and jurisprudence before 1750, and possesses a collection of medical books of the 16th and 17th centuries. The newer half of the library building was erected by Mr. J. N. at the expense of £100,000, which gave many printed and manuscript books. The library of Trinity College formed part of Durham College, the library of which was established by Richard Bury. William Collins, Trinity College, has a collection of botanical books purchased by Richard Womer in 1775 and a collection of books relating chiefly to the Spanish Reconquest presented by the executor of Benjamin Wallin. Worcester College Library has of late specially devoted itself to classical archaeology. It is also rich in plays.

It must be admitted that the libraries as a rule have not been used to any great extent. Of late, however, there have been signs of awakening in it. At 1871 there was a meeting of college librarians, and it was agreed that the colleges must do something more to make the public use of the whole field of literature, and rather than limit their limited resources and restrict themselves to a few special departments, they must try to do something more to make the libraries available to the public and to the student.

Cambridge.

The history of the University Library at Cambridge dates from the earlier part of the 15th century. Two early lists of its contents are preserved, the first embracing 22 volumes dating from about 1420, the second a shelf list, apparently of 330 volumes, drawn up by the outgoing proctors in 1473. Its first great benefactor was Thomas Scott of Rotherham, archbishop of York, who erected in 1475 the building in which the library continued until 1755. He also gave more than 200 books and manuscripts to the library, some of which still remain. The library received other benefactions, but nevertheless appeared 'but mean' to John Evelyn when he visited Cambridge in 1654. In 1666 Robert Rustic presented a sum of money to be invested to buy the choicest and most useful books. In 1715 George I. presented the library of Bishop Moore, which was very rich in early English printed books, forming over 30,000 volumes of printed books and manuscripts. The funds bequeathed by William Worts and John Minstie, together with that of Juat, produce at present about £1500 a year. The share of university dues appropriated to library purposes amounts to £3000 a year. In addition the library is entitled to new books under the Copyright Acts. The number of printed volumes in the library cannot be exactly stated, as no recent calculation on the subject exists. It has been variously estimated at a quarter or half a million. The *Cambridge University Library Catalogue* states it is 200,000. It includes a fine series of *editio princeps* of the classics and of the early productions of the English press. The MSS. number 5723, in which are included a considerable number of advertisements or printed books with MS. notes, which form a leading feature in the collection. The most famous of the MSS. is the celebrated copy of the four gospels and the Acts of the Apostles, which is known as *Codex Bezae*, and which was presented to the university by that Reformer. A catalogue of the MSS. has been published in 4 vols., 1856-61. There is no printed catalogue of the books, although the catalogue is in print, the accessions being printed and cut up and arranged in volumes. The regulations of the library with regard to the lending of books are very liberal, as many as ten volumes being allowed out to one borrower at the same time.

There is a library attached to the Fitzwilliam Museum bequeathed to the university in 1816. It consists of the entire library of Lord Fitzwilliam, with the addition of an archaeological library bought

from the executors of Colonel Leake and a small library of works chiefly on the history of art, since acquired by purchase or bequest. It contains a collection of engravings of old masters, a collection of music, printed and MS., and a collection of illuminated MSS., chiefly French and Flemish, of the 15th to 16th centuries. The books are not allowed to be taken out.

The library of Trinity College, which is contained in a magnificent hall built by Sir Christopher Wren, has about 90,000 printed and 1918 MS. volumes, and is especially strong in theology, classics, and bibliography. It owes to numerous gifts and bequests the possession of a great number of rare books and manuscripts. Amongst these special collections are the Capell collection of early dramatic and especially Shakespearean literature, the collection of German theology and philosophy bequeathed by Aichdason Hue and the Gylls bequest in 1863 of 9000 volumes, including many early printed books. There are printed catalogues of the Sanskrit and other Oriental MSS. by Dr. Aufrecht and Professor Palmer and of the manuscripts by the present librarian, Mr. Sinker. The library is open to all members of the college, and the privilege of using it is liberally extended to properly accredited students.

None of the other college libraries rivals Trinity in the number of books. The library of Christ's College received its first books from the French. Christ's College Library includes a number of Italian and Spanish plays of the end of the 16th century left by George Lull. The library of Corpus Christi College first became notable through the gift of books and MSS. made by Archbishop Laud in 1633. The printed books are less than 5000 in number, and the additions now made are chiefly in such branches as the history of the extremely valuable collection of ancient MSS., which it possesses from all parts of Europe. There is a printed catalogue of this MSS. G. W. and Cam's College Library is of early foundation. A catalogue of the MSS. was printed in 1849, with printed illustrations, and a list of the incunabula in 1850. The printed books of King's College includes the fine collection of the library of the late King in 1804. The MSS. are almost wholly Oriental, chiefly Persian and Arabic, and a catalogue of them has been printed. Magdalen College possesses the curious library of the late King, which he bequeathed by him to the college, together with his collections of prints and drawings and of rare British prints. It is remarkable for its treasures of popular literature and English ballad, as well as for the Scottish manuscript poetry collected by Sir Robert Montagu. The books are kept in Pepys's own arrangement, as he arranged them himself. The library of Lettice is the oldest library in Cambridge, and possesses a catalogue of some 600 or 700 books dating from 1418 in which year it was completed. It is chiefly theological, though it possesses a valuable collection of modern works on theology and natural science and a unique collection of MS. music. Queen's College Library contains about 30,000 volumes, mainly in theology, classics, and Semitic literature, and has a printed catalogue. The library of St John's College is rich in early printed books, and possesses a large collection of English historical materials. Of the MSS. and rare books there is a printed catalogue. For the other college libraries see the tables.

*Free Public Libraries*.—In the year 1850 Mr. Ewart introduced the first Public Libraries Act into the House of Commons, and it has since been supplemented and amended by the Acts of 1855, 1866, 1871, and 1877. Mr. Ewart had previously carried through parliament the Museums Act of 1845, and small libraries had been established in connexion with museums, under that Act at Salford and Warrington. The number of towns which have established rate supported libraries, or in which the Acts have been adopted, now amounts to at least ninety-six, ten of these towns being in Scotland, and one only in Ireland. It is noticeable that the Acts have not been adopted in any of the great capital towns of the three kingdoms, except in one single parish of Westminster. Many of our largest towns are also in default. Glasgow may be considered to be sufficiently provided for by the munificent Mitchell bequest. Of the libraries which have actually been opened sixteen are in towns of over 100,000 inhabitants, twenty in towns between 50,000 and 100,000 inhabitants, sixteen in towns between 30,000 and 50,000, eleven in towns between 20,000 and 30,000 inhabitants, seventeen in towns between 10,000 and 20,000 inhabitants, and finally five in towns of less than 10,000 inhabitants.

Taking the latest

which are with a few exceptions those of the year 1880-81, the number of volumes in stock and of the total issues is as follows. In eighty-one libraries returning their number of volumes, there is a total of 1,448,192 volumes in stock; while the total issues for the year in seventy-six libraries amounted to the enormous number of 9,023,742 volumes. Even these figures afford a very inadequate idea of the service rendered by these institutions in supplying popular reading. They take no account of the visits made to the newsrooms which are almost invariably connected with the libraries, or of the use made of the magazines and periodicals which lie upon the tables. The free public libraries generally consist of a lending department, with a reference library wherever the institution can provide one. A very large proportion of the issues from the lending departments consists of fiction, the percentage varying in different libraries from about 50 to as much as 75 per cent. of the whole. It is only in the case of the wealthier institutions, such as those in the great towns of Liverpool, Manchester, and Birmingham, that the reference departments are so important as to claim consideration here in respect of the intrinsic character of their collections. Even some of the smaller libraries, however, present features of interest in their collection of local books, or of books illustrating the trade or industry of the district, or the life and writings of some great man connected with or born in the locality.

The Salford Free Public Library was one of the libraries which were established under the Museums Act of 1845, and was opened in connexion with the museum and picture gallery at Peel Park. The buildings are pleasantly situated on grounds of 46 acres in extent. The reference library now contains 33,500 volumes, and besides the central lending departments there are three branches in different parts of the borough. The income from the penny rate is about £3300; but this is found to be inadequate.

The Manchester Free Library was the first to be established under the Act of 1850. A public subscription of nearly £13,000 was raised to defray the expenses of its establishment, and the library was opened in September 1852. The working of this library was a success from the outset. The issues in the first year were in the reference departments 61,080 volumes, and in the lending departments 77,332. The progress made since then may be measured by the number of volumes issued last year (1881), which amounted to 966,468, and by the fact that six branch libraries have been established. The rate produces an income of £11,600. The reference library now possesses a valuable collection of 65,000 volumes, chiefly of standard works. It contains several special collections, chiefly connected with the industries and history of the district. The library of the English Dialect Society, of which a catalogue has been printed, is deposited here. In addition, the library possesses a very extensive series of periodicals, and a larger collection of political and commercial tracts than can be found anywhere in the country except at the British Museum. A good catalogue was printed in 1864, and a new and extensive index has just appeared.

The library at Liverpool, which was established under a special Act passed in 1852, is the most successful of all the free public libraries, and is connected with a splendid museum and art gallery, the former formed around the nucleus of the ornithological specimens bequeathed to the town by the thirteenth earl of Derby. The rapid extension of museum and library soon rendered larger premises a necessity. The late Sir William Brown took upon himself the entire cost of the present extensive buildings, which were opened in 1860. In 1880 was opened the Picton Reading-Room. It is a circular room 100 feet in diameter, surmounted by a dome, the entire height being 56 feet. It contains 50,000 volumes, and will accommodate over 300 readers. Since April 1881 the electric light has been employed. Under the reading-room is a large circular lecture-room accommodating 1500 persons, in which lectures are regularly delivered. There is a numerous collection of local books and pamphlets. The Binns collection, consisting of maps, plans, drawings, portraits, &c., all having reference to the county of Lancaster, is very interesting and valuable. The issues from the reference library in 1880 were 870,716, and with the issues from the two lending departments make the enormous aggregate of 1,307,131. The rate produces an income of £13,000 per annum, of which more than £5000 is expended upon the libraries. An elaborate catalogue of the reference library was published in 1872, and a supplement is now being printed. In 1853 Bolton established a library which now has a circulation

of over 240,000 volumes. In 1855 libraries were established at Birkenhead and Sheffield. At Birkenhead the rate produces £1500, and 130,000 volumes were lent out last year. At Sheffield, where the rate produces £4750, there are three branches, and the total issues last year were 384,266. The reference library has only 9000 volumes.

The Acts, after having been rejected at Birmingham in 1852, were adopted in 1860. By 1868 four branches had been opened in addition to the central reference and lending libraries. The issues from the lending departments last year were 400,060 volumes. The reference library consisted of over 50,000 volumes. The Shakespeare Memorial Library consisted of about 7000 volumes. There were also the Staunton Warwickshire collections of books and MSS., and the Cervantes book. All these collections were unfortunately destroyed by a fire on January 11, 1879. The inhabitants of Birmingham have shown much public spirit in repairing the losses then sustained so far as is possible, and the new central reference and lending libraries are expected to be open early in 1882, when it is anticipated that there will be as many volumes ready to be placed in the reference library as there were when the former library was destroyed. No town in England is so surrounded with free libraries as Birmingham. The rate at Birmingham produces over £6000.

The free library at Nottingham (1867) has recently had new quarters found for it in the new university buildings. It has two branches, and its issues are about 100,000. The rate produces £2200. The local collections include a Byron library. The library at Leeds (1868) has no less than twenty-one branches, and together they count over 100,000 volumes. The issues last year, in addition to the use made of the central reference library, were 639,613. The rate produces nearly £5000. At Leicester there is only a halfpenny rate, which produces about £400. The issues last year were 192,317. At Bradford (Acts adopted 1871) the rate produces £3200, and there are five branches with a circulation of 291,276 volumes. Besides the use made of the reference library. At Plymouth (Acts adopted 1871) library opened 1876, the circulation was 171,851 last year; at Rochdale (Acts adopted 1872) 168,514. At each place there is a good collection of local literature, and at Rochdale a collection of works on the woollen manufacture. The library at Newcastle, opened in 1880, has issued from its lending departments, in its first year, no less than 301,325 volumes to about 14,000 readers. A splendid building is in course of erection to accommodate the reference library. This department is intended to contain a complete collection of all standard works, and also a collection of books and manuscripts relating to Newcastle and the northern counties generally. The rate produces £2800. At Bristol a town library had been established in 1814 by Robert Redwood and A. H. Ship Matthew, and this has formed the nucleus of the collection. Under the Acts when they were adopted in 1855, the total reference volumes is about 46,000. The issues were 432,646 at the first library and its three branches. At Southampton (1855) Mr. Henson gave the building called after him for a library and art gallery. The issues last year were 110,778. The rate produced £775, and an additional voluntary rate produced a little over £400 last year.

It will be seen from this summary statement that the libraries established under the Acts have in the cases mentioned been abundantly used. The merit of these results is very largely due to the enlightened energy of those who have aided the administration.

Amongst the English libraries that have not yet been described there are few that call for special mention. Some of these have been founded by individuals, and still bear their names. The most notable of these is the fine old library established by Humphrey Chetham at Manchester in 1653, which is still housed in the old collegiate buildings where Chetham was once entertained by Dr. Dee. The collection consists largely of classical literature, and numbers 40,000 volumes, with 100 MSS. It is freely open to the public, and may be said to have been the first free library in England. Dr. Shepherd's library at Preston was bequeathed by the founder, a physician of the town, to the corporation of Preston in trust for the inhabitants in the year 1759. It is a library of reference, accessible on a recommendation from an alderman. The William Salt Library, a special Staffordshire library with numerous MSS., and other collections formed by bringing together materials for a history of Staffordshire, was opened to the public in 1874.

Some mention should be made also of the more important subscription or proprietary libraries, which were founded for the most part in the latter half of the 18th century. It is difficult for us to realize how few collections of books were accessible to the public of the last century. The earliest circulating library in the metropolis was founded about the middle of the century. The first subscription library was opened by Hutton in 1757. The idea of a proprietary library appears to have been first carried out at Liverpool in 1758. The library then formed still flourishes at the Liverpool, and possesses a collection of 72,000 volumes and an income of £1000 a year. In 1760 a library was formed at Warrington which has been merged

in the Warrington Museum. The Leeds library was established in 1768, and now has 85,000 volumes, and an income of £1430. In 1772 the Bristol museum and library was formed, and numbered Coleridge, Southey, and Landor among its earlier members. It now reckons 50,000 volumes, and an income of £1400 a year. The Birmingham (old) library was formed in 1779, and its rules were drawn up by Dr Priestley, who had already taken an active share in the management of the libraries at Warrington and Leeds. The library has now 40,000 to 50,000 volumes, and an income of £1600. Many similar institutions are noticed in the tables, while others have given place to the trade circulating libraries and to the libraries established under the Free Libraries Acts.

A few modern collegiate libraries, finally, claim a summary notice. The library of the university of Durham dates only from 1833, and was begun by a gift of books from Bishop Van Mildert, to which many other donations have since succeeded. The Routh collection includes a large collection of early tracts. The Winterbottom collection is chiefly classical, and the Maltby collection classical and theological. The library of the Owens College, Manchester, was formed on the establishment of the college in 1851 by a gift of books from Mr James Heywood, F.R.S. It has since been largely increased by donations and bequests, including the libraries of Bishop Lee, Mr Crace Calvert, and others. It has an endowment fund of £2500. The library at Stonyhurst College has gradually grown since the establishment of the college in 1794. There is a printed catalogue of books printed before 1551. The Walshian Library at St Mary's College, Oscott, was established by Bishop Walsh in 1839, having been purchased by him from the Marchese Marina. It has 70 MSS. and many early printed books.

Scotland. The principal library in Scotland is that of the Faculty of Advocates, who in 1680 appointed a committee of their number, which reported that "it was fit that, seeing if the recusants could be made pay their entire money, there wold be betwixt three thousand and four thousand pounds in cash; that the same be employed on the best and fynest lawers and other law bookes, conforme to a catalogue to be condescended upon by the Facultie, that the samen may be a fonde for ane Bibliothecque whereto many lawers and others may leave their books." In 1682 the active carrying out of the scheme was committed to the Dean of Faculty, Sir George Mackenzie of Rosehaugh, who may be regarded as the founder of the library. In 1684 the first librarian was appointed, and the library appears to have made rapid progress, since it appears from the treasurer's accounts that in 1686 the books and furniture were valued at upwards of £11,000 Scots, exclusive of donations. In the year 1700, the rooms in the Exchange Stairs, Parliament Close, in which the library was kept, being nearly destroyed by fire, the collection was removed to the ground floor of the Parliament House, where it has ever since remained. The library retains the copyright privilege conferred upon it in 1709. The number of volumes in the library is computed to amount to 265,000; of the special collections the most important are the Astorga collection of old Spanish books, purchased by the faculty in 1824 for £1000; the Thorkelin collection, consisting of about 1200 volumes relating chiefly to the history and antiquities of the northern nations, and including some rare books on old Scottish poetry; the Dietrich collection of over 100,000 German pamphlets and dissertations, including many of the writings of Luther and Melancthon, purchased for the small sum of £80; and the Combe collection.

The faculty appear early to have turned their attention to the collection of MSS., and this department of the library now numbers about 3000 volumes. Many of them are of great interest and value, especially for the civil and ecclesiastical history of Scotland before and after the Reformation. There are thirteen monastic chartularies which escaped the destruction of the religious houses to which they belonged. The MSS. relating to Scottish church history include the collections of Spottiswoode, Woodrow, and Calderwood. The Woodrow collection consists of 154 volumes, and includes his correspondence, extending from

1694 to 1726. Sir James Balfour's collection and the Balcarras papers consist largely of original state papers, and include many interesting royal letters of the times of James V., Queen Mary, and James VI. The Sibbald papers, numbering over 30 volumes, are largely topographical. The Riddel notebooks, numbering 156 volumes, contain collections to illustrate the genealogy of Scottish families. There are about one hundred volumes of Icelandic MSS., purchased in 1825 from Professor Finn Magnusson, and some Persian and Sanskrit, with a few classical manuscripts. The department has some interesting treasures of old poetry, extending to 73 volumes. The most important are the Bannatyne MS., in 2 vols. folio, written by George Bannatyne in 1568, and the Auchinleck MS., a collection of ancient English poetry, named after Alexander Boswell of Auchinleck, who presented it in 1774.

The first catalogue of the printed books was compiled in 1692, and contains a preface by Sir George Mackenzie. Another was prepared under the care of Ruddiman in 1712. In 1853 the late Mr Halkett commenced a catalogue, which has been printed in 6 vols. 4to, with a supplement, and includes all the printed books in the library at the end of 1871, containing about 260,000 entries. It is an illustration of the public spirit with which they conduct their library, that the whole cost of printing this extensive catalogue, over £5000, has been borne by the members of the faculty. The library, managed by a keeper and staff, under a board of six curators, is easily accessible to all persons engaged in literary work, and is for all practical purposes the public consulting library of Scotland.

The origin of the University Library of Edinburgh is to be found in a bequest of his books of theology and law made to the town in 1580 by Clement Little, advocate. This was two years before the foundation of the university, and in 1584 the town council caused the collection to be removed to the college, of which they were the patrons. As it was the only library in the town, it continued to grow and received many benefactions, so that in 1615 it became necessary to erect a library building. Stimulated perhaps by the example of Bodley at Oxford, Drummond of Hawthornden made a large donation of books, of which he printed a catalogue in 1627, and circulated an appeal for assistance from others. In 1678 the library received a bequest of 2000 volumes from the Rev. James Nairne. In 1709 the library became entitled to the copy privilege, which has since been commuted for a payment of £575 per annum. In 1831 the books were removed to the present library buildings, for which a parliamentary grant had been obtained. The main library hall (190 feet in length) is one of the most splendid apartments in Scotland. One of the rooms is set apart as a memorial to General Reid, by whose benefaction the library has greatly benefited. Amongst the more recent accessions have been the Halliwell-Phillips Shakespeare collection, the Laing collection of Scottish MSS., the Baillie collection of Oriental MSS. (some of which are of great value), and the Hodgson collection of works on political economy. The library now consists of about 140,000 volumes of printed books with 2000 MSS.

The library of the Writers to Her Majesty's Signet was established by the society in 1755. At first it consisted of law books exclusively, but in 1788 they began to collect the best editions of works in other departments of literature. During the librarianship of Macvey Napier (1805-37) the number of volumes was more than sextupled, and in 1812 the library was removed to the new hall adjoining the Parliament House. In 1834 the upper hall was devoted to the collection. This is a magnificent apartment

142 feet long, with a beautiful cupola painted by Stothard. The library now contains nearly 70,000 volumes, exclusive of pamphlets, and includes some fine specimens of early printing, as well as many other rare and costly works. It is especially rich in county histories and British topography and antiquities. A catalogue of the law books was printed in 1856. The late David Laing, who became librarian in 1837, published the first volume of a new catalogue in 1871. The second volume is nearly completed. The books are lent out to the Writers and even to strangers recommended by them. This library, like that of the Advocates, is most liberally opened to literary inquirers, and has thus acquired a quasi public or national character.

There are various other important libraries in Edinburgh, but no considerable lending library open freely to the poorest of the people, and two attempts which have been made to introduce the Libraries' Acts have been unsuccessful.

The first mention of a library at St. Andrews is as early as 1456. The three colleges were provided with libraries of their own about the time of their foundation: St. Salvador's 1455, St. Leonard's 1512, St. Mary's 1537. The University Library was established about 1612 by King James VI., and in the course of the 18th century the college libraries were merged in it. The copyright privilege was commuted in 1837. The collection numbers 90,000 volumes exclusive of pamphlets, with about 200 MSS., chiefly of local interest. About 1200 volumes are added yearly. A library is supposed to have existed at Aberdeen since the foundation of King's College by Bishop Elphinstone in 1494. The present collection combines the libraries of King's College and Marischal College, now incorporated in the university. The latter had its origin in a collection of books formed by the town authorities at the time of the Reformation, and for some time kept in one of the churches. The library has enriched by the Melvin bequest, chiefly of classical books, and those of Henderson and Wilson, and contains some very valuable books. The general library is located in Old Aberdeen, while the medical and law books are in the New Town. The library has a grant, in lieu of the copy privilege, of £320. The library of the university of Glasgow dates from the 15th century, and numbers George Buchanan and many other distinguished men amongst its early benefactors. A classified subject-catalogue is in progress. The annual accessions are about 1500, and the commutation-grant £707. Connected with the university, which is trustee for the public, is the library of the Hunterian Museum, formed by the eminent anatomist Dr. William Hunter. It is a collection of great bibliographical interest, as it is rich in MSS. and in fine specimens of the early printing, especially in Greek and Latin classics. The printed books number about 13,000 volumes, and the MSS. some 600 volumes. All the Scottish university libraries lend books to students, on deposit of £1, to graduates, for an annual subscription of half a guinea, and to persons engaged in literary research, by permission of the senatus.

The Mitchell Library at Glasgow holds for to be the most important public library outside Edinburgh. It was founded by a magnificent bequest of £70,000 from the late Mr. Stephen Mitchell. The library was opened in 1877, in temporary premises, and already contains over 36,000 volumes. It includes a special collection of Scottish poetry called "The Poet's Corner," and a collection of Glasgow literature, including early specimens of Glasgow printing. The library is open to all persons over fourteen years of age, and the number of readers during the first three years in which the library has been opened is believed to be without precedent. The number of volumes issued in 1880 was 390,732.

The English Libraries Act of 1850 was extended to Scotland in 1854, and the first town to put it into operation was Airdrie, in 1856. The largest of the libraries which have been opened under the Acts is at Dundee, which possesses 35,500 volumes, with a circulation of 252,314. The rate produces £2300. Although the resources of the other towns in which the Acts have so far been adopted do not enable them to rival the larger English towns, the results are proportionately quite as satisfactory. The turnover of their stock of books is generally large, and the reading done appears to be more solid and serious than in England. The percentage of fiction issued is at least 10 or 15 per cent. below the average rate in the English free libraries.

**Ireland.** The establishment of the library of Trinity College, Dublin, is contemporaneous with that of the Bodleian at Oxford, and it is an interesting circumstance that, when Challoner and Ussher (afterwards the archbishop) were in London purchasing books to form the library, they met Bodley there, and entered into friendly intercourse and co-operation with him to procure the choicest and best

books. The commission was given to Ussher and Challoner as trustees of the singular donation which laid the foundation of the library. In the year 1601 the English army determined to commemorate their victory over the Spanish troops at Kinsale by some permanent monument. Accordingly they subscribed the sum of £1800 to establish a library in the university of Dublin. For Ussher's own collection, consisting of 10,000 volumes and many valuable MSS., the college was also indebted to military generosity. On his death in 1655 the officers and soldiers of the English army then in Ireland purchased the whole collection for £22,000 with the design of presenting it to the college. Cromwell, however, interfered, alleging that he proposed to found a new college, where the books might more conveniently be preserved. They were deposited therefore in Dublin Castle, and the college only obtained them after the Restoration. In 1674 Sir Jerome Alexander left his law books and valuable MSS. to the college. In 1726 Dr. Halpern, archbishop of Cashel, bequeathed over 1000 volumes to the library, and ten years later Dr. Gillert gave the library nearly 13,000 volumes which he had himself collected and arranged. In 1741 the library received a valuable collection of MSS. as a bequest from Dr. Stanihurst. In 1802 the collection formed by the pensionary Engel, which had been removed to England on the French invasion of Holland, was acquired for £10,000. It consisted of over 20,000 volumes. In 1805 Mr. Quin bequeathed a choice collection of classical and Italian books. There have been many other smaller donations, in addition to which the library is continually increased by the books received under the Copyright Act. The library now contains 192,000 volumes and 1880 MSS., and about 3000 volumes are added every year. There is no permanent endowment, and purchases are made by grants from the board. The whole collections are contained in one building, erected in 1732, consisting of eight rooms. The great library hall is a magnificent apartment over 200 feet long. A new reading room was opened in 1848. A catalogue of the books acquired before 1872 is now in course of printing. There is no printed catalogue of the MSS. Graduates of Dublin, Oxford, and Cambridge are admitted to read permanently, and temporary admission is granted by the board to any fit person on application. Books and MSS. are lent under special regulations. A lending library is established to make provision for the needs of the

public. The public library at Dublin was established by the will of the late Archbishop Marsh, who died in 1797, and endowed with £10,000. The library was erected in 1801, and the original collection consisted of 10,000 volumes, and 100 MSS. There is no modern books. The endowment is too small to allow of the library, so that it still retains the books of the original library. The books are chiefly in Latin and French, and they include the library of the late Archbishop Marsh, a French collection of 10,000 volumes, and a collection of 10,000 volumes. The library of the late Archbishop Marsh was continued shortly after the formation of the library. With a collection of about 10,000 volumes, and a few early editions, its books were transferred to the library in 1872, to assist in forming the national library of Ireland. The manuscript collections of Walter Harris, a Irish history were purchased and placed in the library for public use by the Irish people. The library of the Royal Irish Academy was established on the formation of the Academy, and the purpose of the library was to collect the books of the Academy in Ireland. The library possesses about 10,000 MSS. and about 11,000 printed books. There is a large collection of MSS. and printed books relating to the history, ancient language, and antiquities of Ireland. They include the Bodleian collection, and are supported by public subscription in 1851. The library is supported by a Government grant of £200 per annum, and is open on a proper introduction. Under the direction of the present honorary

librarian, the publication of Irish MSS. in the library was begun in 1870, and has since continued. The library of King's Inns was founded, pursuant to a bequest of books and legal MSS. under the will of Mr Justice Robinson in 1787, to form the nucleus of a library for law students. It is partly supported from the funds of the benchers, but partly also by a treasury grant of £433, 6s. 8d. in lieu of the copy privilege. No books are lent out, and the use of the library is confined to students and barristers; so that the public has no advantage in return for the annual contribution of public money.

There is no library in Dublin corresponding in extent and public accessibility to the British Museum in London, or the Advocates' Library in Edinburgh. About 1850 it was proposed to supply the deficiency by combining the libraries of the Dublin Society and the Irish Academy, both of which had long received grants of public money, together with the collection of Archbishop Marsh. Accordingly in 1854 an Act of Parliament was passed "for the establishment of a national gallery and for the care of a public library in Dublin." The scheme thus authorized has never been carried out. In 1877, however, the National Library of Ireland was established in the apartments of Leinster House. The library is under the Science and Art Department of South Kensington, and is superintended by a body of twelve trustees in Dublin. For the last two years it has received an annual vote of £1000 from parliament for the purchase of books. As already mentioned, the books of the Royal Dublin Society have been transferred to it. It is freely open to the public on a respectable introduction, and is much used.

The public library of Armagh was founded by Lord Primate Robinson in 1770, who gave a considerable number of books and an endowment. The books are freely available, either on the spot, or by loan on deposit of double the value of the work applied for. At Belfast the Queen's College Library has about 36,000 volumes, with a special collection of books on the languages and literatures of the East. The library of the Queen's College, Cork, contains about 25,000 volumes, 1600 of the most valuable of which have been presented by Mr Crawford. The library is easily accessible to literary inquirers, and is much used by strangers. The library of Maynooth College is chiefly theological, and contains the collections bequeathed by the late "resident," Monsignor Russell. There are about 40,000 volumes and a few MSS.

Dundalk is at present the only town that has a library under the Public Libraries Acts, which were adopted there in 1856. The rate produces only about £50.

#### France.

**France.** French libraries (other than those in private hands) belong either to the state, to the departments, to the communes, or to learned societies, educational establishments, and other public institutions; the libraries of judicial or administrative bodies are not considered to be owned by them, but to be state property. Besides the unrivalled library accommodation of the capital, France possesses a remarkable assemblage of provincial libraries. The communal and school libraries also form striking features of the French free library system.

Five and twenty years ago (see *Tableau statistique des bibliothèques publiques*, 1857) there were in the departments,—exclusive of those not literally free, and of all Parisian libraries,—340 public libraries containing 3,734,260 volumes and 44,436 MSS. In 1857 there were only 32 provincial libraries which owned more than 30,000 volumes each; there are now 54 which are of that extent and upwards.<sup>1</sup> In Paris there are now 16 containing over 30,000 volumes each.

**Paris.** *Libraries of Paris.*—The Bibliothèque Nationale (still the most extensive library in the world) has had an advantage over all others in the length of time during which its contents have been accumulating, and in the great zeal shown for it by several kings and other eminent men. Enthusiastic writers find the original of this library in the MS. collections of Charlemagne and Charles the Bald, but these were dispersed in course of time, and the few precious relics of them which the national library now possesses have been acquired at a much later date. Of the library which St Louis formed in the 13th century

(in imitation of what he had seen in the East) nothing has fallen into the possession of the Bibliothèque Nationale, but much has remained of the royal collections made by kings of the later dynasties. The real foundation of the institution (formerly known as the Bibliothèque du Roi) may be said to date from the reign of King John, the Black Prince's captive, who had a considerable taste for books, and bequeathed his "royal library" of MSS. to his successor Charles V. Charles V. organized his library in a very effective manner, removing it from the Palais de la Cité to the Louvre, where it was arranged on desks in a large hall of three stories, and placed under the management of the first librarian and cataloguer, Claude Mallet, the king's valet-de-chambre. His catalogue was a mere shelf-list, entitled *Inventaire des Livres du Roy nostre Seigneur exans au chasteau du Louvre*; it is still extant, as well as the further inventories made by Jean Blanchet in 1380, and by Jean le Bègue in 1411 and 1424. Charles V. was very liberal in his patronage of literature, and many of the early monuments of the French language are due to his having employed Nicholas Oresme, Raoul de Presle, and other scholars to make translations from ancient texts. Charles VI. added some hundreds of MSS. to the royal library, which, however, was sold to the regent, duke of Bedford, after a valuation had been established by the inventory of 1424. The regent transferred it to England, and it was finally dispersed at his death in 1435. Charles VII. and Louis XI. did little to repair the loss of the precious Louvre library, but the news of the invention of printing served as a stimulus to the creation of another one, of which the first librarian was Laurent Paulmier. The famous miniaturist Jean Fouquet of Tours was named the king's *enlumineur*, and although Louis XI. neglected to avail himself of many precious opportunities that occurred in his reign, still the new library developed gradually with the help of confiscation. Charles VIII. enriched it with many fine MSS. executed by his order, and also with most of the books that had formed the library of the kings of Aragon, seized by him at Naples. Louis XII., on coming to the throne, incorporated the Bibliothèque du Roi with the fine Orleans library at Blois, which he had inherited. The Blois library, thus augmented, and further enriched by plunder from the palaces of Pavia, and by the purchase of the famous Gruthuyse collection, was described at the time as one of the four marvels of France. Francis I. removed it to Fontainebleau in 1534, enlarged by the addition of his private library. He was the first to set the fashion of fine artistic bindings, which was still more cultivated by Henry II., and which has never died out in France. During the librarianship of Amyot (the translator of Plutarch) the library was transferred from Fontainebleau to Paris, not without the loss of several books coveted by powerful thieves. Henry IV. removed it to the Collège de Clermont, but in 1604 another change was made, and in 1622 it was installed in the Rue de la Harpe. Under the librarianship of J. A. de Thou it acquired the library of Catherine de' Medici, and the glorious Bible of Charles the Bald. In 1617 a decree was passed that two copies of every new publication should be deposited in the library, but this was not rigidly enforced till Louis XIV.'s time. The first catalogue worthy of the name was finished in 1622, and contains a description of some 6000 volumes, chiefly MSS. Many additions were made during Louis XIII.'s reign, notably that of the Dupuy collection, but a new era dawned for the Bibliothèque du Roi under the patronage of Louis XIV. The enlightened activity of Colbert, one of the greatest of collectors, so enriched the library that it became necessary for want of space to make another removal. It was therefore in 1666 installed in the Rue Vivien (now Vivienne) not far from its present habitat.

<sup>1</sup> In 18— a questionnaire was issued in order to obtain materials for a more complete report, but the results have not yet been made public.

The departments of engravings and medals were now created, and before long rose to nearly equal importance with that of books. Marolles's prints, Fouquet's books, and many from the Mazarin library were added to the collection, and, in short, the Bibliothèque du Roi had its future pre-eminence undoubtedly secured. Nic. Clément made a catalogue in 1684 according to an arrangement which has been followed ever since (that is, in twenty-three classes, each one designated by a letter of the alphabet), with an alphabetical index to it. After Colbert's death Louvois emulated his predecessor's labours, and employed Mabillon, Thevenot, and others to procure fresh accessions from all parts of the world. A new catalogue was compiled in 1688 in eight volumes by several distinguished scholars. The Abbé Louvois, the minister's son, became head of the library in 1691, and opened it to all students—a privilege which although soon withdrawn was afterwards restored. Towards the end of Louis XIV.'s reign it contained over 70,000 volumes. Under the management of the Abbé Bignon numerous additions were made in all departments, and the library was removed to its present home in the Rue Richelieu. Among the more important acquisitions were 6000 MSS. from the private library of the Colbert family, Bishop Huet's forfeited collection, and a large number of Oriental books imported by missionaries from the further East, and by special agents from the Levant. Between 1739 and 1753 a catalogue in eleven volumes was printed, which enabled the administration to discover and to sell its duplicates. In Louis XVI.'s reign the sale of the La Vallière library furnished a valuable increase both in MSS. and printed books. A few years before the Revolution broke out the latter department contained over 300,000 volumes and opuscles. The Revolution was serviceable to the library, now called the Bibliothèque Nationale, by increasing it with the forfeited collections of the *émigrés*, as well as of the suppressed religious communities. In the midst of the difficulties of placing, and cataloguing these numerous acquisitions, the name of Van Praet appears as an administrator of the first order. Napoleon increased the amount of the Government grant; and by the strict enforcement of the law concerning new publications, as well as by the acquisition of several special collections, the Bibliothèque made considerable progress during his reign towards realizing his idea that it should be universal in character. At the beginning of this century the recorded numbers were 250,000 printed volumes, 83,000 MSS., and 1,500,000 engravings. After Napoleon's downfall the MSS. which he had transferred from Berlin, Hanover, Florence, Venice, Rome, the Hague, and other places had to be returned to their proper owners. The MacCarthy sale in 1817 brought a rich store of MSS. and incunabula. From that time onwards to the present, under the enlightened administration of MM. Taschereau and Delisle, the accessions have been very extensive.

The official estimate of the number of volumes in the *Département des Imprimés* now reaches the extraordinary total of about 2,290,000, but the contents have not been actually counted since 1791, and as the above enumerates pieces of which many are included in one volume, perhaps something like 1,827,000 is nearer the proper number. The annual additions are about 15,000. The *réserve* (consisting of articles of the highest importance) extends to more than 50,000 volumes. The collection of books on French history is in itself an enormous library, amounting to 440,000 volumes. The maps and charts, said to number 300,000, are included in this department. The *Département des MSS.* comprehended, in 1876, 91,700 volumes. The *Département des Médailles* possessed, in 1873, 143,030 coins, medals, engraved stones, &c., and since that date has acquired many important accessions. More than 2,200,000 engravings are in the *Département des Estampes*, where 20,000 pieces are annually received under the copyright law. The annual vote for purchases and binding is 200,000 francs.

Admittance to the *Salle de Travail* is obtained by a *bulletin*

*personnel*, which is procurable without difficulty. This, reading-room for students, was built in 1868, and affords accommodation for 344 readers. There are but few books of reference, and readers are only allowed five books a day. The *Salle publique* contains 40,000 books, which are freely available to the public. Plans are now under consideration for an enlargement of the Bibliothèque, and a sum of 3,700,000 francs is to be devoted to that purpose.

The Bibliothèque Nationale does not possess a general catalogue at the disposal of readers; the MS. catalogues of the various classes of the printed books are for official use only. Besides the old catalogue of 1739-53, there is the very elaborate *Catalogue de l'Histoire de France* (1855-79, 11 vols. 4to), with a lithographed supplement; the indexes will appear shortly. The third volume of the *Catalogue des Sciences Médicales* is now in the press, and that devoted to English history is nearly finished in manuscript. The vellum books have been described by Van Praet (1822-23, 6 vols. 8vo, and supplement, 1874). The MSS. are much better provided for. The printed catalogues of the MSS. commence with that of Anicet Melot, 1739-41, 4 vols. folio, continued in a way by the *Notice et Extraits des MSS. du Publ. de la B. N.* 1757-1875. The work of M. Paulin Paris, *Les MSS. Français, leur histoire et celle des textes allemands, anglais, italiens, et espagnols* (1836-45, 7 vols. 8vo), is well known. Catalogues of the Italian, Spanish, Belgian, Pali, Sanskrit, Ethiopian, and Chinese MSS. have all appeared between 1807 and 1844. The first and second volumes of the new *Catalogue des MSS. Français* have been printed, and two volumes of the *Inventaire* of M. Delisle, besides five parts of the *Inventaire des MSS. Latins* (1863-71). The authorities have also brought out a *Catalogue des Manuscrits Hébreux et Samaritains* (1866, 4to), besides those of MSS. *Saracenes et Arabes* (1871, 4to), MSS. *Ethiopiens* (1877), and MSS. *Egypciens* (1879).

Paris is much better provided than London or any other city in the world with great public libraries. Besides the Bibliothèque Nationale there are four libraries, each over 100,000 volumes with others less extensive, to which the public have free access, the Bibliothèque de l'Arsenal being the largest of them. The collection of the Marquis de Paulmy d'Angenou was the basis of the library, which also acquired a portion of the books of the Duc de La Vallière in 1781. It is peculiarly rich in romances, the drama, and French poetry, and possesses 80,000 volumes on French history alone. It is freely open, but there are not many readers. The Bibliothèque Mazarine was founded by the great cardinal, who in 1643 placed about 12,000 volumes at the disposal of the public. The books were chiefly brought together through the exertions of Gabriel Naudé, who told us that in 1618 they amounted to 40,000 volumes. After the death of Mazarin, his great collection was bequeathed to the college bearing his name, and placed under the direction of the Sorbonne from 1688 to 1790, and while there it has been subject to the control of the state. It is rich in incunabula and theology, including the works of Protestant divines, and is annually visited by over 12,000 readers. The Bibliothèque Sainte Geneviève was founded in 1621 at the abbey of that name, by Cardinal François de La Rochefoucauld. Other persons also gave books, and in 1684 the library is reported to have contained 20,000 printed volumes and 400 MSS. In 1710 C. M. Le Tellier bequeathed his collection, and in 1713 the *Journal* of the same year an announcement appeared that the library would be open to students during certain hours. In 1720, Louis, Duc d'Orléans, the son of the Regent, took up his residence here, and in 1730 the library was considerably enlarged. It was opened to the public in 1790, and at the time of the Revolution there were 80,000 printed volumes and 2000 MSS. There are now 120,000 volumes and 2300 MSS. The reading room is open in the evening, and is much frequented, especially by students. The library contains a good collection of manuscripts, many of which have been described by Delisle, a number of the Italian and Spanish chronicles, and a very complete series of periodicals from the 17th century to the present. The Bibliothèque de l'Université (or the Sorbonne) was formerly restricted to the use of the members of the five faculties of Paris, but the public has been freely admitted during the last thirty years. The Bibliothèque de l'Institut having been plundered during the Revolution, the old town library was transferred to it. Books to the number are wanted for the accommodation (which last twelve months of my residence at the Bibliothèque de l'Université, founded in the 18th century, and destroyed at the time of the Revolution, was destroyed in 1793. It has since been entirely reconstructed in the Hotel Carnavalet, which contains the historical museum of the city, and comprehended 160,000 volumes of books and 40,000 engravings, entirely relating to the history and description of Paris. The other public libraries are under the authority of the minister of public instruction, but the Bibliothèque de la Ville is under the control of the préfet de la Seine. The municipal libraries in Paris are 20 in number, with 70,000 volumes; there are besides 440 school libraries, with 41,120 volumes.

Of other libraries in Paris, not included in the above, we may name the Bibliothèque de la Préfecture de la Seine, 100,000 volumes, with curious MSS. relating to the revolution, Bibliothèque du

Tribunal de première instance (28,000 volumes), Bibliothèque de l'École Polytechnique (30,000 volumes), Bibliothèque de l'École Normale (26,000 volumes, which acquired the library of Georges Cuvier in 1833), Bibliothèque des Invalides (28,000 volumes, a good collection on history and military affairs), Bibliothèque de l'École Nationale des Beaux Arts (15,000 volumes, 12,000 drawings, 100,000 prints and photographs), Bibliothèque du Conservatoire de Musique (30,000 volumes, one of the finest collections of musical literature in the world), Bibliothèque des Archives Nationales (founded by Danon in 1808, containing 25,000 volumes on paleography, history, and jurisprudence, as this is the record office of France, the archives are very extensive), Bibliothèque du Luxembourg (25,000 volumes), Bibliothèque du Lycée Louis le Grand (30,000 volumes), Bibliothèque du Ministère de l'Intérieur (17,000 volumes, including Parisian and provincial history and documents).

Pro-  
vinces of  
France.

Besides the various collections belonging to learned and scientific societies, educational institutions, and other bodies, outside Paris, over 215 French provincial towns possess public libraries, which range in number of volumes from 2000 or 3000 to 100,000, as at Bordeaux. Most of them were founded at the end of the last or the beginning of the present century, but some are earlier. The library at Lyons was established by Francis I. in 1530, that at Nantes date from 1588, La Rochelle from 1604, Abbeville, Besançon, and Troyes from the latter part of the same century, and Orléans from the beginning of the 17th century. The large majority were formed by confiscation at the time of the Revolution. In February 1790 the Assemblée Nationale abolished the different religious communities, and in September of the same year the provincial tribunals and parliaments met with the same fate. The books (said to number 10 or 12 millions) of these corporations were declared national property, a committee was appointed to consider what should be done with them, and a general catalogue of all the sequestered effects ordered to be drawn up. In consequence of the recommendations of the committee, the Convention Nationale (January 27, 1794) decreed the establishment and augmentation of public libraries. The orders of the Convention were not carefully executed, and pitiable stories are told of valuable works sold by the yard, as they lay upon the ground, of precious manuscripts and printed works left to rot in the open air or burnt "à fac". As the government became more settled, the libraries when not destroyed or condemned persons were restored to their representatives. As a large number of books still remained, however, and it is to them that the town libraries of France chiefly owe their riches. Theology, law, history, and the severer literature of the 17th and 18th centuries consequently predominate, although for many years more modern requirements have been mainly considered in the acquisition of books. Many collections of local and provincial literature have been formed, as at Angers, Amiens, Chémont, Grenoble, La Rochelle, Lille, Marseilles, Orléans, Toulouse, Tours, and Versailles. Some of the libraries are very extensive. Douai and Troyes have 100,000 volumes each; Lyons and Rouen over 120,000; Besançon, 140,000; Aix and Nantes, 150,000; Grenoble, 170,000; and Bordeaux, 180,000 volumes. All have catalogues, mostly alphabetical; a few of them are in print. The *Catalogue général des MSS. des bibliothèques publiques et de particuliers* is a noble undertaking on the part of the French Government. The first volume came out in 1819, and the last, the sixth, in 1879; the treasures of eighteen libraries have now been catalogued (about 9650 MSS.), and there remain over 45,000 MSS. to be described. Besides this, Angers, Amiens, Auxerre, Caen, Carpentras, Chartres, Orléans, and Tours possess separate printed catalogues of their MSS. The chambers annually vote large sums for book, which are distributed to the town libraries by the minister of public instruction. The sums granted by the different municipalities for their libraries vary in amount; for instance, Grenoble (170,000 volumes and eight persons) gives 26,314 francs, Bordeaux (170,000 volumes and eight persons) 21,500 francs, and Nantes (170,000 volumes and four persons) 15,600 francs.

Popular libraries of every description, including military and workmen's libraries, owe much to the "Société Franklin pour la propagation des bibliothèques populaires," which, founded in 1862, has since been of immense service in organizing and helping these institutions. Betsy (in 1865 and 1875 the latter had spent 5500 francs) — see p. 100. It issues a *Catalogue de la Bibliothèque* of a good selection of recommended books, and publishes a journal of its proceedings.

School libraries had an organized existence in France as far back as 1831, and by 1875 the books which had been distributed by the state amounted in value to 2 millions of francs; two years later, however, no trace of books or libraries could be found. In 1890 the question was taken up, and in 1892 the minister of public instruction ordered that in every primary school a library should be established under the care of the schoolmaster. For some years the Government annually granted 120,000 francs, a sum which was raised to 200,000 francs in 1878; for their share

of the expenses the departments contributed in 1875 as much as 170,000 francs. As an instance of the rapidity with which the school libraries have increased, it may be stated that Haute-Marne, which only possessed 44 of them in 1866, ten years later had 548; in 1877 there were about 17,764 *bibliothèques scolaires* possessing 1,716,904 works, and there are now over 20,000 of them in France. The libraries, which are intended not only for the use of school children but also for their parents and other adults, are regulated by a commission sitting at the ministry of public instruction.

#### Germany (with Austria and Switzerland).

Germany is emphatically the home of large libraries; Germany her want of political unity and consequent multiplicity of capitals have had the effect of giving her a considerable number of large state libraries, and the number of her universities has tended to multiply considerable collections.

Berlin is well supplied with libraries, seventy-two being Berlin, registered by Petzholdt in 1875, with about 1,293,030 printed volumes. The largest of them is the Royal Library, which was founded by the "Great Elector" Frederick William, and opened as a public library in a wing of the electoral palace in 1661. From 1699 the library became entitled to a copy of every book published within the royal territories, and it has received many valuable accessions by purchase and otherwise. It is now estimated to contain upwards of 700,000 printed volumes and over 15,000 MSS. The amount yearly expended upon binding and the acquisition of books, &c., is £1800. The catalogues are in manuscript, and include a general alphabetical author catalogue, and a systematic subject-catalogue in a handy form. The building, erected about 1780 by Frederick the Great, has long been too small, and a new one is in contemplation. The conditions as to the use of the collections are, as in most German libraries, very liberal. Any adult person is allowed to have books in the reading-room. Books are lent out to all higher officials, including those holding educational offices in the university, &c., and by guarantee to almost any one recommended by persons of standing; admission to the journal-room is more strictly limited. By special leave of the librarian, books and MSS. may be sent to a scholar at a distance, or, if especially valuable, may be deposited in some public library where he can conveniently use them. There appears to be no limit to the number of books which may be borrowed, although it is prescribed that not more than "three works" must be asked for on one day. Professor Lepsius reports the issues for last year as 71,400 works, to above 5000 readers. The University library (1831) numbers 200,000 volumes with 353 MSS. The number of volumes lent out in 1880 was 40,101. The library possesses the right to receive a copy of every work published in the province of Brandenburg. Some of the governmental libraries are important, especially those of the Military Academy and the General Staff, which was increased in 1872 by acquiring the library of the "École d'Application" at Metz. In 1850 some popular libraries were established by a society for giving scientific lectures. There are now thirteen such libraries with over 54,000 volumes, but the yearly number of readers is only about 12,000.

The libraries of Munich, though not so numerous as those Munich of Berlin, include two of great importance. The Royal Library, the largest collection of books in Germany, was founded by Duke Albrecht V. of Bavaria (1550-79), who made numerous purchases from Italy, and incorporated the libraries of the Nuremberg physician and historian Schedel, of Widmannstadt, and of J. J. Fugger. The number of printed volumes is estimated at about one million, although it is long since any exact enumeration has been made. The library is especially rich in incunabula, many of them being derived from the libraries of the monasteries closed in 1803. The Oriental MSS. are

<sup>1</sup> See De Wattenville, *Rapport sur les Bibliothèques scolaires*, 1879.

numerous and valuable, and include the library of Martin Haug. The amount annually spent upon the library is £5400, of which £2050 is expended upon books and binding. The catalogues of the printed books are in manuscript, and include (1) a general alphabetical catalogue, (2) an alphabetical repertorium of each of the 195 subdivisions of the library, (3) biographical and other subject catalogues. A printed catalogue of the MSS. in 8 volumes is nearly complete; the first was published in 1858. The library is open only twenty-nine hours during the week, while the Royal Library at Berlin is, except in the three winter months, open for thirty-nine. The library of the British Museum is now open for sixty-six hours per week, but it lends no books out. The regulations for the use of the library are very similar to those of the Royal Library at Berlin. The building erected for this collection under King Louis I. in 1832-43 is regarded as a model library structure. The archives are bestowed on the ground floor, and the two upper floors are devoted to the library, which occupies seventy-seven apartments. The University Library was originally founded at Ingolstadt in 1472, and removed with the university to Munich in 1826. It participated in 1803 in the division of the literary treasures of the dissolved monasteries. At present the number of volumes in the general library amounts to 290,000, besides which several special collections are also deposited in the library to the number of 32,800 volumes. The MSS. number 1744. The various libraries of Munich have upwards of 1,400,000 volumes.

Dresden. Dr Petzholdt has registered no less than 49 libraries in Dresden, where indeed his inquiries were likely to be particularly exhaustive. The Royal Public Library in the Japanese Palace was founded in the 16th century. Among its numerous acquisitions have been the library of Count Bismarck in 1764, and the manuscripts of Ebert. Special attention is devoted to history and literature. The library does not claim to possess more than 350,000 vols., although Petzholdt in 1875 reckoned them as at least 500,000 printed books, as well as 100,000 dissertations. The MSS. number 6500 volumes. Admission to the reading-room is granted to a respectable adult on giving his name, and books are lent out to persons qualified by their position or by a suitable guarantee. Here as at other large libraries in Germany, works of belle-lettres are only supplied for a literary purpose. The number of persons using the reading-room in a year is about 3000, and about 10,000 works (and volumes) are lent to about 500 readers. The "Pfinke-Sachsensche" Gentur's Library, now in the possession of Prince George of Saxe-Coburg, and of which Dr Petzholdt, the Nestor of bibliographers, is librarian, is a private library to which access is permitted.

Stuttgart. The Royal Public Library of Stuttgart, although only established in 1765, has grown so rapidly that it now possesses about 42,000 "numbers" of printed works and 3800 MSS. There is a fine collection of Bibles, containing 7200 volumes. The annual expenditure is about £2640, of which £1250 is devoted to books and binding. The library also enjoys the copy-privilege in Württemberg. "The borrowing of books for home use is open to all members of the German empire resident in Stuttgart, whose personal and economic circumstances offer the opportunity, and who, for the safety of the national property. The library may, moreover, be used free of any part of Württemberg on payment of the cost of carriage." The annual number of borrowers is over 1800, who use nearly 17,000 volumes. The number issued in the reading-room is at least twice as great. The number of parcels despatched from Stuttgart is nearly 900. Admission is also gladly granted to the Royal Private Library, founded in 1810, which contains about 50,000 volumes and 600 MSS. The Royal Library of Stuttgart is a

**Darmstadt.** Volumes and 600 MSS. The other libraries of Stuttgart, of which Petzholdt reckons 11, are not of importance. The Grand-ducal Library of Darmstadt was established by the grand duke Louis I. in 1817, on the basis of the still older library formed in the 17th century. The number of volumes used in the course of the year is about 30,000, of which 9000 are lent out to about 5000 readers.

**Gotha.** The Ducal Library of Gotha was established by Duke Ernest the Pious in the 17th century, and contains many valuable books and MSS. from monastic collections. It numbers about 240,000 works, with upwards of 6000 MSS. The catalogue, now in course of publication, of the Oriental MSS., chiefly collected by Seiden, and forming one-half of the collection, is one of the best in existence. Other great Ducal Libraries are noticed in the tables.

Libraries of varying extent and importance are attached to all

the twenty-one universities of Germany, most of them being royal Universities with the universities themselves. Thus the oldest library is that of the University of Halle, which in its earlier form dates from 1566. In 1609 a library, had become so important that Joseph Scaliger wrote of it "*Libra-  
pletior est et nobilior librorum quam Vaticana*". In 1624 the library was carried to Rome as a present to the pope, but one of the treasures were unfortunately lost. The later collection was first formed in 1793. The collection of MSS. is extremely valuable.

The library of Leipzig says its oldest dates from 1099, although it was not until the middle of the 16th century that it was properly organized. The library of Göttingen owes much to the labours of the illustrious Heyne. It and the library of Bonn are complete and best arranged of the German libraries. New buildings for its accommodation are in course of erection. The library at Strasbourg, although founded only in 1572, is complete, though much has been destroyed in the siege, and ranks next to the best libraries of the empire. It holds 188,476 volumes, amounting to 513,000. The remaining universities have not so rich collections.

Some of the towns in the  
were among the earliest to  
The oldest of them is said  
at least as early as 1460.  
imperial city it has had to  
blame at Munich.

The whole notation of the  $\mathcal{G}$  is generated by Dr Petzhold's 1567

A report issued in 1871-74 by the Austrian Statistical Austria Commission, furnishes an account of the condition of the libraries in those portions of Austria which are represented in the Reichsrath, as they were at the end of the year 1870. The number of libraries registered was 577, of which 23, however, were private libraries. Of the rest 159 belonged to religious corporations and seminaries, 105 were military libraries, 56 belonged to literary and scientific societies, 189 were of an educational and scholastic, and the remaining 45 of a public character.

The largest library in Austria, and one of the most important collections in Europe, is the Imperial Public Library at Vienna, apparently founded by the emperor Frederick III. in 1440, although its fictitious librarian Lamberius, in the well known inscription over the entrance to the library which summarizes its history, attributes this honour to Frederick's son Maximilian. However that may be, the munificence of successive emperors gradually added to the wealth of the collection, including a not inconsiderable portion of the dispersed library of Charlemagne. Since 1808 the library has also been entitled to the copy privilege in respect of all books published in the empire. The sum devoted to the purchase of books is £20,000 annually. The main library apartment is one of the most splendid halls in Europe. Admission to the reading room is free to everybody, and books need only be asked under stricter limitations. The University Library of Vienna was established by Maria Theresa. The reading room is open to all comers, and the library is open on longer hours than is the rule with university libraries generally. In winter, for instance, it is open from 5 p.m. in the evening, and it is even open from 9 to 12 on Sundays. In 1879, 159,768 volumes were used in the library, 46,300 volumes lent out in Vienna, and 1418 volumes sent carriage free to borrowers outside Vienna. The total number of libraries

Vienna enumerated by Dr Petzholdt is 101, and many of them are of considerable extent.

[illegible]

The libraries in the Hungarian region were included in the

report, and, as will be seen from the tables, are not very numerous. The most important of them are at Buda-Pest.

**Switzerland.** The public libraries of Switzerland have been very carefully registered by Dr Ernest Heitz, as they existed in 1868. Altogether no less than 2096 libraries are recorded, four-fifths of these belong to the class of "bibliothèques populaires et celles pour la jeunesse," and few are of literary importance. Only eighteen have as many as 30,000 volumes. The largest collection of books in Switzerland is the University Library of Basel, founded with the university in 1460. The monastic libraries of St Gall and Einsiedeln date respectively from the years 830 and 946, and are of great historical and literary interest.

#### ITALY.

**Italy.**

As the former centre of civilization, Italy is of course the country in which the oldest existing libraries must be looked for, and in which the rarest and most valuable MSS. are preserved. The Vatican at Rome and the Laurentian Library at Florence are sufficient in themselves to entitle Italy to rank before most other states in that respect, and the venerable relics at Vercelli, Milan, and La Cava bear witness to the enlightenment of the peninsula in times when other nations were slowly taking their places in the circle of Christian polity. The local rights and interests which so long helped to impede the unification of Italy were useful in creating and preserving at numerous minor centres many libraries which otherwise would probably have been lost during the progress of absorption that results from such centralization as exists in England. In spite of long centuries of suffering and of the aggression of foreign swords and foreign gold, Italy is still rich in books and MSS.; there are probably more books in united Italy than in any other country except France. When the Italian Government published its valuable report on "Biblioteche" in the *Statistica del Regno d'Italia* in 1865, a table of relative statistics was given, which professed to show that, while the number of books in Austria (2,408,000) was greater than the total contents of the public libraries in any one of the countries of Great Britain, Prussia, Bavaria, or Russia, it was surpassed in France (4,382,000) and in Italy (4,142,281), the latter country thus exhibiting a greater proportion of books to inhabitants than any other state in Europe, except only Bavaria. The opulent libraries of Rome and Venice had not yet become Italian, and were not included in the report.<sup>1</sup>

**Public libraries.**

The public libraries (*biblioteche governative*) are under the authority of the minister of public instruction, and are subject to certain regulations finally agreed upon during the ministry of Ugo Ruggiero Bonghi in 1876.<sup>2</sup> They are classed under the headings of (1) national libraries of Florence, Naples, Turin, Palermo, Vittorio Emanuele of Rome, the Brera of Milan, and the Marciana of Venice; (2) the libraries of the universities of the first class—Bologna, Naples, Padua, Pavia, Pisa, and Rome; (3) those of the universities of the second class—Cagliari, Catania, Genoa, Messina, Modena, Parma, and Sassari; (4) those of academies and institutions of fine arts; the last, although under Government control, are ruled by special regulations of their own. Small collections are sometimes handed over to the local authorities, should this be considered desirable, and the state will take into its own hands the administration of provincial or communal libraries if necessary. The librarians and subordinates are divided into (1) prefects, librarians, and sub-librarians; (2) assistant librarians; (3) attendants, or book distributors; (4) ushers, &c. Those

of class 1 constitute the "board of direction," which is presided over by the prefect or librarian, and meets from time to time to consider important measures connected with the administration of the library. The candidates for posts in classes 1 and 2 must possess certain scholastic qualifications and serve for a specified time as *alumni* on probation. An important feature of the regulations consists of the scheme (unfortunately not yet in working order) which is eventually to supply Italy with a body of young librarians properly trained in all the theoretical and technical branches of their profession. Each library is to possess, alike for books and MSS., a general inventory or accessions-catalogue, an alphabetical author-catalogue, and a subject-catalogue. When they are ready, catalogues of the special collections are to be compiled, and these the Government intends to print, together with the subject-catalogues of the MSS. Various other small registers are provided for. The sums granted by the state for library purposes must be applied to (1) salaries and maintenance; (2) binding and repairs; (3) purchase of books, MSS., &c. Books are chosen by a committee nominated by the minister, which, in the national libraries, includes the members of the council of direction. In other libraries two members only of the council form part of the committee. In the university libraries two-fifths of the expenditure is decided by the committee, and the remainder by a council formed by the professors of the different faculties. The rules for lending books and MSS. allow them to be sent to other countries under very special circumstances.

The *biblioteche governative* are now 32 in number, and annually spend about 150,000 lire in books. From the three sources of gifts, copyright, and purchases, their accessions in 1879 were 35,541, being 5187 more than the previous year. The number of readers is now gradually increasing. In 1879 there were 895,749, who made use of 1,151,853 volumes, showing an increase of 10,393 readers and 130,051 books as contrasted with the statistics of the previous year.<sup>3</sup>

The minister of public instruction has kept a watchful eye upon the literary treasures of the suppressed monastic bodies. In 1875 there were 1790 of these confiscated libraries, containing two millions and a half of volumes. About 650 of the collections were added to the contents of the public libraries already in existence; the remaining 1050 were handed over to the different local authorities, and served to form 371 new communal libraries, and in 1876 the number of new libraries so composed was 415.

The Biblioteca Vaticana stands in the very first rank among European libraries as regards antiquity, since from the middle of the 5th century we have evidence of the existence of a pontifical library at Rome; and Pope Zachary (d. 752), himself a Greek, is known to have added considerably to the store of Greek codices. The Lateran Library shared in the removal of the papal court to Avignon, and it was on the return of the popes to Rome that the collection was permanently fixed at the Vatican. Nicholas V. (d. 1455) may, however, be considered the true founder of the library, and is said to have added 5000 MSS. to the original store. Calixtus III. also enriched the library with many volumes saved from the hands of the Turks after the siege of Constantinople. So large a proportion of the printed books of the 15th century having been produced by the Italian presses, it is natural to expect that a great number of specimens may be found in the papal library, and, but for the wholesale destruction of books and MSS. during the sack of Rome by the duke of Bourbon in 1527, the

<sup>1</sup> The *Statistica del Regno d'Italia* gives 210 libraries, of which 164 were open to the public and 46 not. Of the 171 were general and 39 special libraries, the latter including 25 devoted to ascetic theology, 11 to science and literature, and 3 to the fine arts. Tuscany, Sicily, and Emilia were the richest in books, the latter province alone containing one-quarter of the whole number.

<sup>2</sup> See the "Regulations of Italian Public Libraries," by Count Ugo Balzani, *Library Journal*, iv. pp. 183-87.

<sup>3</sup> Lists of foreign accessions to the *biblioteche governative* are published by the minister of public instruction from time to time. In 1877 E. Narducci made proposals for a general catalogue of their contents, and issued a specimen of *Boccaccio*.

Vatican Library would have been as rich in early printed literature as it is now rich in manuscripts. Sixtus V. erected the present building in 1588, and considerably augmented the collection. Gregory XV. received as a gift from Maximilian, duke of Bavaria, the library of the elector Palatine seized by Tilly at the capture of Heidelberg in 1622. The greater part of the library at Urbino, founded by Duke Federigo, was acquired in 1655 by Alexander VII. for the sum of 10,000 scudi, and some of the famous palimpsests from the Benedictine monastery of Bobbio were also added to the treasures of the Vatican. After the death of Christina, queen of Sweden, her collection of books and manuscripts, formed from the plunder seized at Prague, Würzburg, and Bremen by her father Gustavus Adolphus, became by succession the property of the Ottoboni family, the head of which, Alexander VIII., in 1689 placed 1900 of the MSS. in one of the galleries. Clement VII. and Pius II. also enriched the Vatican with valuable manuscripts, including many Oriental. In 1740 Benedict XIV. united with it the Ottoboniana, and in the same pontificate the Marchese Aless. Capponi bequeathed his precious collections. Clement XIII. in 1758, Clement XIV. in 1769, and Pius VI. in 1775 were also important benefactors. For over two hundred years the history of the Vatican was one of unbroken prosperity, but it suffered a serious blow at the close of the 18th century, when MSS. dating before the 9th century, and the most choice artistic specimens, altogether to the number of 500, were carried off by the French to Paris in 1798. The greater part were, however, restored in 1815, and most of the Palatine MSS., which formed part of the plunder, ultimately found their way to the university of Heidelberg in 1816. Pius VII. acquired for the Vatican the library of Cardinal Zelada in 1800; Leo XII. was able to add the noble collection of fine art literature of Count Cicognara in 1823; and Gregory XVI. also largely augmented the library. Pius IX. in 1856 added 40,000 volumes belonging to Cardinal Mai.

Few libraries are so magnificently housed as the Biblioteca Vaticana. The famous *Codici Vaticani* are placed in the *salone* or great double hall, which is decorated with frescos depicting ancient libraries and councils of the church. At the end of the great hall an immense gallery, also richly decorated, and extending to 1200 feet, opens out from right to left. Here are preserved in different rooms the *codici Palatini*, *Regin.*, *Ottoboniani*, *Capponiani*, &c. Most of the printed books are contained in a series of six chambers known as the *Appartamento Borghese*. The printed books only are on open shelves, the MSS. being preserved in closed cases.

The present official estimate of the number of printed volumes is about 220,000, including 2500 15th century editions, of which many are vellum copies, 500 Aldines, and a great number of bibliographical rarities.<sup>1</sup> There are 25,600 MSS., of which 19,641 are Latin, 3613 Greek, 609 Hebrew, 900 Arabic, 460 Syriac, 78 Coptic, &c. Among the Greek and Latin MSS. are some of the most valuable in the world, alike for antiquity and intrinsic importance. It is sufficient to mention the famous Biblical *Codex Vaticanus* of the 4th century, the *Virgil* of the 4th or 5th century, the *Terence* equally ancient, the palimpsest *De Republica* of Cicero, conjectured to be of the 3d century, discovered by Cardinal Mai, and an immense number of richly ornamented codices of extraordinary beauty and costliness. The archives are apart from the library, and are quite inaccessible to the public; no catalogue is known to exist. Leo XII. has appointed a committee to consider what documents of general interest may expediently

be published, and a greater liberality in the use of them is said to be contemplated.

The Biblioteca Vaticana is now open from 8 to 12 every morning between November and June, with the exception of Sundays, Thursdays, and the principal feast days. Permission to study is obtained from the cardinal secretary of state. The want of proper catalogues for the use of readers is a great drawback. There are imperfect written lists (for the use of the librarians alone) of the printed books, and various catalogues of special classes of the MSS. have been published. New catalogues, however, are in course of preparation. The Oriental MSS. have been described by J. S. Assemani, *Bibliotheca orientalis Clementina-Vaticana*, Rome, 1719-28, 4 vols. folio, and *Bibl. Vat. compl. MSS. catalogus ab S. E. et J. S. Assemanio collectus*, ib., 1756-59, 3 vols. folio, and by Cardinal Mai in *Script. Vet. novæ collectio*. The Coptic MSS. have been specially treated by G. Zoega, Rome, 1810, folio; and by F. G. Boujour, Rome, 1699, 4to. There are printed catalogues of the Capponi (1747) and the Cicognara (1820) libraries.

Next in importance to the Vatican library is the Casanatense, Other so called from the name of its founder, Cardinal Casanata (1700). Roman libraries. It contains about 130,000 volumes of printed books, including a large number of 15th century impressions, and early editions with woodcuts, as well as about 2500 MSS., of which are one of the 7th century and several of the 8th, 9th, and 10th centuries. They are carefully arranged in eleven rooms, the largest central hall being one of the finest in Rome. Books are not allowed to be taken out of the reading-rooms, but admission is only granted, and the annual number of readers is about 18,000. The subscription is a small one, but additions continue to be made, and the library well administered. All the officials, in accordance with the founder's will, belong to the Dominican order. The incomplete catalogue of the printed books, prepared by A. Audiffrédi, Rome, 1761-88, 4 vols. folio, still remains a model of cataloguing. Vittorio Emanuele forms part of the Collection of the Casanatense, made up from the old Jesuit library, and a number of other suppressed institutions. It contains 360,000 volumes, with 5000 MSS., and is entered by a bridge. The entire collection comprises a million of volumes, besides the *Kinder* and other which are already catalogued. The *Bibliotheca Angelica* contains all the authentic acts of the Congregation of the Precious Collections of Cardinal Passionei and his successors. The *Bibliotheca Alessandrina della R. Università di Roma*, founded by Alexander VII., is considerably used by scholars in 1879 57,000 readers. The greater part of the formerly in the collection of the duke of Tiroli library.<sup>2</sup> The *Bibliotheca del Senato* is a valuable municipal history and statutes of Padua. The printed catalogue (1878) describes no less than 190,000 volumes, containing them, relating to 143 localities. The *Bibliotheca Vallicelliana* was founded by Filippo Vallicella, and contains some valuable manuscripts, including the *Manuscript* of the 15th century attributed to Albin, and some medietated with the *Manuscript*. In 1877 Professor A. Sarti presented to the city of Rome a collection of fine-art books, 10,000 volumes, which were in charge of the Accademia di San Luca, which already possessed a good artistic library. Of private libraries accessible by permission, we note the *Bibliotheca Barberina*, including many rare books, with valuable autographs, but especially remarkable for its MSS.; these were chiefly collected by Cardinal Fr. Barberini, the nephew of Urban VIII., and comprised the *Manuscript* of Galil. Galilei, and Bellarmine, the reports on the state of Catholicism in England in the time of Charles I., and a quantity of medietated materials for the history of the Stuarts. A catalogue was published at Rome in 1681, 3 vols. folio. The *Casimira* founded by Clement XII. (Lorenzo Casimira is also a private library, it is rich in rare books, and includes one of the most remarkable collections of prints in Italy, the series of Marc Antoine being especially complete. The library of the Collegium de Propaganda Fide was founded by Urban VIII. in 1626, and in 1857 the cardinal Antonio Brancati obtained permission to preserve in it prohibited books.

<sup>1</sup> See *Cicognara Roma*, *Discorso di Ruggiero Bonghi*, &c.

<sup>2</sup> Signor F. Narducci produced a catalogue of the MSS. Oriental in 1877. The Casanatense, Vitt. Emanuele, and Alessandrina are Governmental, and in 1878 the municipal instruction published a catalogue of the Oriental MSS. the three last. The Oriental MSS. of the other *bibliothecæ* generally will be treated in subsequent volumes.

<sup>1</sup> The books have never been actually counted, and this estimate has been reduced by some persons to half the number.

destroyed by the French army in 1798, and owes its present richness almost entirely to testamentary gifts, among which may be mentioned those of Cardinals Borghia, Caleppi, and Pietro. It is a private collection for the use of the congregation and of those who belong to it, but permission may be obtained from the superiors. There are at least thirty libraries in Rome which are more or less accessible to the public. One is now in course of formation which will include everything relating to the emancipation of Italy.

**Subiaco.** At Subiaco, a few miles from Rome, the library of the Benedictine monastery of Santa Scolastica is not a very large one, comprising only 6000 printed volumes and 400 MSS., but the place is remarkable as having been the first seat of typography in Italy. It was in this monastery that Schweynheim and Pannartz, fresh from the dispersion of Fust and Schoeller's workmen in 1462, established their press and produced a series of very rare and important works which are highly prized throughout Europe. The Subiaco Library, although open daily to readers, is only visited by students who are curious to behold the cradle of the press in Italy, and to inspect the series of original editions preserved in their first home.

**National libraries.** The great national libraries are as follows:

**Florence.** The Biblioteca Nazionale of Florence, formed from the union of Magliabechi's library with the Palatina, is the largest in Italy. The Magliabechi collection became public property at his death in 1714, and, with the accessions made from time to time, held an independent place until 1862, when the Biblioteca Palatina (formed in 1815 from the old Pitti Library and the collections of Poggiali and Racuszky) was incorporated with it. An old statute by which a copy of every work printed in Tuscany was to be presented to the Magliabechi Library was formerly much neglected, but has been maintained rigorously in force since 1860. There are many valuable autograph originals of famous works in this library, and the MSS. include the most important extant *codici* of Dante and later poets, as well as of the historians from Villani to Machiavelli and Guicciardini. Amongst the printed books is a very large assemblage of rare early impressions, a great number of the *Rappresentazioni* of the 16th century, at least 200 books printed on vellum, and a copious collection of municipal histories and statutes, of *testi di lingua*, and of geographical and topographical maps. The MS. portolani, 25 in number, are for the most part of great importance; the oldest is dated 1417, and several seem to be the original charts executed to Sir Robert Dudley (duke of Northumberland) in the preparation of his *Arcano del Mare*. The annual increment of books in this library is about 12,000. It is open freely to the public, and about 50,000 readers annually make use of it. About 60,000 printed volumes and 2500 MSS. are consulted annually, not including some 1500 books and 50 MSS., which are lent out yearly to certain students.—The Biblioteca Nazionale at Naples, though only opened to the public in 1804, is the largest library of that city. The nucleus from which it developed was the collection of Cardinal Serpando, which comprised many MSS. and printed books of great value. Acquisitions came in from other sources, especially when in the year 1848 many private and conventual libraries were thrown on the Neapolitan market.<sup>1</sup> The Biblical section is rich in rarities, commencing with the Mainz Bible of 1462, printed on vellum. Other special features are the collection of *testi di lingua*, that of books on volcanoes and that of works printed at famous presses, particularly those executed by the typographers of Naples. The MSS. include a palimpsest containing writings of the 3d, 5th, and 6th centuries under a grammatical treatise of the 8th, 2 Latin papyri of the 6th century, over 50 Latin Bibles, and a great number of illuminated books with miniatures. There are more than 40 books printed on vellum in the 15th and 16th centuries, including a fine first Homer. There are several MS. maps and portolani, one of them dating from the end of the 14th century. About 10,000 readers use this library, consulting some 140,000 books yearly. The

**Milan.** The Biblioteca Nazionale of Milan, better known as the Beza, founded in 1770 by a decree of the empress Maria Theresa, consists of 163,123 printed volumes and 2646 MSS., with a yearly increment of about 6000 volumes, and the annual number of readers is said to amount to 45,000. It comprises nearly 2500 books printed in the 15th century including the rare *Mondo Sinto di Dio* of Bettini, 1477, 913 Aldine impressions, and a xylographic *Bibbia Pauperum*. Amongst the MSS. are an early Dante and autograph letters of Götter, some poet. The library also contains a fine collection of illustrated service-books, with miniatures representing the advance of Italian art from the 12th to the 16th century. These were formerly

**Palermo.** in the Certosa at Pavia. The Biblioteca Nazionale of Palermo, founded from the Collegio Massimo of the Jesuits, with additions from other libraries of that suppressed order, is rich in 15th century book, which have been elaborately described in a catalogue printed in 1875, and in Aldines and bibliographical curiosities of the 16th and following centuries.—The Biblioteca

**Turin.** Nazionale of Turin is extensively used by readers, whose annual

number amounts to 120,000. The majority of the books are works for scientific study, but amongst them are several rarities, comprising a Sedulius MS. of the 5th century, the celebrated MS. of the *De Imitatione* (on which the assignment of its authorship to Gersen is founded,—see KEMPS), and several productions of the earliest German and Italian printers.—The Biblioteca Marciana, or library of St Mark at Venice, was founded Venice. in 1362 by a donation of MSS. from the famous Petrarch (most of them now lost), and instituted as a library by Cardinal Bessarion in the 15th century. It is open daily, and is used by about 40,000 readers annually. The precious contents include Greek MSS. of great value, of which more than 1000 were given by Cardinal Bessarion, important MS. collections of works on Venetian history, rare incunabula, and a great number of volumes, unique or exceedingly rare, on the subject of early geographical research. Amongst the MSS. is a Latin Homer in the autograph of Boccaccio, an invaluable codex of the laws of the Lombards, and the autograph MS. of Sarpi's *History of the Council of Trent*. Since the fall of the republic and the suppression of the monasteries afterwards, a great many private and conventual libraries have been incorporated with the Marciana.

Of the university libraries under Government control it is Univer- sufficient to notice the Biblioteca della Università at Bologna, sity founded in 1712, by Count Luigi F. Marsighi or Marsili. The libraries. MSS. comprise a rich Oriental collection of 547 MSS. in Arabic, 173 in Turkish, and several in Persian, Armenian, and Hebrew. Amongst the Latin codices is a Lactantius of the 6th or 7th century. The other noteworthy articles include a copy of the Armenian gospels (12th century), the Avicenna, with miniatures dated 1194, described in Montfaucon's *Diarium Italicum*, and some unpublished Greek texts. Amongst the Italian MSS. is a rich assemblage of municipal histories. Mezzofanti was for a long time the custodian here, and his own collection of books has been incorporated in the library, which is remarkable likewise for the number of early editions and Aldines which it contains. It possesses the Mainz Latin Bible dated 1462; the Lactantius and Augustine *De Civitate Dei* printed by Schweynheim and Pannartz, the Foligno Dante of 1472, and a copy of Henry VIII.'s *Assertio Sacramentorum* with the royal author's autograph. A collection of drawings by Agostino Caracci is another special feature of worth. The Manfredi palace, in which the library is arranged, is a fine building begun in 1714 and finished in 1744. The grand hall with its fine furniture in walnut wood merits particular attention. The library is open to the public; the yearly number of readers is about 25,000, and of books consulted 40,000.<sup>2</sup>

Of the remaining Government libraries the following may be named. The Biblioteca del Monastero della S. Trinità, at La Cava. La Cava dei Tirreni in the province of Salerno, is after the Biblioteca dell' Archivio Capitolare at Vercelli the most ancient library in the Italian kingdom, its foundation being said to be contemporaneous with that of the Benedictine abbey itself (beginning of the 11th century). It only contains some 10,000 volumes, but these include a number of MSS. of very great rarity and value, ranging from the 8th to the 14th century. Amongst these is the celebrated Codex Legum Longobardorum, dated 1004, besides a well-known geographical chart of the 12th century, over 100 Greek MSS., and about 1000 charters beginning with the year 840, more than 200 of which belong to the Lombard and Norman periods.—At Florence the Marucelli Library, founded in 1752, is remarkable for its artistic wealth of early woodcuts and metal engravings. The number of these and of original drawings by the old masters amounts to 80,000 pieces.—At Modena is the famous Biblioteca Palatina, sometimes called Modena. the Biblioteca Estense from having been founded by the Este family at Ferrara in 1393; it was transferred to Modena by Cesare D'Este in 1598. Muratori, Zaccaria, and Tiraboschi were librarians here, and made good use of the treasures of the library. It is particularly rich in early printed literature and valuable codices. The oldest library at Naples is the Biblioteca Brancacciana, with many valuable MSS. relating to the history of Naples. Two planispheres by Coronelli are preserved here. It was founded in 1673 by Cardinal F. M. Brancaccio.—The Regia Biblioteca di Parma, founded definitively in 1779, owes its origin Parma. to the grand-duke Philip, who employed the famous scholar Paciadani to organize it. It is now a public library containing 213,995 volumes, including 4000 MSS., with an annual increment of nearly 1000 volumes. Amongst its treasures is De Rossi's magnificent collection of Biblical and rabbinical MSS.

Chief among the great libraries not under Government control comes the world-famed Biblioteca Mediceo-Laurenziana at Florence, founded from the collections of Cosimo the Elder, Pietro de' Medici, and Lorenzo the Magnificent (which, however, passed away from the family after the expulsion of the Medici from Florence, and were repurchased by Cardinal Giovanni afterwards Leo X.). It was first constituted as a public library in Florence by

<sup>1</sup> A pamphlet by the present chief librarian, Vito Fornari, Naples, 1874, gives many useful details, although he there overstates the number of MSS. as 10,000 (there may be some confusion between volumes and works).

<sup>2</sup> Notices of other libraries of this class will be found in the tables.

Clement VII., who charged Michelangelo to construct a suitable edifice for its reception. It was opened to the public by Cosimo I. in 1571, and has ever since gone on increasing in value, the accessions in the 18th century alone being enough to double its former importance. The printed books it contains are probably no more than 3000 in number, but are almost all of the highest rarity and interest. It is, however, the precious collection of MSS., amounting to about 7000 articles, which gives its chief importance to this library. They comprise some of the most valuable codices in the world,—the famous Virgil of the 4th or 5th century, Justinian's *Pandects* of the 7th, a Homer of the 10th, and several other very early Greek and Latin classical and Biblical texts, as well as copies in the handwriting of Petrarch, about 100 codices of Dante, a *Decameron* copied by a contemporary from Boccaccio's own MS., and Collini's MS. of his autobiography. Bandini's catalogue of the MSS. occupies 13 vols. folio, printed in 1764 78.—At Genoa the Biblioteca Franzoniana, founded about 1770 for the instruction of the poorer classes, is noteworthy as being the first European library lighted up at night for the use of readers.—The famous Biblioteca Ambrosiana at Milan was founded in 1609 by Cardinal Fed. Borromeo. It contains 164,000 printed volumes and 8100 MSS. Amongst the MSS. are a Greek Pentateuch of the 5th century, the famous Peshito and Syro-Hexaplar from the Nitrian convent of St. Maria Deipara, a Josephus written on papyrus, supposed to be of the 5th century, several palimpsest texts, including an early Plautus, and St. Jerome's commentary on the Psalms in a volume of 7th century execution, full of contemporary glosses in Irish, Gothic fragments of Ulfilas, and a Virgil with notes in Petrarch's handwriting.<sup>1</sup> Noteworthy amongst the printed books is Valdarfer's Boccaccio of 1471, as well as the Virgil of 1470 (Venice), and the editio princeps of Isocrates, both printed on vellum. Cardinal Mai was formerly custodian here. In 1879 Professor C. Monsinger presented his "Biblioteca Europea," consisting of 2500 volumes, 300 maps, and 5000 pieces, all relating to the literature and histories of European countries.<sup>2</sup> The Melzi and Trivulzio libraries should not pass without mention here, although they are private and inaccessible without special permission. The former is remarkable for its collection of early editions with engravings, including the Dante of 1481, with twenty designs by Baccio Bandinelli. The latter is rich in MSS. with miniatures of the finest and rarest kind, and in printed books of which many are unique or nearly so. It consists of 70,000 printed volumes.—The foundation of the monastery of Monte Cassino is due to St. Benedict, who arrived there in the year 529, and established the prototype of all similar institutions in western Europe. He brought with him a few manuscripts, four or five of which are still to be seen. The library of printed books now extends to about 20,000 volumes, chiefly relating to the theological sciences, but including some rare editions. A collection of the books belonging to the monks is in course of formation; it contains about the same number of volumes. But the chief glory of Monte Cassino consists of the *archivio*, which is quite apart; and this includes 30,000 or 40,000 bulls, diplomas, charters, and other documents, besides 1000 MSS. dating from the 6th century downwards. The latter comprehend some very early Bibles and important codices of patristic and other mediæval writings. There are good written catalogues, and a calendar is now being published, *Bibliotheca Cassinensis*, of which 4 volumes have appeared. These libraries enjoy no special revenues, and owe their accessions entirely to donations.—At Ravenna the Biblioteca Classense has a 10th century codex of Aristophanes and two 11th century codices of Dante. Here are also the autograph correspondence of Muratori, and many unpublished letters of modern writers.—At Vercelli the Biblioteca dell' Archivio Capitolare, the foundation of which can be assigned to no certain date, but must be referred to the early days when the barbarous conquerors of Italy had become Christianized, comprises nothing but MSS., all of great antiquity and value. Amongst them is an Evangelium S. Eusebii in Latin, supposed to be of the 4th century; also the famous codex containing the Anglo-Saxon homilies which have been published by the Ælfrie Society.—The "Frari" at Venice contains an enormous collection of archives, the invaluable state paper records of the Venetian republic.

Not a few of the communal and municipal libraries, as will be seen from the tables, are of great extent and interest.

#### Belgium and Holland.

**Brussels.** The national library of Belgium is the Bibliothèque Royale at Brussels, of which the basis may be said to consist of the famous Bibliothèque des Ducs de Bourgogne, the library of the Austrian sovereigns of the Low Countries, which had gradually accumulated

during three centuries.<sup>3</sup> After suffering many losses from thieves and fire, in 1772 the Bibliothèque de Bourgogne received considerable augmentations from the libraries of the suppressed order of Jesuits, and was thrown open to the public. On the occupation of Brussels by the French in 1794 a number of books and MSS. were confiscated and transferred to Paris (whence the majority were returned in 1815); in 1795 the remainder were formed into a public library under the care of La Serna Santander, who was also town librarian, and who was followed by Van Hulthem. At the end of the administration of Van Hulthem a large part of the precious collections of the Bollandists was acquired. In 1830 the Bibliothèque de Bourgogne was added to the state archives, and the whole made available for students. Van Hulthem died in 1832, leaving one of the most important private libraries in Europe, described by Voisin in *Bibliotheca Holbœmiana*, Bruss., 1836, 5 vols., and extending to 60,000 printed volumes and 1016 MSS., mostly relating to Belgian history. The collection was purchased by the Government in 1837, and, having been added to the Bibliothèque de Bourgogne open since 1772, and the Bibliothèque de la Ville (open since 1794), formed what has since been known as the Bibliothèque Royale de Belgique. The printed volumes now number 350,000, with 30,000 MSS., 100,000 prints, and 50,000 coins and medals. The yearly additions to the books amount to between 1500 and 3000; the other departments receive few accessions. The special collections, each with a printed catalogue, consist of the Fonds van Hulthem, for natural history; the Fonds Fétis, for music; the Fonds Goethals, for zoology; and the Fonds Muller, for physiology. The catalogue of the MSS. has been partly printed, but in an imperfect manner.

The University Library of Ghent, known successively as the Ghent. Bibliothèque de l'École Centrale and Bibliothèque Publique de la Ville, was founded upon the old libraries of the Council of Flanders, of the College des Echevins, and of many suppressed religious communities. It was declared public in 1797, and formally opened in 1798. On the foundation of the university in 1817 the town placed the collection at its disposal, and the library has since remained under state control. The printed volumes now amount to 250,000, with 1600 MSS.; the annual increment is about 2500 volumes. There are important special collections on archaeology, Netherlands literature, national history, books printed in Flanders, and 25,000 historical pamphlets of the 16th and 17th centuries. There are printed catalogues of the works on jurisprudence of 1830, and of the MSS. (1852).—The Bibliothèque de l'Université Catholique de Louvain is based upon the collection of Bayardick, who bequeathed it to his alma mater in 1627; this example was followed by Jacques Romain, professor of medicine, but the proper organization of the library commenced in 1636. There are now said to be 250,000 volumes. The Bibliothèque de l'Université of Liège dates from 1817, when on the foundation of the university the old Bibliothèque de la Ville was added to it. There are now 195,746 printed volumes, 87,254 pamphlets, 1544 MSS., and 142 medals. The Liège collection (of which a printed catalogue appeared in 3 vols. 8vo, 1872), bequeathed by M. Ulysse Caplaine, extends to 12,061 volumes and pamphlets. A printed catalogue of the medical books was published in 1844, and one of the MSS. in 1850.

The national library of Holland is the Koninklijke Bibliotheek The Hague, which was established in 1798, when it was decided to join the library of the princes of Orange with those of the different Government bodies in order to form a library for the State General, to be called the National Bibliotheek. In 1805 the present name was adopted, and since 1815 it has become the national library. In 1818 the Baron W. Y. H. van Westrich van Tielandt bequeathed his valuable books, MSS., coins, and antiquities to the country, and directed that they should be preserved in his former residence as a branch of the royal library. There are now upwards of 200,000 volumes of printed books, with an annual increment of 4000 volumes. The MSS. number 4000, chiefly historical, but including many fine books of hours with miniatures. Books are lent all over the country. Some twenty-five years ago it was decided for economical reasons to restrict the purchases to political, historical, and legal works, but recently, in consequence of an increase in the yearly subsidy, literature has been added to these three classes. The library boasts of the richest collection in the world of books on chess, Dutch meubels, Ekevis, and Spinoza. There is one general written catalogue arranged in classes with alphabetical indices. In 1800 a printed catalogue was issued, with four supplements down to 1811; and since 1866 a yearly list of additions has been published. Special mention should be made of the excellent catalogue of the incunabula published in 1850.

The next library in numerical importance is the famous Bibliotheca Academica Lugduno-Batava, which dates from the foundation of the university of Leyden by William I., prince of Orange, on February 8, 1575. It has acquired many valuable additions from the books and MSS. of the distinguished scholars, Grotius, Joseph

<sup>1</sup> Coriani has published many of the unique treasures of this collection in his *Monumenta Sacra et Profana*.

<sup>2</sup> This, as well as the Brera library, is exhaustively described in *Gli Istituti accademici, letterari, ed artistici di Milano*, published by the Società Storica Lombarda in 1880; a special treatise on the Brera was published in 1873 by the librarian G. Sacchi. See also Boccia, *De origine et statu Bibliothecæ Ambrosianæ*, 1872.

<sup>3</sup> A most interesting account of the history of this library is to be read in the introduction to *Catalogue des MSS. de la bibliothèque royale des Ducs de Bourgogne*, by M. Marchal, Brussels, 1849, 3 vols. 4to.

Scaliger, Isaac Voss, Ruhnken, and Hemsterhuis. The MSS. comprehend many of great intrinsic importance; the Oriental codices number 2400. The library of the Society of Netherland Literature has been placed here since 1877; this is rich in the national history and literature. The Arabic and Oriental MSS. known as the Legatum Warnerianum are of great value and interest; and the collection of maps bequeathed in 1870 by J. J. Bodel Nyenhuis is also noteworthy. The library is contained in a building which was formerly a church of the Béguines, adapted in 1860 somewhat after the style of the British Museum. The catalogues (one alphabetical and one classified) are on slips, the titles being printed. A catalogue of books and MSS. was printed in 1716, one of books added between 1814 and 1847 in 1848, and a supplementary part of MSS. only in 1850. A catalogue of the Oriental MSS. was published in 6 vols., 1851-77.

**Utrecht.** The University Library at Utrecht dates from 1582, when certain conventual collections were brought together in order to form a public library, which was shortly afterwards enriched by the books bequeathed by Hub. Buchelius and Ev. Pollio. Upon the foundation of the university in 1636, the town library passed into its charge. Among the MSS. are some interesting cloister MSS. and the famous "Utrecht Psalter," which contains the oldest text of the Athanasian creed. The last edition of the catalogue was in 2 vols. folio, 1834, with supplement in 1845, index from 1845-55 in 8vo, and additions 1856-70, 2 vols. 8vo. The titles of accessions are now printed in sheets and pasted down for insertion.

**Amsterdam.** The basis of the University Library at Amsterdam consists of a collection of books brought together in the 15th century and preserved in the Nieuwe Kerk. At the time of the Reformation in 1578 they became the property of the city, but remained in the Nieuwe Kerk for the use of the public till 1632, when they were transferred to the Athenaeum. Since 1877 the collection has been known as the University Library, and in 1881 it was removed to a building designed upon the plan of the new library and reading-room of the British Museum. The library includes the best collection of medical works in Holland, and the Bibliotheca Rosenthaliana of Hebrew and Talmudic literature is of great fame and value; a catalogue of the last was printed in 1875. The libraries of the Dutch Geographical and other societies are preserved here. A general printed catalogue was issued in 6 vols. 8vo, Amsterdam, 1856-77; one describing the bequests of J. de Boach Kemper, E. J. Potgieter, and F. W. Rive, in 3 vols. 8vo, 1878-79; a catalogue of the MSS. of Professor Moll was published in 1880, and one of those of P. Camper in 1881.

#### Denmark, Norway, and Sweden.

**Copenhagen.** The commencement of the admirably managed national library of Denmark, the great Royal Library at Copenhagen, may be said to have taken place during the reign of Christian III. (1533-59), who took pride in importing foreign books and choice MSS.; but the true founder was Frederick III. (1648-70); to him is mainly due the famous collection of Icelandic literature and the acquisition of Tycho Brahe's MSS. The present building (in the Christiansborg Castle) was commenced in 1667. Among notable accessions may be mentioned the collections of C. Reitzler, the count of Danneberg (5000 volumes and 500 MSS.), and Count de Thott; the last bequeathed 6039 volumes printed before 1531, and the remainder of his books, over 100,000 volumes, were eventually purchased. In 1793 the library was opened to the public, and it has since remained under state control. Two copies of every book published within the kingdom must be deposited here. The incunabula and block books form an important series. There is a general classified catalogue in writing in 295 folio volumes for the use of readers; and an alphabetical one on slips arranged in boxes for the officials. A good catalogue of the De Thott collection was printed in 12 vols. 8vo, 1789-95; a catalogue of the French MSS. appeared in 1844; of Oriental MSS., 1846; of the Danish collection, 1875, 8vo. Annual reports and accounts of notable MSS. have been published since 1864. There were 7000 additions in 1880.

The University Library, founded in 1482, was destroyed by fire in 1728, and re-established shortly afterwards. A copy of every Danish publication must be deposited here. The MSS. include the famous Arne-Magne collection (see vol. xii. p. 626).

**Christiania.** The chief library in Norway is the University Library at Christiania, established at the same time as the university, September 2, 1811, by Frederick II., with a donation from the king of many thousands of duplicates from the Royal Library at Copenhagen, and since augmented by important bequests.

**Stockholm.** The Royal Library at Stockholm was first established in 1585. The original collection was given to the university of Upsala by Gustavus II., that formed by Christina is at the Vatican, and the library brought together by Charles X. was destroyed by fire in 1697. The present library was organized shortly afterwards. The Benzeltjerna-Engeström Library (14,500 printed volumes and 1200 MSS., rich in materials for Swedish history) is now annexed to it. Natural history, medicine, and mathematics are left to other

libraries. Among the MSS. the *Codex Aureus* of the 6th or 7th century, with its interesting Anglo-Saxon inscription, is particularly noteworthy. The catalogues are in writing, and are both alphabetical and classified; printed catalogues have been issued of portions of the MSS. The present building was opened in 1882.

The University Library at Upsala was founded by Gustavus Upsala, Adolphus in 1620, from the remains of several convent libraries; he also provided an endowment. The MSS. chiefly relate to the history of the country, but include the *Codex Argenteus*, containing the Gothic gospels of Ulfilas. The general catalogue is in writing. A catalogue was printed in 1814; special lists of the foreign accessions have been published each year from 1850; the Arabic, Persian, and Turkish MSS. are described by C. J. Tornberg, 1846. The library at Lund dates from the foundation of the university in 1668, and was based upon the old cathedral library. The MSS. include the De la Gardie archives, acquired in 1848.

#### Spain and Portugal.

The chief library in Spain is the Biblioteca Nacional (formerly Madrid, the Biblioteca Real) at Madrid. The printed volumes number 400,000 volumes, with 200,000 pamphlets; the accessions in 1880 amounted to 25,840 articles. Spanish literature is of course well represented, and, in consequence of the numerous accessions from the libraries of the suppressed convents, the classes of theology, canon law, history, &c., are particularly complete. The number of bibliographical rarities was largely increased by the incorporation of the valuable collection formed by the well-known bibliographer Don Luis de Usóz. There are 30,000 MSS., contained in 10,000 volumes and bundles; they include some finely illuminated codices, historical documents, and many valuable autographs. The collection of prints extends to 120,000 pieces, and was principally formed from the important series bought from Don Valentin Cardenera in 1865. In 1880 54,875 books were issued to 51,966 readers. The annual revenue is only £1600. The printed books have one catalogue arranged under authors' names, and one under titles; the departments of music, maps and charts, and prints have subject-catalogues as well. There is a general index of the MSS., with special catalogues of the Greek and Latin codices and genealogical documents. The first (and only) volume of a printed catalogue of the Greek MSS. appeared in 1769. The cabinet of medals is most valuable and well arranged. Of the other Madrid libraries (see the tables) it is enough to mention the Biblioteca de la Academia de la Historia (20,000 volumes and 1500 MSS.), which contains some printed and MS. Spanish books of great value, including the well-known Salazar collection.—The history of the library of the Escorial has been given at vol. viii. p. 541. In 1808, before the invasion, the Escorial is estimated to have contained 30,000 printed volumes and 3400 MSS.; Joseph removed the collection to Madrid, but when it was returned by Ferdinand 10,000 volumes were missing. There are now 32,142 printed volumes, with 583 Greek, 1905 Arabic, 73 Hebrew, and 2050 Latin MSS. The Arabic MSS. have been described by M. Casiri, 1760-70; and a catalogue of the Greek codices by Müller was issued at the expense of the French Government in 1848. There is an imperfect written catalogue of the printed books, and the present librarian is now engaged upon a catalogue of the Latin MSS. Permission to study at the Escorial, which is one of the royal private libraries, must be obtained by special application.<sup>1</sup>

Among the libraries of Portugal the Bibliotheca Nacional at Lisbon naturally takes the first place. In 1841 it was largely increased from the monastic collections, which, however, seem to have been little cared for according to a report prepared by the principal librarian three years later. There are now said to be 200,000 volumes of printed books, among which theology, canon law, history, and Portuguese and Spanish literature largely predominate. The MSS. number 9415, including many of great value. There is also a cabinet of 40,000 coins and medals.—The Bibliotheca da Academia, founded in 1780, is preserved in the suppressed convent of the Ordem Terceira da Penitencia. In 1836 the Academy acquired the library of that convent, numbering 30,000 volumes, which have since been kept apart. The Archivo Nacional, in the same building, contains the archives of the kingdom, brought here after the destruction of the Torre do Castello during the great earthquake.

The Bibliotheca Publica Municipal at Oporto is the second largest in Portugal, although only dating from July 9, 1833, the anniversary of the debarkation of D. Pedro, and when the memorable siege was still in progress; from that date to 1874 it was styled the Real Bibliotheca do Porto. The regent (ex-emperor of Brazil) gave to the town the libraries of the suppressed convents in the northern provinces, the municipality undertaking to defray the expense of keeping up the collection, but only £180 is yearly spent on books and bindings, and £380 on salaries. Recent accessions consist

<sup>1</sup> Gachard, *Les bibliothèques de Madrid et de l'Escorial; notices et extraits des MSS. qui concernent l'histoire de Belgique, Bruxelles, 1876, &c.*; Ch. Graux, *Essai sur les origines du fonds grec de l'Escorial*.

mainly of Portuguese and French books. The important Camoens collection is described in a printed catalogue, Oporto, 1880. A notice of the MSS. may be found in *Catalogo dos MSS. da B. Publica Florense*, by H. da Cunha Rivara, Lisbon, 1860-70, 3 vols. folio, and the first part of an *Indice preparatorio do Catalogo dos Manuscriptos* was produced in 1880.

Russia.

**St Petersburg.** The Imperial Public Library at St Petersburg is the third largest library in the world, and now claims to possess 1,000,000 printed volumes. The commencement of this magnificent collection may be said to have been the books seized by the Czar Peter during his invasion of Courland in 1714; the library did not receive any notable augmentation, however, till the year 1795, when, by the acquisition of the famous Zaluski collection, the Imperial Library suddenly attained a place in the first rank among great European libraries. The Zaluski Library was formed by the Polish count Joseph Zaluski, who collected at his own expense during forty-three years no less than 200,000 volumes, which were added to by his brother Andrew, bishop of Cracow, by whom in 1747 the library was thrown open to the public. At his death it was left under the control of the Jesuit College at Warsaw; on the suppression of the order it was taken care of by the Commission of Education; and finally in 1795 it was transferred by Suwaroff to St Petersburg as a trophy of war. It then extended to 260,000 printed volumes and 10,000 MSS., but in consequence of the withdrawal of many medical and illustrated works to enrich other institutions, hardly 238,000 volumes remained in 1810. Literature, history, and theology formed the main features of the Zaluski Library; the last class alone amounted to one-fourth of the whole number. Since the commencement of this century, through the liberality of the sovereigns, the gifts of individuals, careful purchases, and the application of the law of 1810, whereby two copies of every Russian publication must be deposited here, the Imperial Library has attained its present extensive dimensions. Nearly one hundred different collections, some of them very valuable and extensive, have been added from time to time. They include, for example, the Tolstoj Slavonic collection (1830), Tischendorf's MSS. (1858), the Dolgorouky Oriental MSS. (1859), and the Firkowitsch Hebrew (Karaites) collection (1862-63), the libraries of Adelung (1858) and Tobler (1877), that of the Slavonic scholar Jungmann (1856), and the national MSS. of Karamzin (1867). This system of acquiring books, while it has made some departments exceedingly rich, has left others comparatively meagre. The library was not regularly opened to the public until 1814; it is under the control of the minister of public instruction. In the printed book department the yearly average of readers is now 107,000, and of books consulted 285,300. The annual grant from the treasury is 79,174 silver roubles; an income of 3438 roubles is derived from other sources. The official estimate of the number of printed books is 1,000,000 volumes, with 19,059 maps and 75,000 prints and photographs. The yearly accessions amount to about 28,000. The Russian books number 100,000 and the Russian 30,000 volumes; the Aldines and Elzevirs form a nearly perfect collection; and the incunabula are numerous and very instructively arranged.

The manuscripts include 26,000 codices, 41,340 autographs, 4689 charters, and 576 maps. The glory of this department is the celebrated *Codex Sinaiticus* of the Greek Bible, brought from the convent of St Catherine on Mount Sinai by Tischendorf in 1859. Other important Biblical and patristic codices are to be found among the Greek and Latin MSS.; the Hebrew MSS. include some of the most ancient that exist, and the Samaritan collection is one of the largest in Europe; the Oriental MSS. comprehend many valuable texts, and among the French are some of great historical value.

The general catalogues are in writing, but the following special catalogues of the printed books have been published—the Tolstoj collection of early printed Russian books, 1829; the Aldines, 1854; the Elzevirs, 1862, and another in 1864, by C. F. Walther; editions printed during the reign of Peter the Great, by Bytschkoff, 1867; the foreign books relating to Peter the Great by P. Minzloff, 1872; and the Russian, 2 vols., 1873. Lists of the foreign books have been issued since 1863, and the *Comptes Rendus* published since 1850 contain notices of the most important acquisitions.

The following catalogues of the MSS. are in print:—the Tolstoj Slavonic collection, 1825; Dorn's catalogue of the Oriental MSS., 1852; old German, 1853; the Greek, 1854; the Khani-koff Oriental codices, by Dorn, 1865; Russian MSS. on the history of Peter the Great, by Bytschkoff, 1872; the French, 1874; Samaritan, 1875; Hebrew Biblical, 1875; Slavonic and Russian miscellaneous, parts 1 and 2, 1878-80.

The nucleus of the library at the Hermitage Palace was formed by the empress Catherine II., who purchased the books and MSS. of Voltaire and Diderot. In the year 1861 the collection amounted to 150,000 volumes, of which nearly all not relating to the history of art were then transferred to the Imperial Library.

The second largest library in Russia is contained in the public museum at Moscow. The class of history is particularly rich, and

Russian early printed books are well represented. The MSS. number 5000, including many ancient Slavonic codices and historical documents of value. One room is devoted to a collection of Masonic MSS., which comprehend the archives of the lodges in Russia between 1816 and 1821. There is a general alphabetical catalogue in writing; the catalogue of the MSS. has been printed, as well as those of some of the special collections.

For other Russian libraries see the tables.

India, China, and Japan.

Of Indian libraries it is difficult to notice those that have Indian importance for Oriental letters. At Calcutta the Sanskrit college has 1652 printed Sanskrit volumes and 2769 Sanskrit MSS., some as old as the 14th century; there is also a large collection of Jain MSS. A catalogue is now being prepared for publication.—The Arabic library attached to the Arabic department of the Madrasa was founded about 1781, and now includes 731 printed volumes, 143 original MSS. and 151 copies, the English library of the Anglo-Persian department dates from 1854, and extends to 3254 volumes. The library of the Asiatic Society of Bengal was founded in 1784, and now contains 15,000 printed volumes, chiefly on Eastern and philological subjects, with a valuable collection of 9500 Arabic and Persian MSS. A catalogue is now passing through the press.

At Bombay the library of the Bombay branch of the Royal Asiatic Society, established in 1804 as the Literary Society of Bengal, is now an excellent general and Oriental collection of 40,000 printed volumes and 200 MSS., described in a printed catalogue of 1875. The Moolla Feroze Library was bequeathed for public use by Moolla Feroze, head priest of the Parsis of the Kundra sect in 1831, and consisted chiefly of MSS. in Arabic and Persian on history, philosophy, and astronomy; some additions of English and Gujarati works have been made, as well as of European books on Zoroastrianism. A catalogue has been printed.

The library of Tippoo Sahib, consisting of 2000 MSS., fell into the hands of the British, and a descriptive catalogue of them by Charles Stewart was published at Cambridge in 1809, 4to. A few were presented to public libraries in England, but the majority were placed in the college of Fort William, then recently established. The first volume, containing Persian and Hindustani poetry, of the *Catalogue of the Libraries of the King of Oudh*, by A. Sprenger, was published at Calcutta in 1854. The compiler shortly afterwards left the Indian service, and no measures were taken to complete the work. On the annexation of the kingdom in 1856 the ex-king is believed to have taken some of the most valuable MSS. to Calcutta, but the largest portion were left behind at Lucknow. During the siege the books were used to block up windows, &c., and those which were not destroyed were abandoned, and plundered by the soldiers. Many were burnt for fuel; a few, however, were rescued and sold by auction, and of these some were purchased for the Asiatic Society of Bengal.

Perhaps the most remarkable library in India is that of the raja of Tanjore, which dates from the end of the 16th or beginning of the 17th century, when Tanjore was under the rule of the Telugu Naiks, who collected Sanskrit MSS. written in the Telugu character. In the 18th century the Marhattas conquered the country, and since that date the library increased but slowly. By far the greater portion of the store was acquired by Sheralohji Raja during a visit to Benares in 1820-30; his successor Sivaji added a few, but of inferior value. There are now about 18,000 MSS. written in Devanagari, Nandinigari, Telugu, Kannada, Grantha, Malayalam, Bengali, Panjabi or Kashmiri, and Uriya; 8000 are on palm leaves. Dr Burnell's printed catalogue describes 12,375 articles.

Thanks to the enlightened policy of the Government of India, we are beginning to know much more respecting native libraries than was possible a few years ago, and since 1868 a yearly sum of 24,000 rupees has been granted to carry on the work of searching for Sanskrit MSS. The first part of a list of those in private hands in southern India has been published by Dr G. Oppert; it contains a description of 8376 MSS., and another volume is in course of preparation. Dr Bahler, in his investigation of Santunath's library at Cambay, found 300 MSS. of great antiquity, six dating from the beginning of the 12th century. A pundit has examined the Saughavina Pada library in Pathan, and a catalogue has been prepared for printing. A copy of the oldest Sanskrit dictionary, the *Sanskrit Kosha*, of which only one other copy (at the Bodleian) is known, was found here. Dr Bahler also purchased 429 volumes for the Government. Inquiries made in Behar have not met with much result. Notices of Sanskrit MSS. in the presidency of Bengal have been prepared under the direction of Dr Rajendralala Mitra; seven fasciculi (1000 pp.) have been printed, describing 842 articles. The same scholar has also printed a catalogue (755 pp.) of the library of the maharaja of Bikanir, describing 2000 Sanskrit MSS.; and his analysis of the Sanskrit Buddhist literature of Nepal will shortly be published. The total number of Sanskrit MSS. acquired in this presidency is now 1612, some of which are new to Europeans. Two catalogues of 180 Sanskrit MSS. discovered in the North-Western Provinces and Oudh during 1878-80 have been prepared.

and the following libraries (containing many important texts) of the Punjab have been examined:—that of Pandit Rikhikesha, of 600 books; Pandit Jwala Datta Prasada, 2500 MSS., the largest collection in the province; and Pandit Dilaram, 430 MSS. The efforts of Dr Fiechhammer will probably bring to light many valuable Sanskrit MSS., both in Upper and Lower Burma.

**Singapore.** The Raffles Library at Singapore was established as a proprietary institution in 1844, taken over by the Government in 1874, and given legal status by an ordinance passed in 1878. It now contains 11,000 volumes in general literature, but books relating to the Malayan peninsula and archipelago have been made a special feature, and since the acquisition of the collection of J. R. Logan in 1879 the library has become remarkably rich in this department.

**Batavia.** The library of the Genootschap van Kunsten en Wetenschappen at Batavia contains books printed in Netherlandish India, works relating to the Indian Archipelago and adjacent countries, and the history of the Dutch in the East. There are now 20,000 printed volumes and 1630 MSS., of which 243 are Arabic, 445 Malay, 303 Javanese, 60 Batak, and 517 on lontar leaves in the ancient Kawi, Javanese, and Bali languages, &c. The last edition of the catalogue appeared in 1877; printed catalogues of the Arabic, Malay, Javanese, and Kawi MSS. have also been issued.

**China.** *China.*—The Great Imperial Library was founded by K'in Lung, 18th century, and from a catalogue which has been issued appears to have contained about 12,000 works, extending to 168,000 volumes. There are many provincial libraries in China, and the chief Buddhist monasteries also possess collections of books.

**Japan.** *Japan.* The library of the Tokio Fu (municipality of Tokio) at Leido, in the old Chinese university, contains 65,000 Chinese and Japanese volumes, and 5000 European, principally English and Dutch. The reading-room is supplied with native daily papers, and the chief foreign periodicals. The library is open for purposes of reference, and books may be borrowed by special permission. The Asakusa Library, now occupying the former fireproof rice store-houses of the shogun, is one of the oldest in the country, and is reported to contain 143,000 volumes, including many ancient books and MSS.; an entrance fee of about 4d. is charged here. The Imperial University has a good collection of European and Japanese science and general literature. The libraries of the large temples often contain rare books of value to the philologist, and many of the leading towns throughout the country are provided with free libraries. Lending libraries of native and Chinese literature have existed in Japan from very early times.

#### *British Colonies.*

Of such libraries as may be found in the British colonies there are very few that call for particular mention here.

**Canada.** The largest collection of books in Canada is the library of parliament at Ottawa. Though founded in 1815, it contained very few books until 1841, when the two libraries of Upper and Lower Canada were joined. After being destroyed by fire, the library was re-established in 1855, chiefly for parliamentary use. It now contains 100,000 volumes, and is open to the public except when parliament is sitting. Books are lent out. The main library is a handsome octagonal apartment with beautiful carved work in Canadian white wood.

**Cape-town.** In the South African Public Library at Capetown, which was established in 1818, there are 39,000 volumes, including the collection bequeathed by Sir George Grey, comprising, besides MSS. and early printed books, an unrivalled collection of works in the native languages of Africa, Australia, &c. The library is open to any respectable person.

**Australia.** The largest library in the Australian colonies is the Public Library of Victoria at Melbourne, which was established in 1853. In 1881 it numbered 89,387 volumes with 22,257 pamphlets; it possesses a collection of works on Australasia. The library has a printed catalogue (1880). It is supported by an annual parliamentary vote, which amount, last year to £5495. Readers are admitted with any formality, and have free access to the shelves. Although books are not lent out of the library individually, there is a system by which parcels of from 100 to 400 books are lent to libraries, mechanics' institutes, &c., in the inland towns of Victoria. There are several other not inconsiderable libraries in Melbourne. Next in importance to the Melbourne Library is the Sydney Free Public Library, which is said to contain the largest collection of works on Australasia anywhere to be found. It has a lending as well as a reference department, and is much used.

Particulars of other colonial libraries will be found in the tables.

#### *United States.*

**United States.** The libraries of the United States, as we should expect to find in a country where intelligence and education are so widely diffused, are exceedingly numerous. A great mass of information with regard to them has been published by the Bureau of Education, particularly in

the comprehensive *Special Report on Public Libraries* issued in 1876. From this report, and the annual reports of the commissioners of education which have since appeared, we learn that the number of public libraries already registered is 3842, with upwards of 12,569,450 volumes. It is of course true that the great majority of these libraries are not numerically important. On the other hand, many of them are very rapidly growing, and their very youth implies that their shelves are not burdened with much obsolete literature. The recent development of American libraries is indeed very striking. Of the libraries reported in 1875, about 64 appear to have been established before 1800, and 30 of these between 1775 and 1800. Between 1800 and 1825 there were established 179 libraries, between 1825 and 1850 as many as 551, and finally between 1850 and 1875 no less than 2240, which in the latter year contained as many as 5,481,068 volumes. It will be convenient to deal with these libraries in groups according to the historical order of their development. The earliest libraries formed were in connexion with educational institutions, and the oldest is that of Harvard (1638). It was destroyed by fire in Harvard 1764, but active steps were at once taken for its restoration. From that time to the present, private donations have been the great resource of the library. In 1840 the collection was removed to Gore Hall, which was erected for the purpose with a noble bequest from Christopher Gore, formerly governor of Massachusetts. There are also nine special libraries connected with the different departments of the university. The total number of volumes in all these collections is 259,000, exclusive of over 200,000 pamphlets. The annual increase is about 7000 volumes, and the library has an endowment fund of over \$200,000. There is a MS. card-catalogue in two parts, by authors and subjects, which is accessible to the readers. The only condition of admission to use the books in Gore Hall is respectability; but only members of the university and privileged persons may borrow books. The library of Yale College, New Haven, was founded in 1700, but grew so slowly that, even with the 1000 volumes received from Bishop Berkeley in 1733, it had only increased to 4000 volumes in 1766, and some of these were lost in the revolutionary war. During the present century the collection has grown more speedily, and now the main library numbers 102,000 volumes, while the special libraries in the control of the college bring up the total to 143,000 volumes. The yearly increase is about 4500 volumes, and the library has a book fund of \$100,000. Amongst the other important university libraries are those of the college of New Jersey (Princeton), Dartmouth College (Hanover), Amherst College, Cornell University, and Brown University (Providence, R. I.). In 1875 the number of college libraries (not reckoning academy and school libraries) was 312, besides 299 libraries belonging to college students' societies.

The establishment of proprietary or subscription libraries runs back into the first half of the 18th century, and is connected with the name of Benjamin Franklin. It was at Philadelphia, in the year 1731, that he set on foot what he calls "his first project of a public nature, that for a subscription library. . . . The institution soon manifested its ability, was imitated by other towns and in other provinces." The Library Company of Philadelphia was soon regularly incorporated, and gradually drew to itself other collections of books, including the Loganian Library, which was vested in the company by the State legislature in 1792 in trust for public use. Hence the collection combines the character of a public and of a proprietary library, being freely open for reference purposes, while the books circulate only among the subscribing members. It numbers at present 123,000 volumes, of which 11,000 belong to the

Loganian Library, and may be freely lent. The printed catalogues of the library has been praised by Brunet and Allibone. In 1869 Dr James Rush left a bequest of over one million dollars for the purpose of erecting a building to be called the Ridgeway branch of the library. The building is very handsome, and has been very highly spoken of as a library structure. Philadelphia has another large proprietary library—that of the Mercantile Library Company, which was established in 1821. It possesses 143,135 volumes, and its members have always enjoyed direct access to the shelves. The library of the Boston Athenæum was established in 1807, and numbers 122,000 volumes. It has recently published an admirable dictionary-catalogue. The collection is especially rich in art and in history, and possesses a part of the library of Washington. The Mercantile Library Association of New York, which was founded in 1810, has the largest of all the subscription libraries, counting over 193,000 volumes. New York possesses two other large proprietary libraries, one of which claims to have been formed as early as 1700 as the "public" library of New York. It was organized as the New York Society Library in 1754, and has been especially the library of the old Knickerbocker families and their descendants, its contents bearing witness to its history. It contains about 80,000 volumes. The Apprentices' Library has about 63,000 volumes, and makes a special feature of works on trades and useful arts. It is maintained by the General Society of Mechanics and Tradesmen. Finally, the Brooklyn Library deserves mention, if only for its very useful and admirable catalogue, the printing of which was completed in December 1880, and which embraces 60,000 volumes.

State  
libraries. Although the State libraries of Pennsylvania and New Hampshire are known to have been established as early as 1777, it was not until some time after the revolution that any general tendency was shown to form official libraries in connexion with the State system. It is especially within the last thirty years that the number of these libraries has so increased that now every State and Territory possesses a collection of books and documents for official and public purposes. These collections depend for their increase upon annual appropriations by the several States, and upon a systematic exchange of the official publications of the general Government and of the several States and Territories. The largest is that of the State of New York at Albany, which contains 116,000 volumes, and is composed of a general and a law library, of which a printed catalogue has been published with full subject-indexes. The State libraries are libraries of reference, and only members of the official classes are allowed to borrow books, although any well-behaved person is admitted to read in the libraries.

In addition to the libraries maintained by the several States, there are the collections belonging to the general Government, most of which are at Washington. The most important of them is of course the Library of Congress, but there are also considerable libraries attached to the house of representatives, the senate, the department of state, the patent office, and the office of the surgeon-general.

Library  
of Con-  
gress. The Library of Congress was first established in 1800 at Washington, and was burned together with the Capitol by the British army in 1814. President Jefferson's books were purchased to form the foundation of a new library, which continued to increase slowly until 1851, when all but 20,000 volumes were destroyed by fire. From this time the collection has grown rapidly, and now consists of 396,000 volumes with 130,000 pamphlets. In 1866 the library of the Smithsonian Institution, consisting of 40,000 volumes, chiefly in natural science, was transferred to the library of congress. The library is specially well provided in history, jurisprudence, the political sciences, and

Americana. Since 1832 the law collections have been constituted into a special department. This is the national library. In 1870 the registry of copyrights was transferred to it under the charge of the librarian of congress. As two copies of every publication which claims copyright are required to be deposited in the library, the receipts under this head are nearly 25,000 articles per annum. The sum annually appropriated by congress for the management and increase of the library is \$52,840. The present accommodation is inadequate, and a separate building is to be erected of size to contain two million volumes. There is an alphabetical card-catalogue kept constantly up to date, and a printed catalogue of subject matters. The library is open every day in the year, except on four legal holidays, from 9 A.M. to 4 P.M., and admission is granted to all persons over sixteen years of age without formality of introduction, but books are only lent to members of the official classes.

Since the organization of the Government in 1789, more than one hundred and sixty historical societies have been organized in the United States, most of which still continue to exist. Many of them have formed considerable libraries, and some have extensive and valuable manuscript collections. The oldest of them is the Massachusetts Historical Society, which was organized in 1791.

The earliest of the scientific societies owes its origin to Franklin, and dates from 1743. The most extensive collection is that of the Academy of Natural Sciences of Philadelphia, which consists of 35,000 volumes and 40,000 pamphlets. For information as to the numerous professional libraries of the United States— theological, legal, and medical—the reader may be referred to the report already mentioned.

Of all the libraries of the United States none has achieved a greater fame, and none are more zealously and admirably maintained than those which are supported from the public funds of the great cities. Legislation on the subject of free public libraries was almost synchronous in England and America. The town libraries of America, much the largest and most important, are the Boston Public Library, which was established in 1822, and the New York Public Library, which was established in 1847. The liberal appropriations made by the city for its libraries have been the object of a long series of splendid gifts from its citizens. Among the more conspicuous of its benefactors have been John D. Bates, Theodore Parker, and George Ticknor. Since the library has been opened to the public there has thus been a great increase in the collection of books, and in the number of persons who use the library. The number of volumes in the library in 1881, was 395,478, and the annual accessions were 17,000. In addition to the income available from the city, the annual appropriation by the city is \$115,000. The library is a central library, with the Bates Hall and Lower Hall, and has eight branches, and the total circulation is considerably over 1,000,000 volumes per annum. Any inhabitant of Boston over sixteen years of age is admitted to read in the library, and to borrow books. The principal catalogue of the library is up to date, and in addition to which there are printed catalogues of special collections, and a perfect multitude of useful class catalogues and bibliographical helps of various kinds. The number of persons engaged in the service of the library is one hundred and forty-three. The library is open to readers from 9 A.M. to 6 P.M. from October to March, and until 7 P.M. during the rest of the year. Books are delivered for home use until 9 in the evening. The periodical room is open from 2 A.M. to 9 P.M. on week days, and on Sundays from 2 to 9. A new building is in contemplation.

Of the remaining free town libraries, the most important are those of Cincinnati and Chicago. The Chicago Public Library, which was established on its present site in 1872, and now contains 22,920 volumes besides pamphlets. Its expenditure for the year was \$51,465, and its total issues, including those of its branches, were 768,565. The reading-rooms are open every day in the year from 8 A.M. to 10 P.M. The library buildings were completed in 1873 at a cost of about \$100,000, and are "one of the handsomest in the world." The Chicago Public Library was established in 1872, and owed its origin to the sympathy felt for Chicago in England after the great fire of 1871. The number of volumes now in the library is 76,120. There is a very full and minute card-catalogue, in one alphabet, of authors and subjects; the contents of collections, volumes of essays, &c., are analysed under their subjects. The reading room is open three hundred and sixty-five days in the year from 9 A.M. to 9 P.M., and is not even closed for the purpose of taking stock or cleaning. The library has not yet an adequate building. Of smaller free town libraries there is a considerable number, especially in Massachusetts. Of the entire number ten only possess over 30,000 volumes each. It is the opinion of the energetic and

enlightened managers of these libraries that a free public library is the proper corollary of a free system of public education, and it is their aim as far as possible to direct the taste and to methodize the reading of those who use the collections under their charge.

**Astor library.** We cannot conclude this brief sketch without mentioning some notable illustrations of that public-spirited munificence which is nowhere perhaps so frequently found as in the United States. The Astor Library in New York was founded by a bequest of John Jacob Astor, whose example was followed successively by his son and grandson. The library was opened to the public in 1854, and at the end of 1880 the collection due to their joint benefaction contained 192,547 volumes. It consists of a careful selection of the most valuable books upon all subjects. It is a library of reference, for which purpose it is freely open, and books are not lent out. It is "a working library for studious persons," and such persons on a proper introduction are allowed to pursue their studies in the alcoves. In 1880 the number of general readers was 45,670, and the number of visits to the alcoves was 7961. The total endowment is over \$1,100,000. There is a printed catalogue for about half the library, with a printed index of subjects, and a similar catalogue for the rest is in preparation. The Lenox Library was established by Mr. James Lenox in 1870, when a body of trustees was incorporated by an Act of the legislature. In addition to the funds intended for the library building and endowment, amounting to \$1,247,000, the private collection of books which Mr. Lenox has long been accumulating is extremely valuable. Though it does not rank high in point of mere numbers, it is exceedingly rich in early books on America, in Bibles, in Shakespeariana, and in Elizabethan poetry. The Peabody Institute at Baltimore was established by Mr. George Peabody in 1857, and contains a reference library open to all comers, numbering about 72,000 volumes. The institute has an endowment of \$1,000,000, which, however, has to support, besides the library, a conservatoire of music, an art gallery, and courses of popular lectures. The largest legacy yet made for a public library has recently fallen to the citizens of Chicago in the Newberry bequest of over \$2,000,000 for the founding of a free public library in the north division of Chicago.

#### South America and Mexico.

**Argentine Republic.** The importance of public libraries has been fully recognized by the Argentines, and at present more than two hundred of them are in the country. They are due to benefactions, but the Government in every case adds an equal sum to any endowment. A central commission exists for the purpose of facilitating the acquisition of books and to promote a uniform excellence of administration. The most considerable is the Biblioteca Nacional at Buenos-Ayres, which contains at present 40,000 volumes, and has been almost doubled since 1872. It is especially rich in MSS., some of great interest, concerning the early history of the Spanish colonies.

**Brazil.** The chief library of Brazil is the Bibliotheca Publica Nacional at Rio de Janeiro, founded in 1807, and now comprising 120,000 printed volumes with 1000 MSS. National literature and works connected with South America are special features of this collection. The Royal Library of Ajuda (in 1800 MSS.) was taken to Brazil by King João VI., but was sent to Portugal on the declaration of independence. Since 1873 the annual Government grant has been largely increased. Among other libraries of the capital may be mentioned those of the Faculty of Medicine (18,000 volumes), Marine Library (19,500 volumes), National Museum (9000 volumes), Portuguese Literary Club (53,000 volumes), Bibliotheca Fluminense (43,000 volumes), Benedictine Monastery (9000 volumes), and the Bibliotheca Municipal (15,500 volumes). In the official report on Brazil, submitted at the Philadelphia Exhibition in 1876, it was stated that the aggregate number of volumes in all the libraries of the empire accessible to the public was then 460,272 volumes. In 1875 the libraries were visited by 85,044 persons.

**Chili.** The Biblioteca Nacional at Santiago is the chief library in Chili. The catalogue is printed, and is kept up by annual supplements.

**Mexico.** Only sixteen out of the twenty-nine states and territories of the Mexican republic have public libraries, and only a small proportion of the contents consists of modern literature. Many, however, possess rare and valuable books, of interest to the bibliographer and historian, which have come from the libraries of the suppressed religious bodies. It is calculated that books in all the public libraries amount to about 250,000 volumes. There are about seventy-three scientific and literary associations in the republic, each possessing books. The Society of Geography and Statistics, founded in 1851, is the most important of them, and owns a fine museum and excellent library. After the triumph of the Liberal party the cathedral, university, and conventual libraries of the city of Mexico came into the possession of the national government, and steps were taken to form them into one national collection. No definite system was organized, however, until 1867, when the church of San Augustin was taken and fitted up for the purpose. Two copies of every book printed in Mexico must be presented to this library. The only other public library in the city is the Biblioteca Cinco de Mayo, which is under the management of the Lancastrian Society.

The Biblioteca Nacional at Lima was founded by a decree of the liberator San Martin on August 28, 1821, and placed in the house of the old convent of San Pedro. The nucleus of the library consisted of those of the university of San Marcos and of several monasteries, and a large present of books was also made by San Martin. The library is chiefly interesting from containing so many MSS. and rare books relating to the history of Peru in vice-regal times. The volumes marked "Papeles varios" contain reports on the superstitions of the Indians, abstracts of the ecclesiastical councils of Lima, and memoirs on provincial administration and petitions. It is reported (1881) that the whole library has been seized by the Chilians and transferred to Santiago.

#### LIBRARY MANAGEMENT.

*Library Buildings.*<sup>1</sup>—The conditions of no two libraries being precisely alike, it is impossible to lay down rules to suit all, but certain principles of general application may be stated. In the first place the internal arrangements ought to be devised by a person thoroughly acquainted with the practical working of such a library as the building is intended to accommodate. The reading-rooms, book-rooms, work-rooms, and offices should be made to fall into the most convenient relations one to the other. And as libraries grow with wonderful rapidity the plan ought to admit of easy development. The site should be dry and airy, and permit isolation of the fabric, which should be constructed of fire-proof materials, iron being preferable to stone, and brick to either. Every floor should be laid upon rolled iron beams, supported by lattice girders, the space between the beams being fitted in with porous terra cotta, and the beams covered with concrete. To protect them against fire, girders and pillars must be covered with terra cotta. Iron doors (or, better still, stout wooden doors plated with thin iron) should separate the different rooms.<sup>2</sup> The safety and convenient disposal of the books must never be sacrificed to outside show. The old form of library, the museum-like room with alcoves and a large block of vacant space in the centre, or the series of apartments with books on the walls only, is no longer in favour. The reading-room, commodious, well lighted, and supplied with works of reference, should be away from the main collection, and the lending department should be kept apart from the reference library. It is convenient to have separate rooms for ladies and for readers to whom special facilities may be granted; and let ample provision be made for work-rooms, librarians' offices, cataloguing rooms, and a bindery if necessary. The chief portion of the books (at any rate those in most demand) should be on the ground floor, and more than two stories are to be avoided. Plenty of light and good ventilation are two conditions of great importance. The basement should be vaulted. As the store-room, or that in which the main collection is deposited, is one to which readers have seldom the right of access, the greatest economy as to shelving and passage way may be effected. Bookcases may be placed against the walls, but not too close to them, and double presses, about 3 feet apart, arranged across the floor. To prevent the objectionable use of high ladders, no shelf should stand more than 8 feet above the ground. If the room be sufficiently lofty it may contain one or more perforated iron floors, sustained by the upright portion of the presses, also of iron. Spiral staircases are to be avoided. Lifts may be introduced with advantage. In many college libraries in America (e.g. at Princeton) the circular form, with cases radiating from the centre, has been adopted successfully. The spacious rotundas of the British Museum and that of the Liverpool Free Public Library are good examples of the circular reading-room.

Mr. Justin Winsor has devised an excellent plan for a library of one million volumes capacity (see "Library Buildings," in *Report on Public Libraries of U.S.*, p. 465), and the same system might be applied to one much less extensive. Another distinguished American librarian, Mr. W. F. Poole of Chicago, has made some novel suggestions on library architecture which have met with considerable approval. He objects to the waste of space in the central portion of most large library rooms, to the difficulty of ventilating and heating them, to shelving books in galleries on the walls, to the destruction of bindings from gas and heat ("books cannot live where man cannot live"), to the excessive labour of procuring books from long distances, the insecurity from fire, the inconvenience of keeping many volumes (other than those of reference) in the public reading-room, and the unnecessary cost of the present system. To remedy these defects a plot of land is required 200 feet square, and surrounded with open spaces. At the middle of the principal side may be placed the main building, 60 feet front and 75 feet deep, devoted to administrative and working purposes. The books will be stored, not in one central repository, but in a series of rooms thrown out in wings from the central edifice, and

<sup>1</sup> Plans of most of the chief libraries of Europe may be seen in the *Memoirs of Libraries of Mr. Edwards* (2 vols., 1859), and in the *Katechismus der Bibliothekswissenschaft* of Dr. Petzholdt (1871); the volumes of the *Library Journal* contain representations of many new American libraries.

<sup>2</sup> A recipe to make wood incombustible, and other suggestions, are given by C. Walford in *Manchester Trans. Libr. Assoc.*, 1880, p. 63.

...round the four sides of the quadrangle with a vacant space in the middle. Each room is 50 feet wide, 15 feet high, and as long as convenient. Ten of these rooms will occupy the ground floor, so that, carrying the same construction four stories high, there will be forty different rooms in the whole structure. Each will be devoted to one large, or two or more small, classes of books. Alcoves and galleries are not to be permitted, but the books will be shelved on the walls or on double presses within reach. Every room will receive light on two sides, will be furnished with tables and chairs for readers, and provided with an attendant; no general reading-room will therefore be wanted. As a protection against fire, each room will be cut off by means of brick fire-walls extending to the roof, and access from one room to the other will be by a light iron corridor on the inside of the quadrangle. At the rear of the central building will be a lift for readers, and there will be staircases as well. In this way, on one story there will be about 25,250 square feet in the different wings, which, after deducting sufficient space for readers' tables, &c., will give about 20,200 square feet for books. At each square foot will shelf 25 volumes, each story will hold 505,000 volumes, or on the four stories 2,020,000 volumes. One of the front rooms (to hold 67,500 volumes) might serve as a circulating library. Mr Poole estimates the cost of such a building in America at \$380,000, or complete with shelving and furniture \$440,000. (See *Library Journal*, vi. 69 &c.) If the same volume, p. 77 &c., is a description of the proposed plan for a new national library building at Washington. In this scheme the architect has in view the centralization towards a circular reading-room, good light, the possible expansion of the library for one hundred years, accessibility to all parts, economical administration, and division into different fire-proof compartments.

**Heating.** Of the various systems for heating libraries open fire-places have the best appearance, are very safe, and best economy heat; close stoves are the cheapest at first hand. Perhaps steam heating is the safest and most economical for large buildings. Unprotected gas jets are very injurious to the books. If gas be used at all, the sun-light system or the Benham light is the best means of conveying away the fumes and heated air. The electric light is used with great success at Liverpool and in the British Museum.

**Shelves.** *Bookcases and Shelves, Furniture and Appliances.*<sup>1</sup> For presses and shelves, should wood be preferred, English oak or the cheaper deal (well seasoned) is the best material; or the presses may be made of iron and the shelves of slate or galvanized iron. At the British Museum the presses are all on one scale and all of the same model, the standards being of galvanized iron, with holes for brass pins, which are so shaped that the space is altered by merely turning them half-way round. The shelves are also of galvanized iron, covered with leather, on wooden frames; movable pads covered with leather protect the books at either end from being rubbed, and there are leather falls to keep the dust out. In the Radcliffe iron bookcase, invented by Dr Arundel, the framework is of iron, and the shelves of wood, faced with leather. It is 7 feet high, and stands on any floor-space 18 inches by 18 inches; books are placed on both sides to the number of 500 octaves. Danner's revolving bookcase is useful for reference books; it is square, stands about 5 feet high, occupies no more space than a chair, and holds about 250 volumes. Economy of space is also a feature in Mr Vign's bookcase, in the front of which is a door, itself shelved, which, on being swung round, discloses another row of shelves behind. The small portable bookcase can be taken to pieces, and is made to stand against a wall. In providing for shelf room it is usual to allow about 110 square feet of shelving to 1000 volumes; and in giving directions for presses and shelves it is well to have them planned upon a uniform scale. Perhaps the best supports for the shelves are Radcliffe's movable shelf-fittings, consisting of two rows of metal strips, with oblong perforations at intervals of  $\frac{1}{2}$  inch, in which are inserted small metal plates. The tops of reading tables, trays and drawers for carrying books, and such shelves as may be intended for heavy or choice books, should be padded. Very large volumes and letter-presses should be flat in sliding trays. There is much diversity of opinion as to whether the fronts of the presses should be glazed or not, or whether they should be protected by wooden doors, curtains, or wire screens; in dry air, and to an

**Reading-room.** The arrangement of the reading-room of the British Museum is of perfect supervision combined with comfort of readers. The tables are of a wheel, with smaller square tables of 4 feet 3 inches long, and is screened from a division running along from one end to the other, with racks, inkstand, and a network of each table is of iron, forming channels by which air is conveyed through screens at the top of the longitudinal divisions. A tubular foot-rail affords facility for warming the feet in cold weather. The catalogue-stands (with

presses of special bibliographies near them) are placed in two concentric circles around the enclosure of the superintendent, who can thus observe every reader in the room.

A speedy supply of books is ensured by the use of the automatic Supply, book-delivery contrived for the Harvard bookstore (of six stories) by Mr Justin Winsor. At the delivery-desk a keyboard shows the digits which combine the various shelf-marks; and the number of the book wanted, being struck upon it, is repeated at the floor on which the work is located, where it is sought for by an attendant and placed in a box attached to an endless belt, which carefully deposits it on a cushioned receptacle close by the delivery-desk.

Many English lending libraries find that a great saving of time and trouble both to officials and readers is made by the use of the cators, indicator for public reference. There are many varieties of this invention, but the main principle is a frame containing a series of small pigeon-holes, each numbered and referring by that number to a book; when a volume is lent out, the borrower's card, &c., are placed in the pigeon hole and sent to it as it is absent. This roughly describes the Birmingham indicator. Mr Morgan's; in that of Mr Elliot, the title of the book is pasted against each pigeon-hole; Mr W. H. K. Wright uses at Plymouth a system which serves as a catalogue and register of books lent as well; and Mr A. Cotgrave has improved the original idea by his indicator-book, a sort of ledger of the persons to whom each volume is lent, which is placed in the small pigeon-hole previous to its being lent. The end-ledger of Mr G. Parr, used at the London Library, is for the use of the librarians alone and not for the reader. It is applied to a borrowing system which permits several volumes to be taken away by the same person, and also acts as a register of borrowers.

For the purpose of stamping the name of the library on the books, &c., some persons prefer the embossing stamp, and some the ink stamp now very conveniently made in molten lead. Properly, either to screw upon the shelves, or made of thick black wood, or of tin folded at right angles, are useful for protecting the books, lying about in a slovenly manner. Reading-rooms are not only for periodicals and choice bindings, periodicals are not only for periodicals of wood with strong leather backs. In order to keep numbers of current periodicals and newspapers in perfect order, some kind of temporary binder is required. The contents of the different shelves or trays are to be placed in small bags of leather or cloth. The "Van Eyck" problem is and letters for the marks on the shelves, and the books to be purchased at a small cost.

*Classification and Shelf-Arrangement.*—The defect of a too systematic systems, especially of those which profess to be scientific, is that they are not logical, is that they are not adapted to a systematic review of human knowledge than for the arrangement of a miscellaneous collection of books. A small library will not require so extensive a scheme as a larger one, and a popular library needs less minute classification than one for reference or for those of more learned readers. Again, the classes which are best represented in the library, and its special local collections, should receive elaborate treatment than the classes in which it possesses but few volumes. The same system cannot invariably be used in all respects, both for the shelves and for the catalogue, as a book can be better placed in the presses, but the title may appear in many different headings in different parts of the catalogue. For these reasons, the natural order should be followed as far as possible. That is to say, the books should suggest their own classification, which should be made to harmonize with the requirements of the library, and the various classes should not be strained to fit some artificial, or however logical in theory. As the title of a book is often an unsafe guide to its contents, no one should expect classification by the help of the title alone. In vol. ii. of Mr Peacock's *Memories of Libraries*, he gives a number of schemes for the classification and on natural or practical principles; and Mr Peacock, in his *Bibliotheca Bibliographica* (Leipzig, 1866), has given an account of no less than one hundred and seventeen different methods of classification, a number which could now be largely increased, as the practical ingenuity of American librarians alone has added many to the roll. Some of these schemes have been elaborated with great care, but, however interesting on account of the useful hints they may now and then supply, most of them are useless either for the catalogue or the shelves. All these systems to classify the whole range of literature, but there are many established bibliographies and other guides useful for the scientific arrangement of special departments.

Books are usually arranged upon the shelves either in order of (1) their sizes, (2) authors' names, (3) subjects, or sometimes (4) of accession, or by a modification of two or more of these systems. The arrangement by subjects is that which displays

<sup>1</sup> See *Oxford Trans. Lib. Assoc.*, 1870, p. 76; *Memories of Libraries*, 1870, pp. 71 &c.

<sup>2</sup> For instance, in the class of fine arts may be consulted the *Bibliotheca Reaux-Arts* (Paris, 1871-9), which the late M. Ernest Viet not inconveniently; botany may be classified with the help of Mr B. D. Jackson's *Book to the Literature of Botany* (London, 1881). In the *Memories of Libraries* (p. 212) Mr Peacock found a useful classification for MSS., and further on an account of perhaps the best systems for prints and maps, being those of the Bibliotheca on National

most conveniently the richness or poverty of the collection. Although a library may possess the most complete of subject catalogues, it cannot be considered in perfect order without classification on the shelves. In carrying out shelf-arrangement ample space should be left for additions, and in fixing upon the places of the bookcases those containing the works in most demand should be nearest the point of delivery. In some libraries the books are located without any classification, and the shelf marks are all in all. At Munich and many other Continental libraries there are thirty or forty classes, designated by single or double letters, and the books are arranged in sets of octavo, quarto, and folio in the different classes under the names of their authors, so that Macaulay's *History of England* would be found in the octavo alphabet under M of the class "history." Mr Richard Garnett supplies an interesting description of the system of classifying books on the shelves followed at the British Museum in the *Treatise of Conf. of Libs.* (London, 1878, pp. 108, 188). "There are ten classes:—(1) theology, (2) jurisprudence, (3) natural history and medicine, (4) archaeology and arts, (5) philosophy, (6) history, (7) geography, (8) biography, (9) belles lettres, (10) philology; and the classes have five hundred and fifteen divisions. Periodicals, accidental publications, state papers, the Oriental departments, the Grenville Library, and the reference library are all distinct, but the principle of classification is practically identical. By allowing intervals in the numbering of the presses space is allowed for new ones to contain additions, and as the different presses are alike in size, they may be shifted at will and no alteration of press-marks is wanted. Mr Edwards (*Man. of Libs.*, ii. 814) proposes a system for a public free library of upwards of thirty thousand volumes to be arranged under (1) theology, (2) philosophy, (3) history, (4) politics and commerce, (5) sciences and arts, (6) literature and polygraphy. A model scheme, marked with many practical advantages, is the Amherst or Dewey system,<sup>1</sup> according to which the library is divided into ten classes, the first being a zero or general class, including bibliography, polygraphy, general periodicals, &c., while the others are philosophy, which is numbered 100; theology, 200; zoology, 300; philology, 400; natural science, 500; useful arts, 600; fine arts, 700; literature, 800; and history, 900. These classes are then separated again into nine special divisions of the main subject, preceded by a zero or general division. Each of these divisions again has nine sections (preceded by a zero). Thus 511 is the third section geometry of the first division, mathematics of the fifth class, natural science. This is the classification or class number, and is affixed to every book and pamphlet belonging to the library. The zero in a class number has its normal power, and signifies a general title, so that 500 is a book on natural science in general. The system was devised in the first instance for classifying and indexing, but it can also be used for numbering and arranging books and pamphlets on the shelves. For this purpose the absolute location by shelf and book-number is wholly abandoned, and the relative location by class and book-number is used instead. Accompanying the class-number is the book-number, which prevents confusion of different books on the same subject. Thus the first geometry catalogued is marked 513.1, the second 513.2, and so on. The books of each section are all together, arranged by book numbers, and these sections are also arranged in simple numerical order throughout the library. The number 513.11 will therefore mean the eleventh book in subject 513, or the eleventh geometry belonging to the library. A representative specimen of the philosophical method is that devised by Dr W. J. Harris for the catalogue of the Public School Library of St. Louis, which is classed in a modified form of the Baconian plan. The main classes are (1) science, including philosophy, theology, social and political sciences, and natural science and the useful arts, (2) art, (3) history, (4) appendix, including polygraphy, encyclopedias, and periodicals. These main classes are again divided into one hundred subclasses, many of which are divided still further. Thus, under natural history, class 50 is zoology; 50a, vertebrates; 50a i, mammals, &c. The divisions *Medicine and Research France* in the great printed catalogue of the Bibliothèque Nationale are excellent examples of classification.<sup>2</sup>

Every volume upon the shelves should have a mark to indicate its position. One system is to designate each press by a number, each shelf by a letter, and if necessary, each volume on the shelf by another consecutive number, so that F D 16 is the sixteenth volume on the fourth shelf of the thirteenth press. The principles underlying numbering systems as well as shelf-arrangement are discussed by Mr Melvil Dewey (*Library Journal*, iv. 7, 75, 117, 191), and the combined system of numbering and arranging of Mr J. Schwartz, as well as his mnemonic system of classification (*ib.*, iii. 6; iv. 3), are also well worth attention. The new scheme of classification devised for the use of the Boston Athenæum by

Mr Cutter is also described in the *Library Journal*, iv. 234. A catalogue of the Winchester Library (1879) was prepared by Mr Cutter on the principles there detailed.

Many authorities strongly recommend that, instead of a fixed mark for the shelves, the location of books should be indicated by a running number or combination of letters and numbers; so that, although the books should not always remain in the same place, their relative position would be unaltered, and, while they could be found just as readily by means of the number, any quantity or additions could be introduced without affecting the whole scheme.

In a circulating library it may be found convenient to designate each press by letter, and to omit to number the shelves from top to bottom, but number each volume consecutively. The shelf-notation may be placed inside each volume or on a label upon the back.

**Binding.** The best binding is the cheapest in the end, since it lasts longer under all circumstances, and is always better treated by readers. Morocco resists wear and tear and the action of gas and heated air better than any other leather. Vellum is the most durable material, but it is not suitable for all purposes. Then follow in order of merit calf, russin, basil, roan, buckram, and cloth. Morocco should be used as much and russin as little as possible. Buckram, mohair, cretonne, leatherette, &c., have met with favour from time to time, but are not recommended. Olive, light brown, and red are said to be the most lasting colours; then come dark blue and green, light blue and green. Black is a lasting colour. Some persons assign a particular colour to each class of literature, but as there are more classes than colours to suit them, such an arrangement consistently carried out can only lead to confusion; besides, a want of variety on the shelves destroys at once the individual appearance which it is always desirable to give to each set of books in order to make them easily distinguishable. The Council of the Library Association have suggested a pattern for ordinary library binding that the volumes should be sewn all along, with the first and last sheets overcast, on strong cords, the slips to be drawn in all along, and the backs flexible; half-bound, with corners of same material; cloth sides; edges cut, sprinkled, and burnished, or, if so directed, top edge only cut, &c., the others trimmed and left with out; end-papers of stout Colby's paper, with cloth joints in quarters and folios; lettered with author's name, short title, and date; gilt titles, but no other tooling; two-page plates to be guarded so as to open out flat; all materials of the best quality, and the work to be done carefully.<sup>3</sup>

In making contracts some such specification as that suggested by the Library Association should be decided upon. Full instructions should always accompany work sent out, and a copy must be kept in a binding-register. Rare and valuable books demand constant attention and a special binder. The British Museum authorities have adopted a style of binding in half-morocco, with the leather coming only just over the back to act as a hinge, the sides whole cloth, the corners tipped with vellum.

How to deal with pamphlets is a troublesome question. At the Panple British Museum each was formerly done up separately in slightlets, binding. This is certainly the best system, but out of the reach of most libraries. Failing this, the pamphlets can be arranged in volumes as they come in, and afterwards bound up in volumes ordered by size and subject, with the contents marked on the fly-leaf each. The rebinding of a MS. is to be avoided; it is better to preserve the old cover and place the book

Drawings and prints are best preserved in sunk mounts,

Maps, charts, &c., should be backed with thin linen.

**Practical Hints.** Collate every volume when it comes in, so as to prevent binder's imperfections; remove plate-paper when the book is quite dry; straws and silk registers are to be avoided, as they tear the leaves; preserve old bindings as far as possible, and do not permit book-plates, the names of former owners, and MS. corners of any kind to be destroyed; be careful with metal clasps and notes; let gilding be used sparingly; do not hurry the binder overmuch, as he may retaliate by returning his work insufficiently dried and pressed; be careful with letterings; index dictionaries and works of reference on the fore edges; bind up paper wrappers; never let a binder exercise his fatal proclivity to cut away full margins.

For the removal of grease and ink-spots, and the restoration of old bindings, print, &c., consult *L'art de restaurer les estampes et les livres* (Paris, 1858) and *La réparation des vieilles reliures* (*ib.*, 1855), both by A. Bonnardot, and *Rouveyre, Connaissance nécessaire d'un Bibliophile* (Paris, 1880). To restore calf-bindings which have become impoverished, it has been recommended<sup>4</sup> that they should be lightly washed with a soft sponge dipped in a preparation consisting of 4 oz. of the best glue, dissolved in a pint of warm water, to which add a teaspoonful of glycerin and a little flour paste. Should the state of the leather be very bad, a second

<sup>1</sup> See *A Classification and Subject Index for Cataloguing and Arranging the Books and Pamphlets of a Library*, by Melvil Dewey, Amherst (Mass.), 1876.

<sup>2</sup> A proposal for a new consecutive catalogue and subject-index is made by Mr. Wilson in his contribution, "Classification in Public Libraries," to the *Transactions, &c., of Library Association at Manchester* (London, 1880, pp. 79, and in the same work (p. 85) may be read some remarks on the various notations used in reporting statistics of issues in the chief public free libraries.

<sup>3</sup> For an account of the history and practice of binding consult the article *BOOKBINDING* (vol. iv. p. 41 *sq.*); also Marthe-Michel, *La Reliure Française artistique* (Paris, 1880), and *La Reliure Française depuis l'invention de l'imprimerie jusqu'à nos jours* (Paris, 1881); *La Reliure, ancienne et moderne*, Paris, 1878; J. W. Zacharodoff, *The Art of Bookbinding*, London, 1880.

<sup>4</sup> *Monthly Notes of Lib. Assoc.*, vol. II. p. 32.

<sup>5</sup> By Mr C. P. Russell, *Oxford Meeting of Library Association*, p. 100

dressing may be found necessary. The volumes must be rubbed with chamois leather when dry. Neat's-foot or olive oil has been suggested for the same purpose, but it ought to be used with a sparing hand. Much has been written about the effect of gas and heat upon binding.<sup>1</sup> The question is still undecided, but it seems likely that the deterioration of the leather is caused more directly by the over-heated air, so that thorough ventilation, especially as regards the upper shelves, is most important for the well-being of a library. Morocco, vellum, and buckram resist this action best, and calf, russia, and roan worst. Professor H. A. Hagen has studied the various kinds of bookworms and other insect pests of librarians.<sup>2</sup> Most libraries of the first class bind on the premises, and M. Hipp. Gariel of the Bibliothèque de Grenoble is persuaded, after a very careful inquiry, that any library which binds as many as nine hundred volumes a year will save largely by keeping up a binding establishment of its own.<sup>3</sup>

Catalogues.

**Catalogues and Cataloguing.**—A library is useless without a proper equipment of good catalogues, which to be thoroughly efficient should be compiled upon a well-considered plan, carefully kept up to date, and made accessible to every reader. The variety of different catalogues is very great, and no one form can be adopted alike by libraries for study and those for popular reading, nor yet by those which combine the two functions in whatever proportions. As regards the amount of information necessary to be given, the titles of the books may be either short, or not more than a single line to each, as in the *London Library Catalogue* (1875); medium, or several lines to each, as in the *Royal Academy Library Catalogue* (1877); or full, as in the *Catalogue of the Hoth Library*, 5 vols. large 8vo (1880), where the titles are extensive and a quantity of bibliographical details are added.

The chief questions to be answered by a catalogue are:—1. Has the library a certain work? 2. What has it? 3. What is a certain book of which the title only is known to the inquirer? 4. Has it a certain book of which the subject only is known to the inquirer? 5. What has it on a given subject? 6. What works in certain class or languages has it? To supply this information, catalogues are arranged sometimes under the names of the authors in alphabetical order (1 and 2); or under the first words of the titles (3); or classified under subjects, whether in alphabetical or systematic order (4 and 5); or by a combination of two or more of these methods. A dictionary catalogue answers all six questions under the names of authors, the titles of books, the subjects and forms of literature (*i.e.*, essays, or French, German, &c.), which are arranged in one alphabet and connected one with the other by a complete system of cross-references. A modified form of short-title dictionary-catalogue, with the names of authors, titles of books, and subjects in one alphabet, is a useful type for a popular library to adopt. No author-catalogue can be considered complete without an index of subjects,<sup>4</sup> and every classified catalogue requires an index of authors, if alphabetical, and of both authors and classes if systematic. An ideal catalogue would furnish references under each name and subject to every work, part of work, or even magazine article contained in the library which illustrated it. This can only be attempted, but a near approach to perfection is shown by the new catalogues of the Boston Athenæum and the Brooklyn Mercantile Library; the last is a model of thoroughness. It is becoming a laudable practice to give the contents of collected works and periodicals in catalogues; and good examples of the value of annotations are the catalogues of the classes of history, biography, travel, and historical fiction in the Boston Public Library.

In making choice of a form of catalogue the way is sufficiently plain should the alphabetical system under authors be adopted, neither can there be much cause for discussion in fixing upon an alphabetical subject-catalogue; but, should it be decided to compile a systematic subject-catalogue, the question becomes a much more serious one. A subject-index of some sort is an indispensable supplement to any catalogue merely arranged under authors. The references had better be strictly alphabetical in form; for instance, a work on ants should be indexed under that word and not under the general heading of insects or entomology; but there is no reason why there should not be cross references under the larger to the smaller headings. In an appendix to Mr Cutter's article on "Library Catalogues"<sup>5</sup> there is a descriptive list of more than a thousand printed catalogues of American libraries, from which many useful types might be selected. All the printed catalogues of European libraries which were published before 1840 are mentioned in Vogel's *Literatur europ. öff. u. Corporations-Bibliotheken* (Leipzig, 1840).

Librarians should take a share in the compilation of their catalogues at any sacrifice of time and trouble, for by no other means can they obtain so exact an acquaintance with their collections. No

cataloguer should be allowed to prepare a title except from the very copy of the book which he is cataloguing.

In order to secure precision and uniformity in the descriptions of the books and in the headings under which they are placed, some well-considered code of rules is absolutely necessary as a guide to the cataloguer. All such rules are founded more or less upon those of the British Museum, printed in 1811,<sup>6</sup> which have been followed with modifications by Professor Jewett (in the *Smithsonian Report on the Construction of Catalogues*, 1852), by Mr E. Edwards (*Manual of Libs.*, 1859, vol. ii.), by Mr F. B. Perkins (in the *American Publisher*, 1869), with many additions by Mr C. A. Cutter (in his *Rules for a printed Dictionary Catalogue*, 1876,<sup>7</sup> by the condensed rules of the American Library Association (*Library Journal*, vi. 12), and by the Library Association of the United Kingdom (as finally agreed upon and printed in their *Manual of Libs.*, 1881). The authorities of the University Library have adopted their rules. In drawing up a set of rules the position of the library and the readers should be not forgotten, and the rules should be made rules chosen from one or other of the systems mentioned above. But when rules are decided upon, no alterations should be permitted during the compilation of the catalogue, and the rules should uniformly follow the same letter than each other, and not vary in form.

Among the many questions that of late have troubled the sizes of books is perhaps the most acute. When we want a system that can be used by every one, and which is not of being applied to books of all sizes, we are at a loss. The introduction of the introduction of books of all sizes into the library of the century, the most beautiful specimen of a book ever known, the folio of the 16th century, the quarto of the 17th century, the octavo of the 18th century, the folio of the 19th century, the quarto of the 20th century, the octavo of the 21st century, the folio of the 22nd century, the quarto of the 23rd century, the octavo of the 24th century, the folio of the 25th century, the quarto of the 26th century, the octavo of the 27th century, the folio of the 28th century, the quarto of the 29th century, the octavo of the 30th century, the folio of the 31st century, the quarto of the 32nd century, the octavo of the 33rd century, the folio of the 34th century, the quarto of the 35th century, the octavo of the 36th century, the folio of the 37th century, the quarto of the 38th century, the octavo of the 39th century, the folio of the 40th century, the quarto of the 41st century, the octavo of the 42nd century, the folio of the 43rd century, the quarto of the 44th century, the octavo of the 45th century, the folio of the 46th century, the quarto of the 47th century, the octavo of the 48th century, the folio of the 49th century, the quarto of the 50th century, the octavo of the 51st century, the folio of the 52nd century, the quarto of the 53rd century, the octavo of the 54th century, the folio of the 55th century, the quarto of the 56th century, the octavo of the 57th century, the folio of the 58th century, the quarto of the 59th century, the octavo of the 60th century, the folio of the 61st century, the quarto of the 62nd century, the octavo of the 63rd century, the folio of the 64th century, the quarto of the 65th century, the octavo of the 66th century, the folio of the 67th century, the quarto of the 68th century, the octavo of the 69th century, the folio of the 70th century, the quarto of the 71st century, the octavo of the 72nd century, the folio of the 73rd century, the quarto of the 74th century, the octavo of the 75th century, the folio of the 76th century, the quarto of the 77th century, the octavo of the 78th century, the folio of the 79th century, the quarto tents of every press and every shelf. These tell the source and date of every addition, and enable all the books to be checked at any time. A novel form of accessions-catalogue is that of the Liverpool Free Public Library, which is a sort of large photographic album to show printed titles of accessions in alphabetical order; loose sheets are placed into the body of the catalogue to provide for any number of additions as quickly as possible. In the same library the titles of new books are also posted upon blocks arranged in a frame for the information of readers.

Adminis-  
tration.

**Administration.**—In any library which manages its own financial matters, however small, all accounts should be as carefully kept as those of a trading establishment. In the same way a periodical stock-taking should be made by means of the shelf-catalogue. It is a great convenience to display recent accessions for a short time in some place put apart for the purpose. A recommendation and complaint-book are both useful. The rapid and efficient supply of books is greatly promoted by requiring that all demands should be made in writing and not verbally. The books should be carefully dusted from time to time by experienced persons; and the leaves of all new books, &c., should be cut by the library staff.

In issuing and taking note of books lent, either the ledger or the slip-system may be used, or a combination of the two, something like a shelf-catalogue. Accounts are kept either against the borrower, against the book, or against time; the first, with the ledger system, may be well for small libraries, but in larger institutions the slip-system must be resorted to, and it is better to keep the accounts against the books, with perhaps a ledger-index of borrowers. Where more than one volume is lent at a time a small card is sometimes placed in a pocket in each book; the card, whether marked with borrower's name, &c., or not, being retained as a voucher, as in the "card-ledger" spoken of on p. 537, which is on the slip-system with the account against the borrower. The special feature of the "card-ledger" is that no writing whatever is required. It is necessary to introduce some device for overdrawn or reserved books.

Besides furnishing the materials for reading, it is now recognized that a public library has also the function of indicating the method of reading and study. A collection of well-chosen books suitable for girls and boys is now a good feature in many English free libraries. At the Providence Public Library, Rhode Island, Mr W. E. Foster issues daily notes on current topics and events, with detailed references by which the subject may be illustrated by the resources of the library; more complete special lists, e.g., on Herbert Spencer, Irish landlord and tenant, &c., are also issued from time to time. Library lectures are now given at several free libraries in England, but, to make these efforts distinctly useful in adding to the good work of the institution, they should be restricted to lectures on books and courses of reading, so that, by illustrating certain works or departments of the library, these lectures may gradually lead readers to a more careful consideration of literature. Aimless and purposeless reading is the bane of a free public library, and it should be the desire of its authorities to do what can be done to induce people to use with due circumspection books of a higher class and of a more useful and informing character. The admirable catalogue of history, biography, and travel of the Boston Public Library, with its suggestive notes and illustrations, had the effect of lowering the reading of fiction from 74 per cent. to 65 per cent. In the same library even the reading of novels has been elevated by the catalogue of English prose fiction arranged on the same plan.

Experience shows that in all that relates to such questions as preliminary for of hours, days and hours of admission, Sunday-opening, access to catalogues, shelves, and librarians, fines, loans of books, guarantees, number of volumes allowed, time of reading, &c., a liberal tendency is always beneficial both to the library and the public.

Precau-  
tions  
against  
fire.

In view of an outbreak of fire, some well considered plan should be fixed upon. Extinguishers and hand-pumps should be kept ready for use in central positions. The means for extinguishing fire should be familiar to the members of the staff, who should all be practised in fire-drill, in order that each may know his proper place and duty in case of emergency. Full directions should be suspended in conspicuous places. In the case of fire breaking out after library hours, it should be thoroughly understood where the keys are to be found, what offenders should be sent for, and what apparatus is ready for use within the building.

Lib-  
rarians.

**Librarians.**—Without insisting upon quite so wide a range of subjects as did F. A. Lert in his *Bildung des Bibliothekars* (Leipzig, 1829), one may expect the librarian of a great library to be a man of liberal education, and specially endowed with sympathy with books and reading, a practical acquaintance with bibliography, including palæography, and bibliology, is also necessary, as well as with the theory and practice of library management. To be thoroughly qualified, a librarian should have had the practical experience of library-work which it is impossible to obtain from any amount of book reading. Besides this, he ought to be a man of business habits and a good administrator.

These acquirements imply qualifications of a somewhat higher

character than in some knowledge of logy, and general person holding the library, however small. As of a popular institution of give the outline of a plan recent Library Association for their (vol. ii.). There should be a preliminary subjects of a sound English education; proficiency in the elements of English literature; proficiency in the elements of one or more classical or modern languages would be specially indorsed upon the certificate, one language to be necessary. The suggested subjects for the preliminary examination are—arithmetic, English grammar and composition, English history, geography, and English literature. After having been engaged in library work for not less than one year, a second-class certificate might be awarded to any librarian or assistant who should pass a satisfactory examination in English literature, especially of the last hundred years, some one other European literature, principles of the classification of the sciences, elements of bibliography, including cataloguing and library management, a cataloguing knowledge of at least two languages besides English to be necessary. A first-class certificate would be given, after a satisfactory examination, to a librarian or assistant of at least two years' experience, for an advanced knowledge of the subjects last mentioned, with the addition of general literary history. A cataloguing knowledge of at least three languages would be necessary for the higher certificate, —an acquaintance with any others, as well as proficiency in any subjects (not more than two in number) offered by the candidate, being specially indorsed.

Women are gradually making their way in libraries. At Manchester and elsewhere they are successfully employed as assistants; and in several other places in England the chief charge of the library is maintained in a very efficient manner by a lady. In the United States the majority of the librarians are ladies (at the Boston Public Library no less than two-thirds of the staff), and many of the most accomplished cataloguers are of the same sex.

The first general meeting of librarians took place at New York, September 15 to 17, 1853, upon an invitation signed by Professor C. C. Jewett, Mr W. E. Poole, and others "for the purpose of conferring together upon the means of advancing the prosperity and usefulness of public libraries, and for the suggestion and discussion of topics of importance to book collectors and readers." About eighty persons attended, many questions were debated, and the suggestion to form a permanent association met with considerable favour. Nothing came of it, however, and twenty-three years had elapsed when, having in view the Centennial Exhibition of 1876, a second meeting was convened on October 4 to 6, at Philadelphia, which was attended by one hundred and two Americans and one English representative. At the Philadelphia conference of 1876, the American Library Association, which has since done so much good work in practical librarianship, was founded. In October 1877 a conference of librarians was held in London, under the presidency of the late Mr J. Winter Jones, and attended by two hundred and sixteen librarians and others, including representatives of the French, German, and Greek Governments, all the chief libraries of the United Kingdom, as well as certain of those of the United States, Belgium, Denmark, France, Italy, and Australia. Altogether one hundred and forty different libraries sent representatives, and nearly the whole field of library-science was reviewed at the different sittings. *The Transactions and Proceedings of the Conference of Librarians* (London, 1878) is the title of the official report of the meeting. The chief result of the conference was perhaps the foundation of the Library Association of the United Kingdom, of which the "main object shall be to unite all persons engaged or interested in library work, for the purpose of promoting the best possible administration of libraries; it shall also aim at the encouragement of bibliographical research, and the association take place at the London members hold an annual conference in some other locality, where the different libraries are inspected, library economy are discussed, and new exhibited. Full reports of these meetings *Monthly Notes* are also issued. Every is now represented in the association members.

**Guides to Selection of Books.**—the best treatises on give respective merits of different editions or copies of the same edition, and or the science dealing with the MSS., and with bibliography, or that their literary aspect, is to be

in all public libraries; but and literature, bibliography, bibliography should be possessed by any administration of any of the librarians. It may be useful to by a committee of the (see *Monthly Notes*, attention being paid to English literature; proficiency in the elements of one or more classical or modern languages would be specially indorsed upon the certificate, one language to be necessary. The suggested subjects for the preliminary examination are—arithmetic, English grammar and composition, English history, geography, and English literature. After having been engaged in library work for not less than one year, a second-class certificate might be awarded to any librarian or assistant who should pass a satisfactory examination in English literature, especially of the last hundred years, some one other European literature, principles of the classification of the sciences, elements of bibliography, including cataloguing and library management, a cataloguing knowledge of at least two languages besides English to be necessary. <sup>1</sup> The article *Bibliography* (the immense extent of this mentioned, reference may be found in the *British Library*, 1877.

will afford a full idea of the library mentioned, reference may be found in the *British Library*, 1877.

necessary to find out Selection. double upon the different states of bibliography, of books and especially with making a library.

On several occasions the United States Congress has passed special Acts directing the exchange of Government publications with those of other countries, and in 1848 the joint committee on the library was authorized to appoint agents for the exchange of books and public documents. As the scheme did not appear to work satisfactorily, the Act was repealed four years later. But since 1867 it is ordered that fifty copies of all documents printed by either the Congress or by any Government department be placed

<sup>1</sup> In the recent *Report of the Royal Commission on Copyright* it is recommended that the privilege should in future be confined to the British Museum alone.

## TABLES OF THE PRINCIPAL LIBRARIES THROUGHOUT THE WORLD.

In compiling the following tables officials of each of the libraries have been personally applied to, and in most instances the information has been supplied by them. An attempt has been made to give particulars of all libraries of general or special interest in the United Kingdom. As regards those of other countries the list has been usually limited to those of 30,000 vols. and upwards, with a few exceptions. In India and the British Colonies there are few collections of that extent.

The abbreviation L. A. in the United Kingdom signifies that the library is under the Public Libraries' Act; o. b. l. means open by leave.

**LIBURNIANS** were a people who at different times were prominent on the Adriatic coasts. They were originally, one cannot doubt, one of the homogeneous Illyrian tribes (see **ILLYRIA**). Living in a barren rocky country along the north-eastern coast of the Adriatic, they devoted themselves to the sea, and were the chief navigators of the Adriatic in the early period. They settled on the coast of Picenum, where the town of Truentum was always counted Liburnian; and the Greek colonists found them at Coreyra and other places. They were pressed on all sides by other races, but were still a powerful people in the time of Scylax (Scyl., p. 7). The islands that lay along the coast were peopled by them and called by their name. They were a race of pirates, who used swift boats with a large sail. These Liburnian ships became famous when the Romans adopted them in several of their naval wars. The heavy and lofty ships that had been developed by the later Greek states proved unequal to the light and swift Liburnian boats. The country was incorporated by the Romans in the province of Dalmatia.

**LIBYA** was a geographical name by which the Greeks usually designated Africa, with the exception of Egypt, although sometimes the continent was thought to be divided between Libya and Ethiopia. Libya enters into the sphere of ancient history only in so far as it came into contact with the civilized races of antiquity, and the present article will

touch this point only: the natural history and the ethnology will be found under other headings (see **AFRICA**). The native tribes came several times into collision with the kings of ancient Egypt. In the reign of Rameses the Great and his successor they invaded the Delta and various expeditions were made by the Pharaohs into the outlying country, on the south particularly (see **EGYPT**). Herodotus mentions one important expedition sent out by Pharaoh Necho (610-594 B.C.), which started from the Red Sea, circumnavigated the continent, and reached the mouth of the Nile after three years' absence. The truth of the tale has often been doubted, but one circumstance in which Herodotus himself expresses his disbelief, viz., that as they sailed west they had the sun on their right hand, has in modern times been generally accepted as proving that the voyage was actually made.

The Phœnician colonies on the north coast, Utica, Carthage, &c., beginning between 1000 and 800 B.C., established a powerful and civilized empire in a hitherto unknown part of Libya. Their trading expeditions gave them a wide acquaintance with the geography of the country, even with the Atlantic coast as far almost as the center of the continent with which the Roman conquerors treated the literature of the Carthaginians allowed not a valuable material to disappear. The historian Sallust, who a praetor of Numidia, was still able to use the ancient records which

he got interpreters to translate for him (Sall., *Jug.*, 17); and fortunately one record of an exploring voyage along the west coast, preserved in a temple in Carthage, was translated by some Greek traveller and is still available (see HANNO). For all that is known of the Carthaginian rule in Libya see CARTHAGE.

Greek mariners must have visited Libya at a very early period, for the edible lotus of the northern coast is mentioned in the *Odyssey*.

In the latter part of the 7th century B.C. the Greeks began to colonize the north coast. Between the Carthaginian territory and the borders of Egypt they planted a number of cities, and the Pentapolis of which Cyrene was the chief was among the richest and most flourishing of all the Greek states (see CYRENE). When the Persians invaded Egypt they made some attempt to extend their empire over Libya; but the expedition of Cambyses (about 525 B.C.) was too unfortunate to encourage them to further efforts. The camel was introduced into Egypt under the Persian rule, and from this time it became easier to make long journeys over the Libyan deserts. Herodotus shows much knowledge of the Sahara, and it is clear that his account must be founded on the reports of traders and caravan guides well acquainted with the desert route. Under the Macedonian kings knowledge of Libya was much extended; they sent exploring expeditions for scientific purposes into Abyssinia, while growing wealth and luxury caused a continually increasing demand for the ivory, spices, and other produce of Libya. In the period 500-200 B.C. it seems certain that commerce was maintained with the countries beyond the Sahara in at least two ways—by the Carthaginian ships trading along the Atlantic coast, and by the overland route across the desert to the Nile. The Roman conquest of Carthage closed the former route. Polybius indeed was commissioned by Scipio to explore the country, and sailed a long way down the west coast; but the Romans themselves had not the maritime enterprise required for such voyages. The record which Polybius wrote for his friend Scipio is quoted by Pliny and Stephanus. Sallust also collected information about the country, and under the emperor Nero an exploring expedition was sent into Abyssinia. The Romans added more to the knowledge of Libya in other ways,—by a better organization of the province and increased facilities of travel and trade, by the frontier wars against surrounding tribes, and finally by the expeditions sent directly into the heart of the country to procure wild animals for the amphitheatre. The passion of the Roman populace for seeing strange animals slaughtered in the public games was gratified by the emperors and magistrates. Enormous numbers of Libyan wild beasts were exhibited in the amphitheatre; even hippopotami and alligators are mentioned. One Roman officer, Maternus, penetrated at least as far as Lake Chad. The *Periplus* of Arrian preserves a record of the trade along the east coast of Libya in the 1st century. In these ways a fairly accurate knowledge of northern Libya was obtained, and Ptolemy could, in the 2d century, construct a good map of Africa as far south as 11° N., though his idea of the shape of the continent further to the south is less accurate than that of Herodotus.

See RATTI, *Libya*, i.; HEYDEN, *Historical Researches*, or in the German *Flora*, vol. ii.; and the geographical works of Forbiger, Kiepert, and others.

LICATA. See ALICATA, vol. i. p. 574.

LICHENS (*Lichenes*) may briefly be defined as cellular perennial plants, furnished with a vegetative system containing gonidia, and with a reproductive system consisting of female theca-sporous fruits and male spermatogamous organs. They constitute a distinct class of cellular cryptogams, intermediate between algae and fungi, to

both of which in some respects they present certain affinities. By the earlier authors they were regarded as being *Aerophyceæ* or terrestrial algae, while of recent years they have been viewed by some writers as being *Ascomycetous* fungi. From both of these, however, they are sufficiently distinguished and separated by the special structure of their thallus, by the presence of certain immediate principles proper to their tissues, and by their mode of life and nutrition. Their relations to these neighbouring classes, and their true systematic place, will be best elucidated on considering their structure and its bearings upon some recent speculations.

#### Structure of Lichens.

A complete lichen consists of a nutritive and vegetative system termed the thallus, and of reproductive bodies borne upon it in the form of *apothecia* and *spermogones*. Occasionally, however, there is no thallus present (e.g., *Sphinctrina*, various *Lecideæ*, *Endococcus*), in which case the fructification is parasitical on the thalli of other lichens.

1. *Vegetative System*.—The thallus is very variable in external form and colour, as also in internal structure.

1. In external form it presents the following modifications. (a) The *foliaceous* thallus, which may be either peltate, i.e., rounded and entire, as in *Umbilicaria*, &c., or variously lobed and lacinated, as in *Sticta*, *Parmelia*, &c. This is the highest type of its development, and is sometimes very considerably expanded. (b) The *fruticulose* thallus, which sometimes is filamentose, as in *Ephelia*, and may be either erect, becoming pendulous, as in *Usnea*, *Ramalina*, &c., or prostrate, as in *Alectoria jubata*, var. *chalybeiformis*. It is usually divided into branches and branchlets, bearing some resemblance to a miniature shrub amongst the *Phanerogaminæ*. An erect cylindrical thallus terminated by the fruit is termed a *podetium*, as in *Cladonia*. (c) The *crustaceous* thallus, which is the most common of all, forms a mere crust on the substratum, varying in thickness, and may be squamose (in *Squamaria*), radiate (in *Placodermis*), areolate, granulose, or pulverulent (in various *Lecanoræ* and *Lecideæ*). In its pulverulent state it is either the rudimentary or the abortive condition of many species. (d) The *hypophæodal* thallus is often concealed beneath the bark of trees (as in some *Verrucariæ* and *Arthoniæ*), or enters *into* the fibres of wood (as in *Xylographa* and *Aggrium*), being indicated externally only by a very thin film or macula. To this may also be referred the evanescent thallus which is denoted solely by gonidia sparingly scattered on the stone or wood (as in some *Calicini* and *Lecideæ*). This is the simplest form under which lichenose vegetation occurs. These two latter forms of thalli may be either *determinate*, i.e., of a definite shape with a distinct margin or boundary, or *effuse*, i.e., spreading extensively over the substratum with no visible limits. The differences in these forms are no doubt connected with differences in the chemical composition of the thallus. In colour also the thallus externally is very variable. In the dry and more typical state it is most frequently white or whitish, and almost as often greyish or greyish glaucous. Less commonly it is of different shades of brown, red, yellow, and black. These various colours do not originate from any colouring matters contained in the cells themselves, but, according to investigations made by Nylander (see *Flora*, 1879, p. 558) they depend upon such as are deposited in the granulations and cellular walls, whence they appear on the epithallus. In the moist state of the thallus these colours are much less apparent, as the textures then become more or less translucent, and the epithallus usually presents the greenish colour of the gonidia (e.g., *Parmelia Borreri*, *Peltidea aphthosa*, *Umbilicaria pustulata*, and pulverulent *Lecideæ*).

2. The internal structure of the thallus presents two principal modifications, viz., the *stratified* thallus, having its different elements (hyphæ and gonidia) arranged in layers, and the *unstratified* thallus, in which these different elements are confused in a homogeneous tissue.

FIG. 1.—Section of Stratified Thallus of *Riccia h. horea*. a, cortical stratum; b, gonidial stratum; c, medullary stratum.

#### A. The stratified thallus.

—On making a vertical section this is seen in a foliaceous lichen to consist of three layers constituting a cortical, a gonidial, and a medullary system, to which in the case of many crustaceous lichens is to be added a fourth, viz., a *hypothalline* stratum.

(a) The cortical stratum occupies the whole of the external surface of filamentous and fruticulose lichens, both the upper and under surfaces of some foliaceous and squamulose species, while it is found only on the upper surface of crustaceous lichens. It usually consists of a colourless cellular tissue, in which the cells are closely compacted and form a pseudo-parenchyma. Its most superficial portion, termed by Nylander the *epithallus*, a sort of cuticle, is amorphous, often more indurated and coloured. In some lichens (e.g., *Collema*) it is the only portion of the cortex present, while in pulverulent crustaceous thalli it is entirely wanting. (b) The gonidial stratum is situated immediately beneath the cortical stratum, and consists usually of greenish spherical cells, or of granules destitute of a cellular membrane. It is not always continuous, but is often interrupted, the gonidia occurring in dissociated masses. Sometimes it is situated on the upper part of the medullary stratum, in which case the gonidia are arranged either between or amongst its exterior elements. In general its limits may readily be distinguished from the others by its peculiar colour. Various important matters relating to the gonidia will more appropriately be afterwards discussed at length. (c) The medullary stratum is more variable in its constituent elements, but, being always colourless, is easily recognized. It presents the three following principal modifications. (α) The *really* medulla consists of simple or branched filaments, which in foliaceous species are loosely interwoven and entangled, and in fruticulose species are more or less conglutinated, assuming a longitudinal direction, and constituting, as in *Usnea*, a kind of solid axis for the support of the thallus. (β) The *cretaceous* medulla occurs only in crustaceous lichens, and is generally characterized by its tawny appearance. It is more compact than the preceding, and consists for the most part of molecular granulations often intermixed with octahedral crystals of lime, and presenting but few traces of filamentous elements. (γ) The *cellulose* medulla consists of a tissue of angular, rounded, or oblong cells containing gonidia in their interior or in their interstices (e.g., *Pannaria*, *Endocarpon*). In some species (e.g., *Ferrucaria fuscata*) the cells have a tendency to reunite into filaments and then to separate again into rows of cells. (d) The *hypothalline* stratum is the inferior one of the thallus and that upon which the other strata are developed, though it is not always visible, and is sometimes entirely wanting. It usually presents itself under a twofold aspect, viz., the *hypothallus* and *rhizome*. (α) The *hypothallus* proper, which is immediately developed upon the prothallus (i.e., the filaments of the germinating spore), is a horizontal stratum consisting of interlacing filaments or of elongated, short, or rounded cells, and is sometimes of a white or whitish colour, but usually dark or blackish. In many crustaceous lichens it is represented only by a black or dark-colored border limiting the thallus (e.g., *Leccidea geographica*, &c.). (β) The *rhizome* consists of vertical rhizoid fibrillæ, usually branching and tufted at their extremities, blackish or greyish in colour, rarely white, which occur on the lower surface of foliaceous lichens. They consist of several filamentous elements which are most frequently articulated and agglutinated (e.g., *Parmelia*, *Physcia*), or sometimes simple and then always articulated (e.g., *Stictis*). It is to be observed that the hypothallus and the rhizome serve merely as bases of attachment for the lichens to the substratum, and do not in any way aid in its nutrition.

B. The unstratified thallus.—This occurs amongst the *Lichenaceæ* (which, however, are most frequently stratified as above), and in

various species belonging to the inferior genera, which have a pulverulent or hypophloidal thallus. In these the constituent elements are more or less mixed together, though the gonidial stratum generally remains distinct, and is often visible when the others are absent. It is, however, the families of the *Byssineæ* and *Collema* that are more especially characterized by an unstratified thallus. Here the cortical stratum is chiefly represented by a greenish (in *Collema*), rarely brown (in *Synalissa*, &c.) non-cellular epithallus, or in others (*Leptogium*) by a thin stratum of angular cells distinct from the other elements of the thallus. The gonidial granules are also disposed in a different manner to those of the *Lichenaceæ*.

In the majority of the *Collema* they are strung together moniliformly, and distributed without order in a gelatinous pellucid substance; while sometimes they are agglomerated into small groups, and situated for the most part next to the epithallus. In *Ephraura* they are not moniliformly arranged, but are tumefacted or involved in a gelatinous cellulose stratum. The rest of the thallus consists of the medullary system (except in *Ephraura*, in which there is no medulla), and is composed of tubular or holofilaments, with roundish cavities containing the gonidial granules, and imbedded in the gelatinous substance, which very readily imbibes water. There are a few lichens in which there is no trace whatever of stratification, as the genus *Cremophora*, in which the entire thallus is composed of filamentous elements, and the peculiar family of the *Muticaceæ*, in which, however, referable to lichens, in which it is very rare throughout.

FIG. 2.—Section of Unstratified Thallus of *Cremophora*, with Moniliform Gonidia scattered amongst the Hyphal Filaments.

In addition to the hyphal and gonidial elements which thus enter into the structure of the thallus, there is another to be noticed, which, however, is to be regarded rather as an immediate principle. This is the *microgonidia*, which are extremely small and in form irregular, being less than 0.002 millim in diameter, and visible only when very highly magnified (300-400 diameters). They occur in all parts of the thallus, especially in the younger cells, from the epithallus to the hypothallus, being especially abundant in the crustaceous species. In the epithallus they are variously coloured according to the colours which it presents, but in all other parts they are colourless. They occur also in the apothecium, the cortex, the thallus, and the spores, and constitute the "microgonidia" of Dr Minks. By the application of a prism and many of them are transformed into small acridin crystals, and in the spores they are frequently acted on by a brownian movement.

We may here also, in connection with the vegetative system of lichens, refer to certain peculiar excrescences which are sometimes presented by the upper or under surface of the thallus. Of these the principal are the following: (1) *Soredia* are pulverulent tufts of the cortical stratum, varying in form, being rounded or disk-like, and either are scattered upon the upper surface of the thallus or border its margins. They are of a lighter colour than the thallus, and consist of a mass of gonidia and of molecular granulations intermingled with filamentous elements. They occur in many fruticulose, foliaceous, and crustaceous lichens, and their position on thallus, the cortical stratum is owing most probably to an excessive development of the gonidial element. Occasionally also they appear on the disk of apothecium in *Leccidea*, where they render abortive, and in this case constitute the *soredia* of *Parmelia* of older authors. When detached from the thallus, they are capable under certain favourable circumstances of giving rise to new plants, and thus act the part of bulbs in the *Leccidea*. It is to be observed by them means that many species which are never found in a fertile state (e.g., *Thamnia atramentaria*, &c.) are propagated. (2) *Cephale* are small, imbricate, pale excrescences which occur abundantly on the under surface of many species of lichens. They are generally naked, but are often also pulverulent or nodiferous.

in which latter case they are called *pseudo-cyphellae*. Their physiological function is not definitely known, but they are most likely connected with the nutrition of the plants. (3) *Isidia* constitute an exuberant addition of some foliaceous and crustaceous thalli. They consist of elevated, coralloid, stipitate excrescences, which are sometimes branched, and which are always of the same colour and texture as the thallus itself. This isidioid condition in crustaceous thalli is the basis of the old pseudo-genus *Isidium*, which is merely an anomalous state of some species of *Pertusaria*. Isidia have the same functions as the soredia, and serve as propagula. (4) *Cyphellae* are orbicular and flattened or globular tubercles of a peculiar texture which occur on the thallus of many species belonging to different genera. They are usually epigenous, as in *Stereocaulon*, *Usnea*, *Lecanora gelida*, *Lecidea parvula*, &c. In a few species, however, they are hypogynous, as in *Peltidea cava* and *Poreocraephella*, while in various *Stictis*, *Nephromopsis*, *Sclidium*, &c., they are endogenous, forming pyrenoid protuberances on the lower surface. Recently Nylander has detected both epigenous and hypogynous cyphellae on *Poroma arvenstrum* and *Lecanora albertina*. They are of a paler colour than the rest of the thallus, from which they are also in structure, being confusely cellulose, and containing gonopores. According to Th. M. Fries (in *Flora*, 1866, p. 19) they are only morbid excrescences caused by algae intruding themselves under the cortex; but this is at once refuted by the fact of their forming constant characters of so many different species occurring in various situations. In these they evidently constitute normal organs, the use of which, however, is unknown.

II. *Reproductive System*.—This consists of *apothecia* or the female organs, of *spermatogones* or the pre-nured male organs, and probably also of *pycnides* or a secondary kind of fructification.

1. The apothecia, like the thallus, are very variable in external form and colour, as also in their internal structure. In external form they present three principal modifications, viz., (1) *disciform* (or gymnocarous), in which the shape is that of a disc (as in all the higher genera); (2) *nucleiform* (or angiocarpous), in which the shape is that of a rounded tubercle with an apical ostiole (as in *Endocarpon*, *Ferocaria*); and (3) *perithecial*, similar in shape to the preceding, but closed, with no ostiole (as in *Thelocarpon*, *Endogocarpus*). The last two are but little variable in figure, and consequently do not in this respect admit of different designations. The disciform apothecia, however, present various shapes, of which the following are the principal:—(a) *plutea*, which are large, rounded, without any distinct thalline margin (e.g., *Usnea*, *Peltigera*); (b) *lecanoria*, or scutelliform, which are orbicular and surrounded by a distinct more or less prominent thalline margin (e.g., *Parmelia*, *Lecanora*), having sometimes also in addition a proper one (e.g., *Thelotrema*, *Ureolaria*); (c) *lecidine*, or patelliform, which are typically orbicular, with only a proper margin (e.g., *Lecidea*), sometimes obsolete, and which are occasionally irregular in shape, angular or flexuose (e.g., *Lecidea juncea*, *L. agnoscina*), or complicated and gyrate (e.g., *Gyrophora*), and even stipitate (e.g., *Baeomyces*); (d) *lirelliform*, which are of very irregular figure, elongated, branched or flexuose, with only a proper margin (e.g., *Xylographa*, *Gyrophora*, &c.) or none (e.g., some *Arthonieae*), and are often very variable even in the same species. It may be here observed that young disciform apothecia are more or less nucleiform. In colour the apothecia are extremely variable, and it is but rarely that they are colourless or subcolorous with the thallus (e.g., *Usnea*, *Baeomyces*). Usually they are discolorous, and may be white, brown, yellowish, or also less frequently rose-coloured, magenta, orange-reddish, saffron, or of various intermediate tints. Occasionally in the same species their colour is very variable (e.g., *Lecanora metachloides*, *Lecidea ciliaris*), while sometimes they are white or glaucous, greenish, pruinose. Lecidine apothecia, which are black, but otherwise variously coloured, are termed *hysteria*.

The two principal parts of which an apothecium consists are the *hypothecium* and the *thecium*.

(1) The *hypothecium*, which corresponds to the *hypothallus*, is the conceptacle of the apothecia. It is composed of cellular tissue, generally very dense, and often presenting an indistinct stratification. This tissue may in general be distinguished from that of the neighbouring parts of the thallus by its cells being smaller, more compact, and differently coloured, though in some instances (as in certain *Papariaceae*) the limits are not determinable. In the apothecia of such genera as *Calicium*, *Baeomyces*, &c., the hypothecium is composed of hollow cemented filaments arranged longitudinally and constricted into a stipe for the support of the fruit. The hypothecium in disciform apothecia is usually termed the *excipulum* proper, while in nucleiform apothecia it is termed the *pyrenium*, and in perithecial apothecia the *peridium*. When the pyrenium quite covers the nucleus it is said to be *entire*, *dimidiate* when it covers only the upper portion. The hypothecium is either colourless or dark, or reddish or yellowish, according as its cells are tinged.

(2) The *thecium*, or as it is more frequently termed the *hymenium*, is that part of the apothecium which contains the organs of the fruit, viz., the *thalamium* and the *thece*, which are placed perpendicularly to the hypothecium. It is penetrated by an amyloid substance, colourless and very greedy of water, termed the *hymenial gelatine*, formed of the lichenine, which becomes bluish or wine-reddish when tinged with iodine. The thecium itself corresponds to the gonidial-membranous stratum, while its superficial portion, termed the *epithecium*, corresponds to the epithallus. (a) The thalamium generally consists of paraphyses which are erect colourless filaments arising from the hypothecium, and whose function is to aid in the expulsion of the spores by the pressure which they exercise upon the thece. They are of nearly equal height, closely placed together, usually very slender, though slightly variable in thickness, frequently articulated, and rarely branched or anastomosing. Internally they are hollow and filled with protoplasm, which sometimes is separated into little globules. Their apices are generally coloured, in most instances dilated, sometimes clavate, and are cemented together by gelatin. They are frequently confused together; occasionally they are but little evolute; while in many of the *Pyrenocarpei* they are entirely wanting, though in these the ostiolar filaments of the hypothecium have sometimes been mistaken for them. (b) The thece are large, oblong, cylindrical or ovoid cells or vesicles containing the spores, and are usually more or less attenuated towards the base. In size and shape they vary considerably in the different genera and species

according to the size, number, form, and arrangement of their spores. They differ also in the same species, within certain limits, according to age, the young thece being more slender than those which are older. In some genera which have very large spores (e.g., *Paraclosterium*, *Pertusaria*) the thece are distended in proportion, and generally present a sacate or oblongo-ventricose form. The theca itself is a thin membranous cell, the walls of which are at first of an equal thickness throughout, but in process of development

FIG. 3. — Vertical Section of Apothecium of *Physcia parietina*. a, paraphyses; b, thece with bilocular spores; c, hypothecium.

they become gradually thinner, except at the summit, where they retain their original thickness. In some species the wall is remarkably thick at the apex (e.g., *Arthonia*), and in others it is invested throughout with a kind of external cuticle (e.g., *Pertusaria*). The thece are ruptured after the expulsion of the spores; though where their walls are extremely thin (as in *Calicium*) they are ruptured and disappear at a very early stage. The spores are the special reproductive organs of lichens, and are produced in the thece by free cell-formation, i.e., by the separation and subsequent condensation of the protoplasm of the fully developed theca around certain points in its interior, corresponding in number to that of the spores to be formed. After the formation of the external spore-wall has taken place, the spores have a definite outline, and may consist of only one cell or loculus (simple spores), or may be divided by one or more transverse partitional membranes (septate spores). Sometimes the loculi are restricted to the two ends or poles of the spore (one in each) and are said to be *polar-bilocular*, the two loculi being occasionally united by a longitudinal tube. At other times the transverse partitions are further divided by several longitudinal partitions, in which case the spore is said to be *mural-divided*, from the resemblance it then bears to the stones in a wall. The contents of the spores are

apices. In size they also vary, though more in length than in thickness, the arcuate spermatia being sometimes very long (0.940 millimetre). These differences in form and size are often very useful in the discrimination of species, just as the two types of the stigmata are sometimes of great service in the distinction of genera. The sper-

in a frequently explicit recognition of the homogeneity of composition, the "smallness" being the formation of a number of specimens are richly provided to the production and ultimately to the maintenance and their position with the mother and their position in the family. The third of the sound of the same but only a better position of the specimens of the apothecary, and the same, and the present. The same, however, and the same, and yet the same, and the same, as suggested by N. V. (1918, p. 10), not exercise any direct influence on the hymenium, but their formation in the prothalline elements of the same, has been found to be distinct (N. V. 1918, p. 10) the result of certain resources, and he supposed that he had detected a new *asporangium* and a *terrestrial* and a *group*. These observations, however, are subject to the same, while his attributing to the specimens, especially calling them "terrestrial" and "group" and not "terrestrial" and "group" observed and of 1918.

3. The pyrenoids are minute, dark-colored pyrenoidan conceptacles which occur on the thallus of various lichens, especially such as are common in the USSR. In external appearance they resemble to some extent the sporangia, from which, however, they at once differ in their internal organization. They consist of simple thin-walled, composed of narrow (often short) cellules, forming a bag bearing on their apical bodies called *stylipores*, which are colourless, usually elongate, but variable in form and size, and filled with orange matter (in part at least they resemble to the spores, and the same fungus produces only a single stylipore, which, unlike the sporangium, has a reproductive property. Their occurrence in lichens was first pointed out by Tulasne, and later on their affinity to certain analogous fruits (*Dibothia*, *Parmelia*, *Septaria*, etc.) in various theca-spored fungi, and regarded them as supplementary or secondarily sporiferous reproductive organs. Considering the number of various *fungi*

(2) The nucleus consists of the *sterigmata* and *sporidia*, and of a mucilaginous substance (the spermiatic gelatin) in the cavity between them, which very greedily imbibes water and aids in the expulsion of the spermiata. Sometimes also there are present in the nucleus a few elongated, articulated, and occasionally branching filaments intermixed with the sterigmata which are operable with the paraphyses of the apothecia (e.g., *Rhizoglyphus*). The sterigmata are elongated cellules filled with a colourless fluid, and are attached to the interior face of the conceptacle growing from it convergently towards the centre, and often nearly filling its entire cavity. They present two important modifications, viz., *simple* sterigmata and *articulated* sterigmata or *arthrosterigmata*, both of which may become somewhat branched. When arrived at maturity they possess the faculty of producing from their apices or also from the articuli the spermiata, one at a time, though many in succession, as may be inferred from the immense number of them lying in the cavity of the nucleus. (b) The spermiata are very small, slender, colourless corpuscles, which at first appear as minute protuberances on the apices of the sterigmatic cells. They subsequently become gradually elongated, and, on reaching maturity, detach themselves from the sterigmata and lie free in the cavity of the nucleus, till in wet weather they are expelled through the ostiole of the sporogones. In form they present two principal modifications, viz., *acicular* and *ellipsoid*, of which the former, the more frequent, is rather variable. They may be slightly fusiform-increasate at one apex (e.g., *Uvaca*), or at both apices (e.g., *Parmelia*), or they may be cylindrical and straight, the most common shape, or cylindrical and arcuate (e.g., *Rhizella*). The spermiata of arthrosterigmata are cylindrical and straight, but slightly thickened and obtuse at the

which frequently occur on lichens, it might be supposed that the pycnides in reality belonged to the same category. From their constant occurrence, however, on the same species, and the evident correlation between them and the accompanying fructifications, as also from the resemblance of their stylospores to the spores of the apothecia, there are good grounds for adopting the conclusion come to by Tulasne. They are very common on the margin of the thallus of isidiiferous states of *Peltigera canina* and *P. rufescens*, where they have often been mistaken for spermogones, which in this genus have not yet been detected. Pycnides occur also in *Leclera vermifera*, and abundantly in *L. tantilla*, in *Halbrothallus*, in several species of *Strigula*, in *Spilonema revertens*, and will probably be yet observed in other lichens.

### The Gonidia of Lichens.

In view of the important place occupied by the gonidia in the structure of lichens, and of the discussions that have recently taken place concerning them, they require to be considered somewhat in detail in order that their real nature and relation to the hyphae, or the thalline filaments, may become apparent. The gonidia are spherical, ellipsoid, or variously rounded cells, with thin, colourless walls composed of cellulose, containing chlorophyll (or a subsimilar colouring matter), homogeneous or granulose, with generally a solid nucleus in the centre. As to the origin of the chlorophyll, it may be observed in passing that this is the same in lichens as in other cryptogamic plants, e.g., mosses and *Hepaticæ*, in which it occurs, the only visible difference being that gonidia often occur as discrete cells. The gonidia increase by binary (very rarely by ternary or quaternary) division, the nucleus also dividing into two portions, each of which forms the centre of a secondary gonidial cell. In the gonidial stratum, where they are arranged between the radicles of the hyphae, their division necessarily proceeds only slowly, but in ecorticated thalli, leprose and others, in which they are free, they are readily multiplied by repeated division. In gonidia isolated from the thallus of some species belonging to *Cladonia*, *Eccrinia*, and *Physcia*, zoospores have been detected by M. Famintzin and M. Boranetzky (see *Ann. Sc. Nat.*, 1868, p. 137), and, although Nylander failed to perceive such in subsequent experiments (*Flora*, 1877, No. 23), he adds that it is possible they may be generated in free gonidia (i.e., in unstratified thalli), which could not be the case in gonidia closely surrounded by thalline filaments. The subject will well repay further investigation. Other matters relating to the character and relations of the gonidia will be best elucidated by considering the forms which they present, and their origin in the thallus.

I. *The Forms of the Gonidia.*—These have been fully treated by Nylander in the *Flora*, loc. cit., where also the first scientific exposition and classification of them have been given. According to the views there propounded, gonidia in their wider acceptance include three very distinct types:—(1) *Eugonidia* (or gonidia proper), which are involved in a distinct cellular membrane, and are usually bright green; (2) *Gonidia* (or the gonidial granules already mentioned), which are naked, pale greenish, glaucous greenish or bluish; and (3) *Gonidimia* (or *Leptogonidia*), which are intermediate between the two preceding, smaller, and of an oblong form. Of these the distinction between eugonidia and gonidia is fundamental, and of "so great weight that lichens seem to present a twofold parallel series" according to the presence of the one or the other in their texture.

These two different anatomical elements, as observed by Nylander, have a certain biological analogy with the blood globules in animals, and similarly afford absolute characters. The principal forms presented by these three kinds of gonidia are the following. 1. *Eugonidia* consist of—(a) *Haplogonidia*, the most frequent, simple, of a protococcoid form, or sometimes glomerulose (as in granulosoleprose thalli); (b) *Platygonidia*, being depressed and variously membranously connated gonidia (*Syngonidia*), as in some foliicolous species (e.g., *Platygramma phyllosema*); (c) *Chroolepogonidia* (or *Chrysogonidia*), containing chlorophyll and orange grains (endochrome) in the same cellule, more or less similar to *Chroolepa* (as in *Gyactea chlorobea*, *Arthonia pruiosa*, *Platygrapha periclea*, *Verrucaria insiliens*, and the genus *Thelopsis*); (d) *Conferogonidia*, somewhat resembling *Conferæ*, and forming the chief element of the thallus of *Cænogonium*. 2. *Gonidimia* are smaller than gonidia proper, with the wall of the cellules less distinct. They occur in *Peltidea*, *Solorina*, and *Nephroma expallidum*. To these belong also *hymenial gonidia*, which are often very minute, and are present in the thallium (destitute of paraphyses) of various *Pyrenocarpei* (e.g., *Verrucaria pallida*, *V. umbrina*, and *V. hymenogonia*), rarely of *Arthonia* as in *A. chroolepida*. 3. *Gonimia* (including the gonimia of *Cephalodia*) consist of—(a) *Haplogonimia*, which are somewhat large (very large in *Phyllicium*), and either simple, or two or several aggregated; (b) *Sirogonimia*, which are scytonemoid or siphonoid gonimia, distinguished by the gonimia being tunicated, and are characteristic of the family *Ephedracei*; (c) *Horrogonimia*, the most common form, smaller, moniliformly arranged, and contained in syngonimia, especially characteristic of the family *Collema*, whence *Collema* (or *Nostoc*) itself, according to Nylander, is to be considered but as a single syngonimium; (d) *Speirogonimia*, which are similar to the preceding, but are not moniliform, with the syngonimia subglobose, smaller and more scattered, as in *Omphalaria* and *Synalissa*. It will be perceived from the above that many of these forms are more or less similar to "gonidioid" algae, though, as we shall presently see, they are not identical with these.

II. *The Origin of the Gonidia.*—By pre-microscopic authors this was a subject necessarily ignored, and indeed it is only within the last thirty years that it has been investigated by lichenists. The earliest theory as to their origin was that propounded by Bayrhafer (*Einiges ub. d. Lichenen und deren Befruchtung*, 1851), confirmed by observations of Speersneider (*Bot. Zeit.*, 1853, &c.), and supported by Schwendener (*Untersuch. ub. d. Flechtenthallus*, 1868). This was to the effect that the gonidia derived their origin from the hyphae (i.e., the thalline filaments), in the way succinctly detailed by M. Fries (in *Scand.*, 1871, p. 7, where it is fully endorsed). "The hypha," he says, "are not only elongated into filaments, but also put forth short branchlets, the terminal cell of which is gradually dilated, becomes subglobose, and is at length filled with chlorophyll (or a subsimilar matter); in a few that (terminal cell) is changed into a gonidium, and then by varied division germinates other gonidia." For several years this theory was accepted at second-hand by most authors who referred to the subject, though a different origin of the gonidia, presently to be noticed, was indicated by the celebrated Tulasne as early as 1862, in his "Mémoire sur les lichens" (*Ann. Sc. Nat.*). The erroneous nature of this theory was well pointed out by Schwendener, who (*Die Algentypen d. Flechtengonidien*, 1869) very correctly affirmed that the actual development of a gonidium from the terminal cell of a hypha had not been observed, though, strange to say, he had previously himself observed this phenomenon. Not being able otherwise to account for the origin of the gonidia, and following up one of two alternatives put forward by De Bary (*Morphology and Physiology of the Fungi, Flechten, &c.*, 1865, p. 291), he promulgated the hypothesis now familiarly known as Schwendenerism. The conclusion to which De Bary came on noticing the resemblance between the gonidia of *Collema* and certain algae was as follows:—"Either the lichens in question," he says, "are the perfectly developed states of plants, whose imperfect forms have hitherto stood amongst the algae, as *Nostoc* and *Chroococcaceæ*, or these latter are typical algae which assume the forms of *Collema*, *Ephedra*, &c., through certain parasitic *Ascomycetes* penetrating into them, spreading their mycelium into the continuously growing thallus, and frequently attached to their phycochrome-bearing cells." Taking this latter suggestion as his starting point, and assuming the identity of certain algal types with the gonidia of lichens, and the identity of the mycelium of fungi with their hyphae, Schwendener extends the said alternative to various other groups of lichens than the *Collema*, and comes to the conclusion that a lichen is composed of a parasitic fungus (the hyphae) and a number of low algae (*Chlorophyllaceæ* and *Phycococcaceæ*), the former of which produces the reproductive bodies and is nourished by the latter. This theory was subsequently expanded and illustrated at length by Bornet (*Recherches sur les Gonidies des Lichens*, 1878), who affirms, as the result of numerous investigations, "that the connexion of the hyphae with the gonidia is of such a nature as to exclude all possibility of the one organ being produced by the other," and that the theory of parasitism can alone explain it satisfactorily. To give any detailed

account of the investigations of these authors, and the arguments by which they endeavour to support the hypothesis, would exceed the limits of the present article, even were all other matters relating to lichens to be excluded. Suffice it to state briefly that, according to Schwendenerism, a lichen is not an individual plant, but rather a community made up of two different kinds of individuals belonging to two distinct classes of cryptogams, viz., a master-fungus and colonies of algal slaves, which it has sought out, caught hold of, and retains in perpetual captivity in order to provide it with nourishment. To such a singular theory, which from its plausibility has met with considerable support in certain quarters, various *a priori* objections of great validity may be taken. Amongst others which have been adduced two may especially be noticed, having reference to the nature of this alleged parasitism, and the situations in which lichens are found. (1) The parasitism described is of a kind unknown in the vegetable kingdom, inasmuch as the host (the *Alga*), instead of suffering any injury, only flourishes the more vigorously. Moreover, the algal slaves being entirely enclosed in the master-fungus, can evidently supply no nourishment to it whatever, while direct observation shows that it is through the surface of the thallus of the lichen that nourishment is conveyed to the gonidial stratum, where the active life chiefly has its seat. (2) As is well known, lichens shun such habitats as are most frequented by algae and fungi, and occur in situations where neither of these are seen. Where then are the algal colonies which, according to the hypothesis, the fungus goes forth in quest of, and "presses into its service"? Either of these arguments is sufficient to throw more than doubt upon Schwendenerism. At the same time, as will be perceived, the origin of the gonidia in the thallus remains to be accounted for, in order that the hypothesis may be utterly subverted. It might at first sight be supposed that this was a matter of no very great difficulty, since by cultivating lichens from the spores it would readily become apparent. All attempts, however, in this direction (and many such have recently been made) have, owing to the peculiar character and conditions of lichen-growth, confessedly proved futile, and the experiments instituted have been productive of no definite results. This is not altogether to be regretted, since in nature itself, when lichens occur on certain substrata, we have in various instances the whole process of the duration of their vegetative system placed before our eyes, from first germinations of the

tion of the cortical stratum advances, its lower portion is resorbed, and the gonidia there become free, giving rise to the gonidial stratum, to the hyphae in which they are not *adnate*, as has been represented, but only adherent by means of the gelatin which penetrates all the elements of the lichen. Often also growing gonidia, young and adult, may be observed in the pseudo-parenchymatous cortical cellules in lichens which in this respect are best adapted for examination, such as *Umbilicaria* (vide Nylander in *Flora*, 1875, p. 303), *Physcia pulverulenta*, *Psoroma hypnorum*, &c. Similarly, with respect to the origin of the gonimia, Nylander observes (*Flora*, 1868, p. 353), that the isidia in the *Collema* (more especially in *Collema*) "show very clearly under the microscope the entire history of the evolution of the thallus from its first origin from a cellule containing a single gonimium to a minute true nostoc, and ultimately to the perfect texture of a *Collema*." With these facts before us, to which various others might be added, such as the entire absence of any algae on pure substrata, where lichen growth presents itself in all its stages, we are compelled to come to the conclusion that the gonidia constitute a true organic system in lichens, and in nature are nowhere seen outside the thallus. Consequently those free algal forms, such as *Pedunculus*, &c., regarded as the free gonidia of lichens, are true algae, there being indeed a parallelism between them but no identity. On the other hand, as to the alleged identity of the lichen-hypha with a fungus-mycelium, it is to be observed that the two are totally different in their nature. The hyphae of lichens (*monothaphae* of Nylander) are rigid, elastic, containing helmin, not becoming putrid by maceration, with no faculty of penetrating or involving, while the hyphae of fungi are caducous, soft, flexible, with thin walls, &c. Hence, as there is no algal in the lichen, so neither is there any fungus, though there is a parallelism between the fructification of lichens and the asciferous section of fungi (Crombie in *Pop. Sc. Rev.*, 1874).

#### Nutrition and Life of Lichens.

As already intimated, lichens derive their nourishment directly from the atmosphere, in the shape of rain (or dew) with the materials contained in it. Here, as elsewhere, water is the condition of life, and through its medium is conveyed to them the nutrient substances requisite for their existence and growth, from the clouds, from rivers, and, in the case of maritime species, even from the sea. Where, however, the atmosphere is impregnated with smoke, soot, or other deleterious ingredients, lichens will not grow nor flourish. Hence in our larger cities, or even in smaller manufacturing towns, scarcely any lichen vegetation, or none whatever, is seen. Even in their more immediate suburban districts they occur only in a gonidial or rudimentary state, constituting the pseudo-genus *Leparia* of the older botanists, and increasing through long periods by bisection, but never developing into perfect plants. Indeed it is now a well-known fact that their fully developed condition is a sure indication of the purity of the air and the salubrity of the districts in which they occur. It has sometimes been stated that they draw some portion at least of their nutriment from the substratum to which they are affixed. For this, however, their structure is by no means well adapted, and such inorganic substances as iron and lime, which enter into their composition, are only as if mechanically derived in solution from the substratum. This in very many instances, e.g., bare quartzose rocks, dead sapless wood, and pure naked glass, can evidently supply no nutriment whatever. Moreover, in the case of crustaceous species, such as *Lecanora tartarea*, &c., and also of terricole fruticulose species, such as *Cetraria islandica*, &c., the portion of the thallus next to the substratum is dead, so that no nutrient substances can be conveyed through it to the upper layers of the thallus. A very simple, but at the same time convincing, illustration of this is adduced by Nylander. "By immersing," he says, "any fruticulose thallus, such as *Usnea*, by the base in water, it remains entirely dry (with the exception of the part submerged), but if water be poured over the other portions, it quickly absorbs it, softens, and revives." The same thing may be seen in nature itself, in the case of such species as *Cladonia rangiferina*, *Alectoria chroleuca*, *Platysma nivale*, &c., growing on temporarily wet substrata,

FIG. 6.—Hypothalline condition of *Lecanora cinerea*, showing the origin of the first Cortical Gonidiogenous Cellules. (After Tulasne.)

incontrovertibly demonstrates that the gonidia originate, not from the filaments themselves, but in the cellules of the first cortical glomerules which are produced upon the young hypothallus. This may very easily be studied in the earlier stages of development of crustaceous lichens growing on pure quartz rocks (e.g., *Lecidea geographica*), on the smooth bark of young trees (e.g., *Lecanora subfusca*), and more especially on the surface of old glass (e.g., *Lecanora galactina* and *Lecidea albotra*). In the case of the young thalli of *Lecanora cinerea* this was sufficiently well delineated by the celebrated Tulasne in 1852, the year subsequent to the promulgation of the Bayrhorffian theory, in his elaborate "Mémoire sur les Lichens," pl. III. f. 3. Afterwards, as the evolu-

when the base of their thalli is soft and moist, and all the rest dry and rigid. It cannot therefore be doubted that the nutritive elements contained in the rain or other water are conveyed to the lichen through the surface of the thallus. It is in the superficial parts also, as Nylander has well observed (in *Flora*, 1874, No. 4), that "the active life has its seat, chiefly around the gonidia, manifesting itself in the putting forth of young parts (lobes, luciniae, branches, isidia), and in the functions of the apothecia and the spermogones, so that the nourishing humours necessary for all the actions of life are especially and directly poured upon these." The vital activities, however, in lichens thus nourished are, as might be expected from the nature of the source whence their nutriment is derived, very intermittent, and in dry weather cease to operate, and become entirely dormant. Hence their life, unlike that of all other plants, is twofold, viz., one *active*, in which when moistened all the vegetative and reproductive functions are at work, and the other *passive*, in which when dry these functions are completely in abeyance. For such a peculiar duplex existence, at one time vegetating, at another lethargic, their organization in all its parts, gonidial and otherwise, is admirably adapted. More especially is this the case with respect to the lichenine found in their textures, which, being readily dried and as readily moistened, enables them to resist with impunity the greatest extremes of temperature, alternate periods of drought and wet, the scorching heat of the sun, the vehemence of stormy winds, and the nipping frosts of winter.

In this fitful and abnormal life of lichens we have the explanation in a great measure of their almost indefinite duration of existence. It is well known that they are perennial plants in the widest sense of the term, and that, though in the earlier stages of their existence their growth is comparatively rapid, yet this becomes extremely slow when they arrive at a certain age. The time required for the development of even the most rapidly growing species may be calculated by the appearance of such of these as are met with on gravestones, mortar of houses, stone walls, wooden palings, and such like, the date of whose erection is known. Amongst other instances which have come under the present writer's own observation may be adduced the case of *Physcia parietina*, growing in fair quantity on the stones of a granite wall built in 1836 in a maritime district where the plant is extremely abundant, and where atmospheric and other conditions are well suited for its growth. In a recent visit to the spot it was found that, although the thallus is now well developed, no fructification whatever is visible, though traces of spermogones are beginning to appear, so that in the space of forty-five years this plant has not yet attained full maturity. But slow as is the growth of lichens after a certain stage of their development, their tenacity of life is very remarkable, as might *a priori* be inferred from their capacity of enduring without injury the greatest extremes of temperature and of hygrometrical conditions. It is on record that, after the lapse of nearly half a century, the same specimen on the same spot of the same tree has been observed without any change in its condition. On this point also E. Fries (in *L. E.*, p. xlv.) notices that certain species such as *Physcia ciliaris*, kept in houses for upwards of a year, revive when again exposed to the influences of the atmosphere,—an observation which in the case of *Urbina vagitferina* similarly kept for a still longer period the present writer can fully corroborate. Endowed then with this singular intermittent vitality, we can easily understand how many individuals which occur on hard mountainous rocks or on the trunks of aged trees in ancient forests are in all probability many hundreds of years old. Nor does age seem in any way to weaken their fecundity, even when the

thallus has apparently ceased to grow. This, as observed by Nylander (in *Syn.*, p. 5), is shown from the circumstance that were it otherwise "the already old fruits would be destitute of spores, which is never the case," unless in plants of some lower tribes, e.g., *Graphidei* and *Verrucariae*, in which the thallus is but sparingly gonidiose, and the life consequently is shorter. In other instances the central portion of the thallus sometimes normally perishes in old plants, as in *Pterygium centrifugum*, *Collema melanum*, *Parmelia centrifuga*, and *P. saxatilis*, leaving only peripheral circles, in which, however, the life of the individual still continues for ages. In fact, "the life of lichens bears in itself no cause of death, and is only to be ended by external injuries" (E. Fries, *L. E.*, loc. cit.), or by the alteration of climatic and atmospherical conditions. Hence the assumption is not unwarrantable that individuals of such confessedly long-lived species as *Lecidea geographica*, growing on rocks upon the summits of lofty mountains, date from more than "fabulous epochs," and probably outrival in longevity the ages assigned to the oldest trees on the surface of the globe.

#### Chemistry of Lichens, and Chemical Reactions.

*Chemistry of Lichens.*—This is still but little understood, notwithstanding that the subject has been more or less investigated by authors. Their examinations, however, have been too limited and desultory to enable us to give any detailed account of the different principles which enter into the composition of the lichen tissues. Moreover, with respect to those species which have been more particularly analysed, they have sometimes employed not only the same terms in different senses, but also different terms to denote the same substance. There can, however, be no doubt that the chemical composition of lichens not only produces great modifications in their form, but also considerable diversities in their properties.

The principal substance which occurs in lichens, especially in such as are foliaceous and fruticulose, is *lichenine*—a special kind of gelatin peculiar to them. It is intermediate in character between dextrin and starch, and very eagerly imbibes water, though if boiled in water it is dissolved and lost. Starch also very rarely occurs in large lenticular grains scattered in the tissues. In crustaceous lichens *ovulate* of lime predominate, and forms a large proportion of the thallus, e.g., 65 per cent. in *Lochnora esculenta* according to Geibel. *Chlorophyll* and its modification *phycochrome* are found in lichens only in relatively small quantities, as is also the case with most of the other principles they present. These are enumerated by Nylander (in *Syn.*, p. 51) according to the affinities they bear, as follows:—(1) phosphate of lime, sea-salt, manganese, iron; (2) picrochenine, variolarine, orceine, cetrarine, inuline, erythrine, rocelline, picroerythrine; (3) gyrophoric acid, pareillic acid, usnic acid, orceic acid, erythrinic acid; (4) sugar not crystallizable, oil, waxy matter, resinous matter. Several others, especially phosphates and acids, have been enumerated by authors, which in some instances have not been corroborated, and in others are doubtfully distinct. In illustration of the manner in which several of these principles enter into the composition of lichens, we may adduce the analyses given in one or two species which have been more fully subjected to experiment. In *Cetraria islandica* there have been detected starch, including lichenine and inuline, to the extent of 80 per cent.; gummy and waxy matters; a bitter principle, *cetraric acid*; a fatty principle, *lichenic acid*; *sumaric acid*, which exists also in *Parmelia officinalis*; *gallic acid*, the astringent principle of galls; uncrySTALLIZABLE sugar; various salts, such as *bisulphate of potash*, and *tartrate and phosphate of lime*. Again, in *Physcia parietina* there have been found several alimentary principles, as *gliadine*, *starch*, *sugar*, *gum*; several medicinal substances, as *resin*, *bitter matter*, *gallic acid*, and a peculiar etheral oil; a yellow colouring matter called *chrysophanic acid*; also *wax*, *stearine*, and some salts, as *carbonate of lime*. The ash of lichens is said to constitute from 8 to 10 per cent. of their bulk, and consists of various earthy bases, such as potash, soda, lime, magnesia, alumina, silica, manganese, and peroxide of iron, in combination with various acids, such as carbonic, phosphoric, sulphuric, and hydrochloric. The whole subject, however, of the chemistry of lichens requires to be investigated in a more extensive and methodical manner than has hitherto been done either by chemists or lichenists.

**Chemical Reactions in Lichens.**—These have reference to the thallus and the apothecia, and in both respects afford valuable assistance in the systematic study of lichens. (a) *Thalline* reactions depend upon the presence in the thallus of certain colourable materials in the form of acids, and are manifested on the application of hydrate of potash and the hypochlorite of lime either on the cortical stratum or the medulla. Of these reagents, hydrate of potash (K), composed of equal weights of caustic potash and water, and hypochlorite of lime (CaCl), composed of chloride of lime and water of any strength, may give certain reactions or none, according to the presence or absence of particular acids in the thallus. If no reaction takes place, this is denoted by K—, CaCl—, and similarly if there is reaction by K+, CaCl+. A very convenient mode of symbolizing the positive and negative reactions of the cortical layer and the medulla of the same species is to place the reaction of the former above the latter, e.g., K±, CaCl±, denoting that with K the cortical stratum shows reaction and the medulla none, while with CaCl the cortical stratum gives none, but the medulla a distinct reaction. Again, there is often no reaction produced by K alone, but if CaCl be added to it while still moist, a decided reaction appears, for which K(CaCl)± is the symbol; or, on the other hand, the reaction given by K may be neutralized by the immediate application of CaCl, in which case it is expressed by K+(CaCl)—. The positive reactions are due to the presence of particular acids in the thallus, such as *crocinic* acid giving a crimson reaction with CaCl, *chrysophanic* acid giving a purple reaction with K, *glauconic* acid giving a yellow reaction with CaCl, and *lecanoric* acid giving a citrine reaction with K. In most cases where the natural colour of the thallus (often also of the medulla) is yellow or orange, *chrysophanic* acid is present, and with K gives a purple reaction (e.g., *Physcia lichina*), but in others externally similar in colour and general appearance, where only *lethophanic* acid is present (e.g., *Lecanora lethocarpa*), K gives no reaction whatever. Sometimes K produces at first a yellow colour which immediately changes into a red or purple, as in *Lecanora cinerea*, which at once enables us to distinguish it from the closely allied species *L. gibbosa* and *L. calcarea*. A solution of iodine (I) is also in certain cases useful as a test on the medulla, and in the discrimination of some species of *Collema*. The value of these chemical tests in lichens was first pointed out by Nylander in *Flora*, 1866, pp. 223, 224, was subsequently illustrated by him in *Flora*, 1869, *passim*, in the case of species belonging to various genera, and has since been generally acknowledged by lichenists and employed by them in all specific diagnoses. They are unquestionably most important, not only in the discrimination of many difficult and closely allied species, but also in enabling us to refer with certainty varieties to the species to which they properly belong. Nay, even a small fragment of the thallus, whether sterile or fertile, may by their aid be readily determined, while otherwise it would be either quite indeterminate or doubtful. Generally they may be obtained on any portion of the thallus, but they are frequently more vivid, as might be expected, in the growing or circumferential portions. It is, however, only immediate reactions which depend on the colouring matter contained in the cortical stratum and the medulla that are to be attended to, and not secondary or tardy reactions which may otherwise originate, e.g., from the dissolution of the chlorophyll of the gonidia. At the same time it is to be observed, in order to prevent a misconception which has occasionally been entertained, that they do not *per se* constitute a special specific character, but only an additional and confirmatory specific character. As such their value is clearly apparent in cases where the external characters are similar or approximate, and doubt necessarily exists as to their specific value. (b) *Apothecial* reactions for the most part take place either externally on the epithecium or internally on the hymenial gelatin. The reactions of the epithecium are generally produced by K on species which have yellow or orange apothecia (e.g., *Lecanora aurantiaca*, *Lecidea leucocaulata*), while others with concolorous apothecia (e.g., *Lecanora epurata*, *Lecidea lucida*) give no reaction whatever, owing to the presence or absence of *chrysophanic* acid. In certain cases also the reaction with CaCl is very useful in enabling us to separate closely allied species with similar apothecia, e.g., *Lecanora subcarnaria* (epithecium CaCl—) from *L. glaucoma* (epithecium CaCl+yellow). Again, with respect to the reaction of the hymenial gelatin, this, as already observed, depends on the application of a solution of iodine. The formula by which the solution is to be prepared is—iodine, gr. j.; iodide of potash, gr. iij; distilled water, ½ ounce. In most lichens, where the spores are mature, this solution will tinge the hymenial gelatin in some cases only blue, in others at first blue and then wine-red, and in others wine-red or tawny wine-coloured only, without any preceding blue tinge. In such instances the reaction obtained is often very useful as a confirmatory specific character. Sometimes, however, the blue reaction takes place only on the thecæ (e.g., *Pertusaria*, *Ph. Thelotrema*, &c.). In the case of some species belonging to the inferior genera the reaction with I is especially valuable for the assistance it lends in distinguishing them from certain pyrenomy-

cetous fungi, to which otherwise they might be supposed to belong. True, in some fungi (e.g., *Periza*) we obtain a reaction with I, and in some lichens we have no reaction visible; but otherwise in such exceptional instances their respective anatomical characters readily show to which class they belong.

#### Economic Uses of Lichens.

These are intimately connected with their chemical constituents, and are in some respects very important. In the arts, as food and as medicine, many of them have been highly esteemed, though others are not now employed for the same purposes as formerly.

1. *Lichens Used in the Arts.*—Of these the most important are such as yield, by maceration in ammonia, the valuable dyes known in commerce as archil, cudbear, and litmus. These, however, may with propriety be regarded as but different names for the same pigmentary substance, the variations in the character of which are attributable to the different modes in which the pigments are manufactured. Archil proper is derived from several species of *Rocella* (e.g., *R. Montagnei*, *R. tinctoria*), which yield a rich purple dye and fetch a high price in the market. Of considerable value is the "pebble" prepared from *Lecanora parvella*, and much used in the preparation of a red or crimson dye. Inferior to this is "cudbear," derived from *Lecanora tartarea*, which was formerly very extensively employed by the peasantry of north Europe for giving a scarlet or purple colour to woollen cloths. By adding certain alkalies to the other ingredients used in the preparation of these pigments, the colour becomes indigo-blue, in which case it is the litmus of the Dutch manufacturers. Amongst other lichens affording red, purple, or brown dyes may be mentioned *Romulea scopulorum*, *Parmelia saxatilis* and *P. aspera*, *Umbilicaria pustulata* and several species of *Gyrocampa*, *Urocledaria scruposa*, all of which are more or less employed as domestic dyes. Yellow dyes, again, are derived from *Cladonia vulpina*, *Platysma juniperinum*, *Parmelia caperata* and *P. conspersa*, *Physcia glaucans*, *Ph. parvella*, and *Ph. lychnis*, though like the preceding they do not form articles of commerce, being merely used locally by the natives of the regions in which they occur most plentifully. In addition to these, many exotic lichens, belonging especially to *Parmelia* and *Sticta* (e.g., *Parmelia lasiocarpa*, *Sticta argentea*), are rich in coloring matter and, if obtained in sufficient quantity, would yield a dye in every way equal to archil. These pigments primarily depend upon special acids contained in the thalli of lichens, and their presence may readily be detected by means of the reagents already noticed. In the process of manufacturing, however, they undergo various changes of which the chemistry is still but little understood. At one time also some species were used in the arts for supplying a gum as a substitute for gum-arabic. These were chiefly *Rocella fuciformis*, *Evernia prunastri*, and *Parmelia physodes*, all of which contain a considerable proportion of gummy matter (of a much inferior quality, however, to gum-arabic), and were employed in the process of lico printing and in the making of parchment and candles. In the 17th century some filamentose and fruticose lichens, viz., species of *Usnea* and *Ramalina*, also *Evernia furfuracea* and *Chodina ramulifera*, were used in the art of perfumery. From their supposed aptitude to imbibe and retain odours their powder was the basis of various perfumery, such as the celebrated "Poudre de Cypre" of the Languedociers, but their employment in this respect has long since been abandoned.

2. *Nutritive Lichens.*—Of still greater importance is the capacity of many species for supplying food for man and beast. This results from their containing amylaceous substances, and in some cases a small quantity of saccharine

matter of the nature of manna. One of the most useful nutritious species is *Cetraria islandica*, "Iceland moss," which, after being deprived of its bitterness by boiling in water, is reduced to a powder and made into cakes, or is boiled and eaten with milk by the poor Icelanders, whose sole food it often constitutes. Similarly *Cladonia rangiferina* and *Cl. sylvestica*, the familiar "reindeer moss," are frequently eaten by man in times of scarcity, after being powdered and mixed with flour. Their chief importance, however, is that in Lapland and other northern countries they supply the winter food of the reindeer and other animals, who scrape away the snow and eagerly feed upon them. Another nutritious lichen is the "Tripe de Roche" of the Arctic regions, consisting of several species of the *Gyrophorei*, which when boiled is often eaten by the Canadian hunters and Red Indians when pressed by hunger. But the most singular esculent lichen of all is the "manna lichen," which in times of drought and famine has served as food for large numbers of men and cattle in the arid steppes of various countries stretching from Algiers to Tartary. This is derived chiefly from *Lecanora esculenta*, which grows unattached on the ground in layers from 3 to 6 inches thick over large tracts of country in the form of small irregular lumps of a greyish or white colour. Speaking of the distribution of these nutritive lichens, whose qualities depend on the presence of amylaceous matter, Dr Lindsay (in *Pop. Hist. Brit. Lich.*, p. 82) very appropriately remarks that, "by a beautiful provision of nature, they occur precisely under the circumstances where they are most wanted—in northern or arctic countries, or on arid steppes, where grain stuffs are unknown, and food of a better kind is often scarce or deficient." In connexion with their use as food we may observe that of recent years in Scandinavia and Russia an alcoholic spirit has been distilled from *Cladonia rangiferina* and extensively consumed, especially in seasons when potatoes were scarce and dear. Formerly also *Sticta pulmonaria* was much employed in brewing instead of hops, and it is said that a Siberian monastery was much celebrated for its beer which was flavoured with the bitter principle of this species.

3. *Medicinal Lichens*.—During the Middle Ages, and even in some quarters to a much later period, lichens were extensively used in medicine in various European countries. Many species had a great repute as demulcents, febrifuges, astringents, tonics, purgatives, and anthelmintics. The chief of those employed for one or other, and in some cases for several, of these purposes were *Cladonia pyxidata*, *Usnea barbata*, *Ramalina farinacea*, *Ecclesia prunastri*, *Cetraria islandica*, *Sticta pulmonaria*, *Parmelia saxatilis*, *Physcia parietina*, and *Pertusaria amara*. Others again were believed to be endowed with specific virtues, e.g., *Peltigera canina*, which formed the basis of the celebrated "pulvis antilyssus" of Dr Mead, long regarded as a sovereign cure for hydrophobia; *Platysma juniperinum*, lauded as a specific in jaundice, no doubt on the *similia similibus* principle from a resemblance between its yellow colour and that of the jaundiced skin; *Peltidea aphthosa*, which on the same principle was regarded by the Swedes, when boiled in milk, as an effectual remedy for the *aphthæ* or rash on their children. Almost all of these virtues, general or specific, were imaginary; and at the present day, except perhaps in some remoter districts of northern Europe, only one of them is employed as a remedial agent. This is the "Iceland moss" of the druggists' shops, which is undoubtedly an excellent demulcent in various dyspeptic and chest complaints. Probably also *Pertusaria amara*, from the intensely bitter principle which it contains, might still with propriety be employed as a febrifuge. No lichen is known to be possessed of any poisonous properties, although *Chlorea vulpina* is believed by the Swedes to be

destructive to wolves when powdered and "mixed with pounded glass." Nor are lichens, as has sometimes been alleged, injurious to the trees upon which they grow, except to a very limited extent. Not being parasites properly so called, the only injury they can inflict upon them is by slightly interfering with the functions of respiration, or, when growing very crowdedly upon the branches of orchard trees, by checking the development of buds.

#### Classification of Lichens.

From the time of Acharius, the father of lichenological science, different authors have proposed different classifications of lichens, according to the degree of importance attached by them to one or other of their vegetative and reproductive organs. Most of these classifications, however, whether proposed by microscopical or pre-microscopical lichenists, have been too artificial and arbitrary, and indeed less natural in various ways than that originally propounded by Acharius. Of recent years they have been entirely superseded by other two systems, viz., that of the Massalongo-Koerberian and that of the Nylanderian school. With respect to the former of these, its characteristic feature is the prominence which it assigns to the form and structure of the spores not only in the differentiation of species but also in the foundation of genera. Though it has been adopted, with various modifications, by many Continental lichenists, yet essentially it also proceeds on an artificial principle, and necessitates the adoption of far too many genera, distinguished from each other merely by slight differences in the spores. The other system—that of Nylander, which was first proposed by him in his *Essai d'une Nouvelle Classification des Lichens* (1854–55),—has since then commended itself more and more to the acceptance of lichenists, so that even the disciples of the opposite school (the sporologists) have in many respects gradually approximated towards it in their most recent writings. Not only is it the only complete system of classification yet wrought out; it is also the most natural and philosophical of any hitherto propounded. In its main outline it proceeds upon the principle of showing the near relation of certain lichens to some genera of algæ on the one hand, and of certain other lichens to some genera of fungi on the other hand, and connects these three great classes of cryptogams together by a sort of twofold chain, commencing with those genera of lichens nearest allied to the algæ, working up to those genera best developed (*Stictæ*), and thence retrograding and terminating with those nearest allied to the fungi. His genera also are principally founded, not upon a single special character, but upon the combined anatomical characters presented by the thallus, the apothecia, and the spermogones. It may here be further observed that we are indebted to the same accomplished lichenist for the succinct but comprehensive diagnoses, generic and specific, of the different parts of a lichen, which have tended so much to facilitate their systematic study. The following is a conspectus of the Nylanderian classification of lichens, with the leading characters of the different families and tribes, and an enumeration of all the principal genera of which these are composed.

#### Family I.—*Ephedacei*, Nyl.

Thallus but little turgid when moist, gonidial stratum consisting of gonimia which are tunicated; medullary filaments none.

Tribe 1. *Sironiphei*, Nyl.—Thallus filamentoso-fruticulose, gonimia variously connate. Apothecia biatorine or lecideine. Spermogones with sterigmata or arthrosterigmata.

Genera: *Sironisphon*, Ktz.; *Gonionema*, Nyl.; *Spilonema*, Born.

Tribe 2. *Pyrenopsci*, Nyl.—Thallus thinly granulose, rubricose within, gonimia simple or connate. Apothecia lecanorine or pyrenocarpeous. Spermogones with simple sterigmata.

Genera: *Euopsis*, Nyl.; *Pyrenopsis*, Nyl.

Tribe 3. *Homopsidii*, Nyl.—Thallus either fruticulose with the gonimia seriated, or squamuliform or granulose with the gonimia subsolitary. Apothecia pyrenocarpous with or without paraphyses. Spermatogones with simple sterigmata.

Genera: *Ephaba*, Fr.; *Ephabeta*, Nyl.; *Phylliscum*, Nyl.; *Phylliscodinium*, Nyl.; *Collempsidium*, Nyl.

Tribe 4. *Magnopsii*, Nyl.—Thallus pyrenopsidian, containing syngonimia, the gonimia arranged without order. Apothecia peridieine.

Genus: *Magnopsis*, Nyl.

#### Family II.—*Collema*cei, Nyl.

Thallus turgid when moist, gonidial stratum consisting of gonimia moniliformly arranged; medulla not discrete.

Tribe 1. *Lichini*, Nyl.—Thallus fruticulose or radiately lacinated, gonimia elongato-seriately moniliform, subconnate. Apothecia lecanorine or lecideine. Spermatogones with sterigmata or arthrosterigmata.

Genera: *Lichina*, Ag.; *Pterygium*, Nyl.; *Leptogidium*, Nyl.; *Lichinodinium*, Nyl.

Tribe 2. *Collema*, Nyl.—Thallus membranaceous, lobate, rarely fruticulose, granulose or subsquamulose, gonimia moniliformly arranged, cortical stratum none or distinct. Apothecia lecanorine or rarely pyrenocarpous. Spermatogones with simplish sterigmata or arthrosterigmata.

Genera: *Lecophysma*, Fr. fil.; *Synalissa*, DR.; *Omphalaria*, DR.; *Anema*, Nyl.; *Paulia*, Fee; *Schizoma*, Nyl.; *Collema*, Ach.; *Leptogium*, Ach.; *Ramulotium*, Nyl.; *Lichinella*, Nyl.; *Anphidium*, Nyl.; *Collempsis*, Nyl.; *Hydrothysia*, Russ.

Tribe 3. *Pyrenidii*, Nyl.—Thallus abruillose, gonimia moniliformly coherent, cortical stratum distinct. Apothecia pyrenoid.

Genus: *Pyrenidium*, Nyl.

#### Family III.—*Lichen*acei, Nyl.

Thallus not gelatinous, with a gonidial, rarely gonimic stratum; medullary stratum more or less distinct.

##### Series I.—*Epicnidi*cei, Nyl.

Apothecia with the spores usually naked and pulverulent on the surface of the fructification.

Tribe 1. *Calicie*, Nyl.—Thallus horizontally expanded, sometimes none. Apothecia stipitate, capituliform or sessile. Spermatogones with simple sterigmata.

Genera: *Sphinctrina*, Fr.; *Calicium*, Pers.; *Stenocybe*, Nyl.; *Conocybe*, Ach.; *Pygidium*, Nyl.; *Trachylia*, Fr.; *Pyrgillus*, Nyl.

Tribe 2. *Tylophori*, Nyl.—Thallus thin crustaceous. Apothecia at first pyrenoid and then lecanorine with sporal mass. Spermatogones with somewhat branched sterigmata.

Genus: *Tyloporon*, Nyl.

Tribe 3. *Sphaerophori*, Nyl.—Thallus fruticulose, branched. Apothecia at first nucleiform, becoming variously dehiscent, with sporal mass. Spermatogones with simplish sterigmata or arthrosterigmata.

Genera: *Sphaerophoron*, Pers.; *Terrosophus*, Lev.; *Tholurna*, Norm.

##### Series II.—*Cladoni*cei, Nyl.

Apothecia terminal on podetia, rarely sessile, biatorine or rarely lecanorine.

Tribe 4. *Baeomycetei*, Nyl.—Thallus horizontally expanded. Apothecia substipitate. Spermatogones with sterigmata or arthrosterigmata.

Genera: *Gomphillus*, Nyl.; *Baeomyces*, Pers.; *Glossodium*, Nyl.; *Thysanothecium*, Berk.; *Stereocauliscum*, Nyl.

Tribe 5. *Pilophori*, Nyl.—Thallus granulose, cephalodiferous, with rigid podetia. Apothecia cephalodine, on the podetia, with the paraphyses prolonged into the hypothecium. Spermatogones with simplish sterigmata.

Genus: *Pilophoron*, Tuck.

Tribe 6. *Stereocauli*, Nyl.—Thallus caespitose, podetiiform, solid. Apothecia terminal or lateral, lecideine or rarely lecanorine. Spermatogones with simple sterigmata.

Genera: *Stereocaulon*, Schreb.; *Stereocladium*, Nyl.; *Argopsis*, Fr. fil.; *Oxocladium*, Mnt.

Tribe 7. *Cladoni*cei, Nyl.—Thallus foliaceus or fruticulose, with fistulose podetia. Apothecia biatorine on the podetia, rarely sessile on the leaflets. Spermatogones with simplish sterigmata.

Genera: *Heterodea*, Nyl.; *Pycnothelia*, Ach.; *Cladonia*, Hoffm.; *Cladina*, Nyl.; *Cladia*, Nyl.; *Ramulca*, Nyl.

##### Series III.—*Ramalodi*cei, Nyl.

Thallus effoliosole, fruticulose, or filamentose. Apothecia generally lecanorine.

Tribe 8. *Roccellet*, Nyl.—Thallus simplish or branched, internally with filamentose medulla. Apothecia irregular (normally lecanorine), adnate, terminal, or lateral. Spermatogones with simplish sterigmata.

Genera: *Combea*, DN.; *Roccella*, DC.

Tribe 9. *Siphulei*, Nyl.—Thallus podetiiform, simple or fruticulose, internally with filamentose or fistulose medulla. Apothecia unknown. Spermatogones (where seen) with arthrosterigmata.

Genera: *Siphula*, Fr.; *Endocena*, Cromb.; *Thamnolia*, Ach.

Tribe 10. *Ramalina*cei, Nyl.—Thallus fruticuloso-foliaceous, rounded or compressed, with woolly medulla. Apothecia lecanorine, scutellate. Spermatogones with arthrosterigmata.

Genus: *Ramalina*, Ach.

Tribe 11. *Usacei*, Nyl.—Thallus much branched, rounded, or compressed, with firm medullary axis. Apothecia parmelioid, peltate. Spermatogones with simplish sterigmata.

Genera: *Usua*, Hoffm.; *Neurogonum*, N. and Fl.; *Chlorra*, Nyl.

Tribe 12. *Alcatorii*, Nyl.—Thallus branched, rounded, or compressed, with woolly medulla. Apothecia parmelioid, scutelliform. Spermatogones with simplish sterigmata or arthrosterigmata.

Genera: *Alcatoria*, Ach.; *Dactyloa*, Nyl.; *Dufauria*, Ach.

Tribe 13. *Citrici*, Nyl.—Thallus fruticulose or foliaceous, with woolly medulla. Apothecia parmelioid, marginal, obliquely affixed. Spermatogones with simple sterigmata or arthrosterigmata.

Genera: *Citricia*, Ach.; *Platysma*, Hoffm.

##### Series IV.—*Phallobi*cei, Nyl.

Thallus foliaceus, usually depressed, lobate. Apothecia generally peltiform or lecanorine.

Tribe 14. *Parmelia*cei, Nyl.—Thallus frondosely dilated, or lobate, or lacinated, with woolly, rarely solid, medulla. Apothecia parmelioid, scutelliform. Spermatogones with simple sterigmata or arthrosterigmata.

Genera: *Ecrinia*, Ach.; *Ecrinopsis*, Nyl.; *Parmelia*, Ach.; *Parmelopis*, Nyl.

Tribe 15. *Sticti*, Nyl.—Thallus large, lobate, cyphellate, or cyphellate beneath; gonidial stratum composed either of nodulose gonimia or of true gonidia. Apothecia lecanorine, rarely parmeliine. Spermatogones with arthrosterigmata.

Genera: *Stictia*, Nyl.; *Lobaria*, Nyl.; *Sticta*, Ach.; *Lobaria*, Nyl.; *Riccardia*, DN.

Tribe 16. *Peltigera*cei, Nyl.—Thallus frondosely dilated, the cortical stratum often wanting beneath; gonidial stratum consisting either of gonidia or (usually) of gonimia, rarely of gonidimia. Apothecia peltiform, adnate, or imbricate. Spermatogones (where seen) with arthrosterigmata.

Genera: *Nephroma*, Ach.; *Nephromium*, Nyl.; *Peltidea*, Ach.; *Peltigera*, Hoffm.; *Solarium*, Ach.

Tribe 17. *Physcia*cei, Nyl.—Thallus stellato-orbicular, rarely fruticulose, internally with woolly medulla; gonidial stratum consisting of true gonidia. Apothecia lecanorine. Spermatogones with arthrosterigmata.

Genus: *Physcia*, Nyl.

Tribe 18. *Parmeli*cei, Nyl.—Thallus stellato-lacinated, with woolly medulla and true gonidial stratum. Apothecia lecideine. Spermatogones with arthrosterigmata.

Genus: *Parmelia*, Fr.

Tribe 19. *Gyrophori*cei, Nyl.—Thallus umbilicately affixed, with woolly medulla and true gonidial stratum. Apothecia lecanoroid, or lecideine and gyrose. Spermatogones with arthrosterigmata.

Genera: *Umbilicaria*, Hoffm.; *Gyrophora*, Ach.

##### Series V.—*Phaceli*cei, Nyl.

Thallus variously crustaceous, sometimes evanescent, rarely hypophloeoid, without any filamentose medullary stratum. Apothecia lecanorine, or lecideine, or lielleiform.

Tribe 20. *Lecanora*cei, Nyl.—Thallus crustaceous, rarely evanescent or obsolete; gonidial stratum consisting of gonidia, rarely of gonimia. Apothecia lecanorine, rarely subbiatorine or typically biatorine. Spermatogones with simple sterigmata or arthrosterigmata.

Genera: *Pinnaria*, Del.; *Gammohymenia*, Nyl.; *Erioderma*, Fee; *Hypotrachyna*, Nag.; *Amphidoma*, Fr.; *Psoralea*, Fr.; *Lecanora*, Ach.; *Glyphispora*, Nyl.; *Peltula*, Nyl.; *Dermatiscum*, Nyl.; *Dicella*, Fr.

Tribe 21. *Peltisari*cei, Nyl.—Thallus crustaceous, continuous; gonidial system consisting of true gonidia. Apothecia endocarpioid or lecideoid. Spermatogones with simple sterigmata.

Genera: *Peltisaria*, DC.; *Parmularia*, Nyl.

Tribe 22. *Trematodromi*cei, Nyl.—Thallus crustaceous, or pulverulent, or obsolete, with true gonidial stratum. Apothecia uncinato-impressed with double margin. Spermatogones with simple or somewhat branched sterigmata.

Genera: *Phycia*, Wallr.; *Trematophyllum*, Nyl.; *Thelotrema*, Ach.; *Urocladia*, Ach.; *Palonia*, Krb.; *Gyrostomum*, Nyl.; *Ascidium*, Fee; *Gyrocampa*, Nyl.

Tribe 23. *Lecidei*cei, Nyl.—Thallus variously crustaceous, pulverulent, evanescent or none proper, with the gonidial stratum consisting of gonidia, rarely chrysogonidia, rarely gonimia. Apothecia lecideine or biatorine. Spermatogones with simple or simplish sterigmata.

Genera: *Caloglyphum*, Ehm.; *Byssocaulon*, Mnt.; *Parmularia*, Nyl.; *Cococarpus*, Pers.; *Lecidea*, Ach.; *Gyrodontium*, Nyl.; *Epiphora*, Nyl.

**Tribe 24. *Graphidei*, Nyl.**—Thallus thinly crustaceous, or hypophloeodal, or rarely none proper; gonidial stratum consisting of gonidia (rarely chrysogonidia). Apothecia lirelline or rotundate. Spermatogones with simple sterigmata.

Genera: *Xylographa*, Fr.; *Agyrium*, Fr.; *Lithographa*, Nyl.; *Graphis*, Ach.; *Thelographis*, Nyl.; *Helminthocarpon*, Fée; *Leucographa*, Nyl.; *Opegrapha*, Ach.; *Platygrapha*, Nyl.; *Stigmatidium*, Mey.; *Arthonia*, Ach.; *Melaspilca*, Nyl.; *Lecanactis*, Eschw.; *Schizographa*, Nyl.; *Glyphis*, Ach.; *Chiodecton*, Ach.

**Series VI.—*Pyrenocarpici*, Nyl.**

Thallus peltate, or crustaceous, or hypophloeodal, or evanescent. Apothecia nucleiform, with an apical ostiole.

**Tribe 25. *Pyrenocarpei*, Nyl.** Thallus various, often macular or obsolete; gonidial system consisting of gonidia (rarely chrysogonidia), sometimes of gonimia. Apothecia pyrenodeine, often without paraphyses. Spermatogones with simple sterigmata or arthrosterigmata.

Genera: *Cora*, Fr.; *Dichonema*, N. ab Es.; *Normandina*, Nyl.; *Endocarpon*, Hedw.; *Verrucaria*, Nyl.; *Verrucaria*, Pers.; *Thelocelia*, Nyl.; *Thelopsis*, Nyl.; *Obrizum*, Wallr.; *Strigula*, Fr.; *Paroethelium*, Nyl.; *Melanotheca*, Fée; *Trypethelium*, Ach.; *Astrothelium*, Eschw.

**Series VII.—*Peridioidi*, Nyl.**

Thallus thin, often wanting. Apothecia peridicene, without any ostiole.

**Tribe 26. *Peridii*, Nyl.**—Thallus thin, macular, or none proper. Apothecia consisting of a peridium. Spermatogones (when seen) with simple sterigmata.

Genera: *Thelocarpon*, Nyl.; *Thelococcus*, Nyl. *Endococcus*, Nyl.; *Mycoporium*, Flot.

**Family IV.—*Myriangiacei*, Nyl.**

Thallus unstratified, entirely and equally cellular. Fruetification not discrete.

**Tribe 1. *Myriangeli*, Nyl.**—Thallus noduloso-pulvinate. Apothecia subcanorine. Spermatogones unknown.

Genus: *Myriangium*, Nutt. and Berk.

In the *Nyländeren* arrangement, most of these tribes and genera are divided into subtribes and subgenera, the latter being further subdivided sections according to the affinities of the different species.

**Habitats and Distribution of Lichens.**

These two subjects are intimately related and present many interesting features which here we can only very generally notice without entering into details.

1. **Habitats of Lichens.**—These are extremely varied, and comprehend a great number of very different substrata. Chiefly, however, they are the bark of trees, rocks, the ground, mosses, and, rarely, perennial leaves. (a) With respect to *corticole* lichens, some prefer the rugged bark of old trees (e.g., *Ramalina*, *Parmelia*, *Stictis*) and others the smooth bark of young trees and shrubs (e.g., *Graphidei* and some *Lecideæ*). Many are found principally in large forests (e.g., *Usnea*, *Alcornoque*); while a few occur more especially on trees by roadsides (e.g., *Physcia parietina* and *Ph. pulcherrima*). In connexion with corticole lichens may be mentioned those *lignicole* species which grow on decayed or decaying wood of trees and on old pales (e.g., *Colicis*, various *Lecideæ*, *Xylographa*). (b) As to *saxicole* lichens, which occur on rocks and stones, they may be divided into two sections, viz., *calcicole* and *calci-fugous*. To the former belong such as are found on calcareous and cretaceous rocks, and the mortar of walls (e.g., *Lecanora calcarea*, *Lecidea calcivora*, and several *Verrucaria*), while all other saxicole lichens may be regarded as belonging to the latter, whatever may be the mineralogical character of the substratum. It is worthy of notice that the apothecia of several calcicole lichens (e.g., *Lecanora Præstii*, *Lecidea calcivora*) have the power (through the carbonic acid received from the atmosphere) of forming minute favcoli in the rock, in which they are partially buried. (c) With respect to *terricole* species, some prefer peaty soil (e.g., *Cladonia*, *Lecidea decolorans*), others calcareous soil (e.g., *Lecanora crassa*, *Lecidea decipiens*), others argillaceous soil or hardened mud (e.g., *Collema limosum*, *Peltidea venosa*); while many may be found growing on all kinds of soil,

from the sands of the sea-shore to the granitic detritus of lofty mountains, with the exception of course of cultivated ground, there being no agrarian lichens. (d) *Muscirole* lichens again are such as are most frequently met with on decayed mosses and jungermannias, whether on the ground, trees, or rocks (e.g., *Leptogium muscirole*, *Gomphillus calicioides*). (e) The *epiphyllous* species are very peculiar as occurring upon perennial leaves of certain trees and shrubs, whose vitality is not at all affected by their presence as it is by that of fungi. In so far, however, as is known, they are very limited in number (e.g., *Lecidea Bouteillei*, *Strigula*). With the exceptions of these last, it is to be observed that all the rest may, under different conditions of locality and climate, be found growing for the most part indiscriminately on the substrata mentioned, a normally saxicole species becoming corticole, a terricole one becoming muscirole, and *vice versa*. Amongst other instances of this that might be adduced, the case of *Lecidea geographica*, a peculiarly saxicole species, growing on the stems of *Rhododendron* in the Tyrolean Alps, and that of *Lecidea rivulosa*, a like peculiarly saxicole species, growing on the bark of trees in Germany, are especially striking. Sometimes also various lichens occur abnormally in such unexpected habitats as dried dung of sheep, bleached bones of reindeer and whales, old leather, iron, and glass, in districts where the species are abundant. Consequently it is apparent that in many cases lichens are quite indifferent to the substrata on which they occur, whence we infer that the preference of several for certain substrata depends upon the temperature of the locality or that of the special habitat. Thus in the case of saxicole lichens the mineralogical character of the rock has of itself little or no influence upon lichen growth, which is influenced more especially and directly by their physical properties, such as their aptitude for imbibing and retaining heat and moisture. As a rule lichens have a propensity for open exposed habitats, though some are found only or chiefly in shady situations; while, as already observed, scarcely any occur where the atmosphere is impregnated with smoke. Many species also prefer growing in moist places by streams, lakes, and the sea, though very few are normally, and probably none entirely, *aquatic*, being always at certain seasons exposed for a longer or shorter period to the atmosphere (e.g., *Lichina*, *Leptogium rivulare*, *Endocarpon fluriale*, *Verrucaria naura*). Some species are entirely parasitical on other lichens (e.g., various *Lecideæ* and *Pyrenocarpei*), and may be peculiar to one (e.g., *Lecidea vitellinaria*) or common to several species (e.g., *Habrothallus parmeliarum*). A few, generally known as *erratic* species, have been met with growing unattached to any substratum (e.g., *Parmelia revoluta*, var. *concentrica*, *Lecanora esculenta*); but it seems somewhat doubtful if these are really free *ab initio* (vide Crombie in *Journ. Bot.*, 1872, p. 306). It is to the different characters of the stations they occupy with respect to exposure, moisture, &c., that the variability observed in many types of lichens is to be attributed. The fact also that in numerous instances they are so indifferent to the nature of their habitats clearly shows that they do not at all depend upon the substratum for their nourishment.

2. **Distribution of Lichens.**—From what has now been said it will readily be inferred that the distribution of lichens over the surface of the globe is regulated, not only by the presence of suitable substrata, but also and more especially by atmospherical and climatal conditions. At the same time it may safely be assumed that their geographical range is more extended than that of any other class of plants, occurring as they do in the coldest and warmest regions—on the dreary shores of the palæocretic sea and in the torrid valleys of tropical climates, as well as on

the greatest mountain elevations yet attained by man, on projecting rocks even far above the snow-line (e.g., *Lecidea vancouverica*), where, as in many other situations, fungus-nycelium and gonidoid algal are unknown. Our knowledge of the distribution of lichens in various countries, like that of other plants, is derived from general and local sources, from special works on lichenology, from the observations of scientific travellers and the collections made by them in distant parts of the world. Most of these, however, of an earlier date, are to be used with great caution, as the species recorded were, in the absence of microscopical examination, not sufficiently discriminated, and in many cases are *prima facie* entirely erroneous. Amongst botanical travellers whose contributions are most trustworthy may be mentioned pre-eminently Sir Joseph D. Hooker, whose remarks on this subject in his *Flora Antarctica* and in various papers in *Trans. Linn. Soc.*, vol. iv., &c., are most valuable and suggestive. Again, in purely lichenological works, the general principles regulating lichen distribution (with statistical tables) are admirably expounded by Nylander in the introduction to his *Synopsis Methodica Lichenum*, while the only complete record of the distribution of species is that given by the same author in his *Énumération générale des Lichens*. Since the date of his latter work (1858) our knowledge of the range of lichens, both European and exotic, has been greatly extended, apart from the discovery of numerous species previously unknown. No special treatise, however, on the subject has been published, though there is now ample material, very much scattered no doubt, available for the purpose. It may, however, be observed that of the four thousand species (exclusive of numerous varieties and forms) which have been described, the geographical distribution is known almost as well as that of phanerogams and siliques, as well, if not more so than that of mosses and hepatics, and far better than that of algae and fungi. In arctic regions lichens form by far the largest portion of the vegetation, occurring everywhere on the ground and on rocks, and fringing freely; while terricole species of *Cladonia* and *Stereocaulon* are seen in the greatest luxuriance and abundance spreading over extensive tracts almost to the entire exclusion of other vegetation. The lichen flora of temperate regions is essentially distinguished from the preceding by the frequency of corticole species belonging to *Lecanora*, *Lecidea*, and *Graphidii*. In inter-tropical regions lichens attain their maximum development (and beauty) in the foliaceous *Stictis* and *Parmelias*, while they are especially characterized by epiphyllous species, as *Utricularia*, and by many peculiar corticole *Thelotrema*, *Gyalis*, and *Pyrenocarpi*. Some lichens, especially saxicole ones, seem to be cosmopolitan (e.g., *Lecanora subfusa*, *Cladonia pyxidata*); and others, not strictly cosmopolitan, have been observed in regions widely apart. A considerable number of species, European and exotic, seem to be endemic, but further research will no doubt show that most of them occur in other climatal regions similar to those in which they have hitherto alone been detected. To give any detailed account, however, of the distribution of the different genera (not to speak of that of individual species) of lichens would necessarily far exceed the limits at our disposal. Suffice it to say that both in horizontal and vertical range, they sufficiently correspond with the distribution of phanerogams in the several regions of vegetation into which the surface of the globe has been divided. The proportion of lichens to phanerogams in different regions increases in a regular ratio from the equator to the poles, and from the base to the summit of lofty mountains, till at length in more arctic and alt-alpine tracts lichens constitute almost and sometimes entirely the sole vegetation.

(J. M. C.)

LICHFIELD, a city and municipal and parliamentary borough of Staffordshire, England, is situated in a pleasant and fertile valley, on a small tributary of the Trent, and on the South Staffordshire Railway, 16 miles north from Birmingham. The town is well built, and contains many handsome houses. Of the old Norman cathedral there are now no remains. The present building is supposed to belong to the end of the 12th or beginning of the 13th century. Its style is Early English approaching to Decorated, and it possesses an imposing central tower 285 feet in height, with two western spires 183 feet. The transepts, which contain some portions of Norman architecture, are richly ornamented, and adorned with windows of beautiful tracery. The total length of the building from east to west is 403 feet. The damage which it suffered during the civil wars was repaired by Bishop Hackett in 1671, and at present (1882) it is undergoing extensive restorations. A new building for the King Edward's grammar school was erected in 1850. In the market place is a statue of Dr Johnson, facing the house where he was born. A guild-hall, a market-hall, a coin exchange, and a public library and museum are the principal buildings of a secular character. There are several charitable institutions. The industries of the town include brewing and coach building; and in the neighbourhood there are large nurseries and market gardens. The municipal and parliamentary boroughs have the same area (3416 acres); the population in 1871 was 7347, and in 1881 8360.

Lichfield is spelt by Bode Lichelli, the word being supposed to mean 'Field of the Dead,' from a mass grave which took place near it of a large number of Christians. It was made an episcopal see in 692, St Chad being its first bishop. In the reign of Offa it was promoted to be an archbishopric, but in 853 the primacy was restored to Canterbury. In 1075 the see of Lichfield was transferred to Chester, and thence, a few years afterwards, to Coventry, but it was restored in 1118. The town has returned members to parliament since 1305, at which time it also received a charter of incorporation. Since 1867 it has returned only one member. It was made a city by Edward VI. in 1549.

See the history of Lichfield by Jackson (1765) and Howard (1768), and histories of the cathedral by Patton (1820) and Stone (1879).

LICHTENBERG, formerly a small German principality on the west bank of the Rhine, enclosed by the Nahe, the Blies, and the Glan, now forms the Circle of St Wendel in the government district of Treves, Rhenish Prussia. The principality was constructed of parts of the old electorate of Treves, Pfalz Zweibrücken, and Salm, and lay between Rhenish Bavaria and the old Prussian province of the Rhine. Originally called the lordship of Baumböcker, it owed the name of Lichtenberg and its elevation to a principality to Ernest, duke of Saxe-Coburg, to whom it was presented by Prussia in 1815 in accordance with terms agreed upon at the congress of Vienna. The duke, however, restored it to Prussia in 1834, in return for an annual pension of £26,000 sterling. The area is 210 square miles, and the population 45,000.

LICHTENBERG, GEORG CHRISTOPH (1744-1799), physicist and satirical writer, was born at Oberramstadt, near Darmstadt, July 1, 1744. In 1763 he entered Göttingen university, where in 1770, after spending several years in England, he became extraordinary professor of physics, and five years later ordinary professor. This post he continued to hold till his death, February 24, 1799. As a physicist he is best known for his investigations in electricity, more especially as to the so-called Lichtenberg figures (see vol. viii. p. 66), which are fully described in two memoirs: *De nova methodo utrumque ac motum electricitatis investigandi* (Göttingen, 1778-79). He sent many excellent contributions to the Göttingen *Taschenkalender* from 1778 onwards, and to the *Göttingische Magasin der Literatur und Wissenschaft*, which he edited for three years (1780-82) along with J. G. A. Forster.

His various scientific writings occupy the latter part of his *Vermischte Schriften*, edited by Kriess (9 vols., Göttingen, 1800-5; new edition, 6 vols., Gotha, 1844-46). The earlier volumes of these collected writings contain his satirical and humorous productions. His keen satire involved him in many a literary controversy with well-known contemporaries, such as Lavater, whose science of physiognomy he wittily ridiculed, and Voss, whose views on Greek pronunciation called forth a powerful satire *Ueber die Pronunciation der Schöpsse des alten Griechenlandes* (1782). Notes of his lectures on natural philosophy, astronomy, and physical geography were published by Gamauf (Vienna, 1808-12, 1813, 1819); and more recently some of his brilliant sayings have been collected by Grisebach in one volume, *Lichtenberg's Gedanken und Maximen: Licht-Strahlen aus seinen Werken* (Leipsic, 1871).

LICINIUS. Publius Flavius Galerius Valerius Licinianus Licinius, Roman emperor, of Dacian peasant origin, was born probably about 250 A.D., and was elevated after the death of Severus to the rank of Augustus by Galerius, his former friend and companion in arms, on November 11, 307, receiving as his immediate command the provinces of Illyricum. On the death of Galerius in May 311, he shared the entire empire with Maximin, the Hellespont and the Thracian Bosphorus being their mutual boundary. In March 313 he entered into alliance with Constantine at Milan, and in the following month inflicted a decisive defeat on Maximin at Heraclea, with the result of establishing himself as master of the East, while Constantine (now his brother-in-law) was supreme in the West. In the following year his jealousy led him to encourage a treasonable enterprise on the part of Bassianus against Constantine. When his perfidy became known a civil war ensued, in which he was twice severely defeated—first near Cibalis in Pannonia (October 8, 314), and next in the plain of Mardia in Thrace; the outward reconciliation, which was effected in the following December, left Licinius in possession of Thrace, Asia Minor, Syria, and Egypt, but added numerous provinces to the Western empire. In 323 Constantine, tempted by the "advanced age and unpopular vices" of his colleague, anew declared war against him, and, having defeated his army at Adrianople (July 3, 323), succeeded in shutting him up within the walls of Byzantium. The defeat of the superior fleet of Licinius by Crispus, Constantine's eldest son, compelled his withdrawal to Bithynia, where a last stand was made; the battle of Chrysopolis (September 18) finally issued in his submission and death.

LIEBER, FRANCIS (1800-1872), a distinguished publicist and writer on political science, was by birth a German, by adoption a citizen of the United States. He was the son of Frederick William Lieber, and was born at Berlin, March 18, 1800. Upon the return of Napoleon Bonaparte from Elba, young Lieber, then only fifteen years of age, volunteered as a soldier, and served with his two brothers under Marshal Blücher in the campaign of 1815. He fought at Ligny, Waterloo, and Namur. In the last-named battle he was twice severely and dangerously wounded. At the close of the war he returned to his studies, and joined the Berlin gymnasium under Dr Jahn. Shortly afterwards he was arrested and thrown into prison for his political sentiments, the chief evidence against him being several songs of liberty which he had written. After several months' confinement he was discharged without a trial, but informed that he would not be permitted to pursue his studies at the Prussian universities. He accordingly went to Jena, where he took his degrees in 1820, subsequently continuing his studies at Halle and Dresden. When the Greek revolution broke out, young Lieber instantly resolved to take part in the struggle for

Græcian independence. He made his way with great difficulty to Marseilles, travelling much of the way on foot, and thence embarked for Greece. His experiences there are recorded in his *Journal in Greece*, published at Leipsic in 1823, and at Amsterdam in the same year under the title of *The German Anacharsis*. Returning from Greece after the failure of the struggle, he landed at Ancona, and proceeded to Rome. There he made the acquaintance of Niebuhr, then Prussian ambassador to Rome, who took great interest in him and employed him as tutor to his son. He lived a year in the family of the historian, a period of his history which he afterwards embalmed in his *Reminiscences of Niebuhr*, first published in America, and afterwards in England. Returning from Rome to Berlin in 1823, he was soon again arrested by the Prussian authorities on the old charges of enmity to the Government and advocating republican opinions, and was imprisoned in the bastille of Koepnik, but was released after some months' confinement through the influence of Niebuhr. In 1825 he abandoned his country, and after spending a year in London went to the United States (1827), and as soon as possible was naturalized as a citizen of that country. Lieber took up his residence at Boston, and was occupied for five years in his laborious work *The Encyclopedia Americana* (13 vols.). In 1832 he removed to New York, where he published a translation of De Beaumont and De Tocqueville's work on the penitentiary system, with many notes. In 1833 he went to Philadelphia to prepare a plan of education for Girard College, then newly founded. While there he published *Letters to a Gentleman in Germany* and a supplement to his *Encyclopedia*. In 1835 he was appointed professor of history and political economy in South Carolina College at Columbia, S.C., where he remained more than twenty years, and during this period wrote and published the three great works upon which his fame as a writer chiefly rests—the *Manual of Political Ethics* (1838), *Legal and Political Hermeneutics* (1839), and *Civil Liberty and Self Government* (1853).<sup>1</sup>

In 1856 Lieber resigned the professorship in South Carolina College, and was immediately elected to a similar professorship in Columbia College, New York, and to the chair of political science in the law school of the same institution. He continued in the discharge of the duties of these positions until his death, which occurred October 2, 1872. During the great war for the preservation of the Union from 1861 to 1865, Lieber rendered services of great value to the Government of his adopted country, and was frequently consulted by the secretary of war. He was one of the first to point out by his pen the madness of secession, and was ever active in supporting the Government and upholding the Union. He prepared, upon the requisition of the president, the *Code of War for the Government of the Armies of the United States in the Field*, which was adopted and promulgated by the Government in General Orders No. 100 of the war department. This code has been characterized by many European publicists as a masterpiece, and it suggested to Bluntschli his codification of the law of nations, as may be seen in the preface to his *Droit International Codifié*. During this period also Lieber wrote his *Guerilla Parties with Reference to the Laws and Usages of War*, a valuable contribution to the law of war. At the time of his death he was by appointment of the Government of the United States the umpire of the commission for the adjudication of Mexican claims. The political writings of Francis Lieber are held in great estimation by all publicists. Sir Edward S.

<sup>1</sup> New editions of these works and of his miscellaneous writings have been published recently at Philadelphia.

Creasy, in his *First Platform of International Law*, alluding to his death, has justly said of him, "America and the civilized world in general have lately had to deplore in his death the loss of one whom the French jurist M. Laboulaye has truly styled 'une des figures les plus originales parmi les jurisconsultes de notre temps.'"

Besides the works already mentioned, Lieber published at various times many smaller works and pamphlets on different subjects, all of which attracted public attention, such as *The Origin and Development of the First Constituents of Civilization*, *Great Events Described by Great Historians*, *Essays on Property and Labour*, *The Laws of Property*, *Penal Laws and the Penitentiary System*, *Prison Discipline*, *The Relation between Education and Crime*, *The Pardoning Power*, *The Character of the Gentleman*, *International Copyright*, *Laura Bridgman's Vocal Sounds*, *On Anglican and Gallican Liberty*, *The Post Office and Postal Reforms*, *Independence of the Judiciary*, *Nationalism*, *Rise of the Constitution* (an unfinished work), and many minor tracts and publications. These works are all written with as much ease and purity of idiom as if English had been his native tongue, a fact not more remarkable than that he, a German, should have become the great American teacher of the philosophy of Anglican political science. (M. R. T.)

LIEBIG, JUSTUS (1803–1873), was born at Darmstadt in 1803. His father carried on business as a drysalter and dealer in dye-stuffs, and made various experiments with a view to improved methods of preparing and purifying his wares. These led the son to take an interest in chemistry, and to seek for knowledge in the chemical books and periodicals in the grand-ducal library, which is rich in scientific works. At home he employed his time in repeating, as far as the means at his command admitted, the experiments he found described in books, and thus while still a boy attained a theoretical and practical knowledge of chemistry comparable with that of many full-grown professors of the science. He determined to be a chemist, to devote his life to the pursuit of science. The only kind of chemist available for teaching purposes was the chemist and druggist, and accordingly Liebig, at the age of fifteen, entered the shop of an apothecary at Heppenheim near Darmstadt to study chemistry. He soon found out how great is the difference between practical pharmacy and scientific chemistry, and returned to Darmstadt, after ten months, to look for another and more likely way of attaining his object. After some months spent in study at home he entered the university of Bonn, which he soon left for Erlangen. There he attended the lectures of Kastner on chemistry, and, besides the study of allied sciences, devoted some time to make up for the almost total neglect of school work caused by his early love of chemistry. He was much influenced by the metaphysical speculations of Schelling, and in after life referred to this influence as injurious to him as a scientific investigator. In those days there were no laboratories accessible to ordinary students, and Liebig had to content himself with what the university could give him in the lecture-room and in the library. Both at Bonn and at Erlangen he formed a students' chemical and physical society for the discussion of new discoveries and speculations as these appeared in scientific books or periodicals. In 1822 he left Erlangen with the degree of Ph.D. By means of the liberality of Louis I., grand-duke of Hesse Darmstadt, Liebig was enabled to continue his chemical studies in Paris. There he made the acquaintance of Runge, Mitscherlich, and Gustav Rose. He attended the lectures of Gay-Lussac, Thenard, and Dulong, and, while carrying on the investigation into the composition and properties of the fulminates which he had already partly published, he attempted, as at Erlangen, to work up his neglected school studies. The results of his work on the fulminates were communicated to the Academy of Sciences, and attracted the favourable attention of Humboldt, who was at that time in Paris. Humboldt introduced Liebig to Gay-Lussac, who admitted him into his private laboratory as a pupil. Here he had opportunities of learning all the mysteries of the art from

one of the most skilful and ingenious of experimenters. It was on the advice of Humboldt that Liebig determined to become a teacher of chemistry, but difficulties stood in his way. As a native of Hesse-Darmstadt, he ought, according to the academical rules of the time, to have studied and graduated at the university of Giessen, and Humboldt had to use his influence to induce the authorities to forgive his having attended the foreign university of Erlangen. After examination his Erlangen degree was recognized, and in 1824, in his twenty-first year, he was appointed extraordinary professor of chemistry in the university of Giessen. Two years later he was promoted to the post of ordinary professor, which he held for twenty-five years, notwithstanding the most tempting offers from other universities. It was here, in the small town and small university of Giessen, that by far the most of Liebig's work was done. He began by remedying the evil which as a student he had himself felt. He induced the Darmstadt Government to build a chemical laboratory in which any student of the university might obtain a thorough practical training. It is difficult for us, who live in a time when nearly every university and many schools possess well-arranged and often well-endowed laboratories, to understand how great a revolution was made in the practical teaching of physical science by the foundation of the Giessen laboratory. We can form some idea of it by reading Liebig's articles on the condition of chemistry in Austria and Prussia, in which he goes over in detail the means of teaching afforded in the various universities of those great countries. He tells us that in 1838 two young Prussians came to Giessen to study chemistry, unable to obtain entrance to a laboratory in their own country, but were ordered back again by the Prussian Government. Fortunately other Governments were less strict, or other students were less obedient, and crowds of young men anxious to study chemistry came to Giessen, and carried home the light there acquired. Partly by Liebig's urgent appeals to the interests and to the shame of the great German states, partly by the influence of his pupils, a great reform was effected, and German universities now vie with one another in offering opportunities of practical instruction in chemistry and the other physical sciences.

The amount and the importance of the laboratory work done by Liebig in Giessen were very great. Without considering here the work done by his students under his direction, of which no doubt a very large part was conceived by him, and in the execution of which he constantly contributed his assistance and advice, we shall look only at what appears under his own name. During the twenty-six years he spent at Giessen as ordinary professor, he contributed to scientific journals more than two hundred papers, about twenty of which were records of joint work, chiefly with Wohler. During the same time he published his works on organic analysis, organic chemistry, chemistry applied to physiology and agriculture, his *Chemical Letters*, and many smaller treatises. From 1832 he was joint editor of the *Annalen der Pharmacie*, from 1837 of the *Handwörterbuch der reinen und angewandten Chemie*, and from 1847 to 1856 of the *Jahresbericht der Chemie*. These statements give some idea of the amount of his work; of its importance and of its effect on the history of science we shall speak later.

In 1815 he was raised to the hereditary rank of baron under the title of Freiherr von Liebig. In 1852 he accepted the invitation of the Bavarian Government to the ordinary professorship of chemistry in the university of Munich. This office he held till his death in 1873.

In private life Liebig was hospitable, courteous, and kindly. Honoured by all the great scientific societies of the world, and regarded by almost every one as the great authority in chemistry, he assumed no airs of superiority,

and lived the simple and quiet life of a German professor. Liebig's influence on the history of chemistry may be considered under five heads:—(1) the effect of the opening of the Giessen laboratory, and of Liebig's constant efforts to induce other universities to follow this example; (2) the improvements introduced by him in methods of investigation and in apparatus; (3) the discovery of new facts; (4) the development of theory; and (5) the application of chemistry to physiology, agriculture, and the arts.

We have already spoken of the first. Under the second head by far the most important change introduced by Liebig was his method of organic analysis. Organic substances were analysed, and analysed with accuracy, before 1830, but such analyses could then be carried out only by highly skilled chemists, and involved great labour and the use of cumbersome apparatus. Liebig's method of organic analysis, which was published in all its details in 1831, and which (with important but secondary improvements) is that still used, made it easy for any advanced student to make a fairly accurate and very useful analysis of an organic substance. Analysis is to the chemist what astronomical methods for determining longitudes and latitudes are to the geographical explorer. Without it many interesting and useful discoveries may be made, but it is only when complete and accurate analyses are made of all the new substances produced in the course of a research that the research becomes fully available to other explorers. If Liebig had contributed nothing to organic chemistry but his method of analysis, he would still have been in a perfectly true sense the founder of modern organic chemistry. Many other improvements of apparatus are due to him; we need only mention the simple form of condenser called by his name, and constantly used by every chemist, and the easy and accurate method for determining the quantity of urea in a solution, which was the first step towards introducing precise chemical methods into practical medicine. This is also the proper place to refer to his analyses of the natural alkalis, and his discovery of the method of determining their equivalents by the analysis of their chloroplatinates. In the third place we have to consider the new facts discovered by Liebig. The very great addition to our knowledge of organic chemistry made by Liebig naturally throws into the shade his contributions to inorganic chemistry, but we ought to remember his numerous analyses of mineral waters and his contributions to the difficult question of the accurate separation of cobalt and nickel. It is, however, in organic chemistry that Liebig's great discoveries were made. These discoveries are so intimately connected with his chemical theories that we may most conveniently consider them along with the fourth head, his contributions to the development of chemical theory.

The notion of compound radicals is to be found in chemistry as far back at least as the time of Lavoisier. Lavoisier says, "Some experiments of my own and some made by M. Hassenfratz have convinced me that in general nearly all the vegetable acids, such as tartaric, oxalic, citric, malic, acetic, pyrotartaric, pyromucic acids, have for their radical hydrogen and carbon, but united so as to form a single base, that all these acids differ from one another by the difference in proportion of the two substances and the degrees of oxidation." Berzelius adopted this view and expressed it thus:—"We find the difference between organic and inorganic bodies to be that, while in inorganic nature all the oxidized substances have a single radical, all the organic substances have compound radicals. Just as ammonia is an alkali with a compound radical, but possessing nevertheless the greatest analogies with the mineral alkalis which have simple radicals, so we find the greatest analogy between the mineral and the organic acids, so that the relations of potash and soda to tartaric, oxalic, citric acids are the same as their relations to sulphuric, nitric, phosphoric acids." These views were published by Berzelius in 1817. In 1815 Gay-Lussac had discovered cyanogen, and shown that this compound of carbon and nitrogen is the radical of prussic acid and its salts, in the same sense as chlorine is the radical of hydrochloric acid and the chlorides. Aspre had in 1814 laid the basis of the constitution of the ammoniacal salts, which Berzelius worked out in detail, according to which these salts contain a compound radical, ammonium, playing in them the part of potash in the potash salts. Finally, Davy suggested in 1815 that the hydrated acids which correspond in function to hydrochloric acid should be regarded as the true acids, and proposed to represent the other compounds of hydrogen with a radical.

Such were the knowledge and the theoretical position of chemists on this question when Liebig became professor; the dates to which we have referred correspond to the time when as a schoolboy he was devouring the contents of chemical journals at Darmstadt, and no doubt he then became acquainted at first hand with the discoveries and speculations of Ampère, Davy, Gay-Lussac, and Berzelius.

We have seen that his first investigation referred to the fulminates. He continued his researches upon the compounds of cyanogen and the substances connected with them formed frequent

subjects of his researches during his whole life. In this region of organic chemistry he made many important discoveries, of which the limits of this article do not allow a detailed account; we can only mention melone, mellam, ammeline, ammelide, and melanine, as substances discovered and investigated by him. In the course of these investigations he discovered the precise nature of the chemical changes which occur in the manufacture of bromide of potash. In 1831 he examined the action of chlorine upon alcohol, among other substances discovered chloral, and commenced the series of investigations into the derivatives of alcohol and ether to which we shall refer immediately. In 1832 Wöhler and Liebig published the results of their joint research on the oil of bitter almonds and its derivatives. This research may be said to stand at the head of modern organic chemistry. For elegance of method and for clearness of insight it is unrivalled, and will always remain a model of what such an investigation should be. They showed in the clearest manner that the compound  $C_7H_6O$  (here and elsewhere in this article we use the symbols now in common use, instead of those employed by the authors), to which they gave the name of benzoyl, is the constant part, or radical, of a great series of compounds. The importance of this investigation was generally recognized. Berzelius hailed it as the advent of real daylight on the subject of organic chemistry, and even suggested the names pruin or othrin (from *pruin* and *ἔσθρος*) for the newly discovered radical.

We now come to the long controversy as to the constitution of alcohol and ether, which engaged so much of Liebig's time and energy. Gay-Lussac had shown in 1815 that alcohol and ether might, as far as their composition is concerned, be represented as compounds of olefiant gas and water, and further that, if we represent the quantities by volume of gas or vapour, ether contains one volume of olefiant gas and half a volume of water vapour, while alcohol contains equal volumes of the two. In 1828 Dumas and Boullay published an elaborate memoir on the preparations and properties of the ethers, in which they further developed the ideas suggested by Gay-Lussac. They regarded olefiant gas as the radical of all the ethereal compounds, as ammonia is of the ammoniacal salts, and formulated them thus:—

	Base.	Acid.	Water.
Sal ammoniac .....	$NH_3$	$HCl$	...
Muriatic ether .....	$C_2H_4$	$HCl$	...
Sulphate of ammonia .....	$2NH_3$	$N_2O_5$	$H_2O$
Sulphous ether .....	$2C_2H_4$	$N_2O_3$	$H_2O$
Ether .....	$2C_2H_4$	...	$H_2O$
Alcohol .....	$C_2H_4$	...	$H_2O$
Ammoniacal solution .....	$NH_3$	...	$2H_2O$

We have given only a sample of their tables, leaving out among others some substances in reference to the composition of which they had fallen into error, error which Liebig detected and used as an argument, valid enough then no doubt, but of little interest now.

In 1834 Liebig proposed a quite different theory, one which stands to Dumas and Boullay's in the same relation which the ammonium theory holds to the ammonia theory of the constitution of the ammoniacal salts. Just as Ammonium Berzelius regarded sal ammoniac, not as  $NH_3.HCl$ , but as  $NH_4.Cl$ , so Liebig proposed for muriatic ether the formula  $C_2H_5.Cl$  instead of  $C_2H_4.HCl$ . The really cogent argument which he brought forward, the argument which we can now best appreciate, is that, while alcohol contains combined water, ether does not. According to Dumas and Boullay alcohol and ether are both hydrates, but in Liebig's view ether is  $(C_2H_5)_2O$  and alcohol  $(C_2H_5)_2O.H_2O$ . If we wish to understand this argument we must recollect that to the chemists of that time oxidized hydrogen was water, and Liebig's arguments are as sound now as they were then, for the most recent views represent alcohol as  $C_2H_5.O-H$ , and this contains oxidized hydrogen, or, as we may say, half a molecule of water, and Liebig's tests do not distinguish preformed water, but hydrogen and oxygen combined as they are in water. Much debate and investigation followed, in the course of which the relations of all the substances derived from alcohol were thoroughly and practically studied in a fuller and more careful manner than would have been possible had there not been a theoretical point to defend and to attack. The enormous number of facts discovered by Liebig put him in a very favourable position as the advocate of his theory. Chemists could not do without a knowledge of these facts, and they could only get this knowledge through Liebig's papers, in which the facts were expressed in the language of his theory.

In 1835 Regnault began a series of most important researches into the compounds derived from olefiant gas. He showed that many of these substances might be classified and their relations explained by the assumption of a radical  $C_2H_3$ , to which he gave the name of aldehydene. Liebig saw that according to his view of the meaning of the word radical, as "the unchanging constituent in a series of compounds," the same radical may be assumed in alcohol and in acetic acid, and in 1839, in a note published in the *Annalen*, he puts the matter in a very clear light. He says, "Ether and ammonia have in their a certain resemblance which was

first indicated by Dumas and Boullay, and the view of the constitution of the ammonia salts which is generally held in France was the reason why ether was considered the first hydrate of olefiant gas, alcohol as the second hydrate, &c.; in Germany and other countries the water necessary for the constitution of the salts of ammonia with oxygen acids was considered as an integral part of the base; it was assumed that this water forms with the ammonia oxide of ammonium ( $\text{NH}_4$ )<sub>2</sub>O, and this view in a certain sense smoothed the way for another, according to which the existence of organic oxides, capable of neutralizing acids, appeared very probable, as a necessary complement to the organic acids which chemists had long been inclined to regard as oxides of organic radicals. Ether was in these countries regarded as an organic oxide, and this difference of view excited a ten years' strife, as an immediate result of which we may regard the discovery of a great number of compounds which enriched science with innumerable important observations. No region of organic chemistry has been so thoroughly and so completely studied as the compounds connected with ether; and now, when the existence of organic oxides is no longer denied, the support of the opposite opinion has come to an end, although it cannot be said that the question itself has been experimentally decided. If we compare in the light of our present knowledge the ammonia compounds with the ether compounds we at once see that the opposing views were fundamentally the same in the two cases. The disputes took place because we were not one as to the interpretation of the phenomena. The ether and ammonia compounds assume in fact the same form if amidogen is regarded as the unchangeable radical of the ammonia compounds, and acetyl [Regnault's aldehyde] as the starting point of the ether compounds. The two sets of compounds differ only in so far as we must ascribe to acetyl the power of forming acids, a power which amidogen does not possess.

He then gives a table containing in two columns the ammonia and the ether compounds, in which  $\text{C}_2\text{H}_5$  corresponds to  $\text{NH}_2$ ,  $\text{C}_2\text{H}_4$  to  $\text{NH}$ , and  $\text{C}_2\text{H}_3$  to  $\text{NH}$ , and adds, "These formulæ require no explanation; they have been developed in order to show the extraordinary resemblance of the ammonia and the ether compounds, and to show why it was that many chemists regarded olefiant gas as the first member of the series of ether compounds. Both of the formerly antagonistic theories have, as may be easily seen, from this point of view the same foundation, and all further questions as to the truth of the one or other view is thus of course set at rest."

It was during the course of the controversy which then closed that Liebig had discovered aldehyde, chloral, and, simultaneously with Soubeiran, chloroform, besides numerous other substances of less general interest, and developed the theory now generally received of the formation of ether by the action of sulphuric acid on alcohol.

In the very short sketch given above of the discussion as to the constitution of ether, we mentioned that Liebig's ethyl theory was to some extent borrowed from Berzelius. Berzelius had suggested that ether was the oxide of a radical (Liebig's ethyl), but he was at first inclined to regard alcohol, not as the hydrate oxide of the same radical, but rather as the oxide of another one, which with our symbols would be written  $\text{C}_2\text{H}_5$ . But there was a deeper difference than this between the radical theories of Berzelius and Liebig. This essential difference first clearly showed itself in the notes which Liebig added to two letters from Berzelius to Wohler, published in the *Annalen* in 1839. In these letters Berzelius gives his views of the constitution of oxychlorides, with which he classes such bodies as trichloroacetic acid. All these bodies he represents as compounds of oxides and chlorides, in harmony with the dualistic system.

Thus, instead of  $\text{SO}_2\text{Cl}_2$ ,  $\text{C}_2\text{HCl}_3\text{O}_2$ , &c., he writes  $\text{SOCl}_2 + 2\text{SO}_2$ ,  $\text{Cl}_2 + \text{C}_2\text{O}_2$ , &c. (taking the anhydrous acid). In his second letter on Malaguti's chlorinated ethers he naturally arrives at formulæ of extreme complexity. In his notes Liebig states that he does not agree with Berzelius, and that the analogy first pointed out by Berzelius between inorganic and organic compounds and his theory of organic radicals had been a guiding star in a labyrinth in which previously no one could find the way. "But, while there are points of resemblance, there are very many points of difference; we should follow a theory as long as it gives us light and explains facts; up to a certain point the principles of inorganic chemistry help us in organic chemistry, beyond it they leave us, and produce instead of removing complications; beyond this point we require new principles."

These new principles were supplied by Liebig's radical theory. As Liebig showed, abstract discussions as to the truth of a theory are out of place in an experimental science; the question is not as to their essential truth but as to their practical fruitfulness. Do they help us to understand old and to discover new facts? If they do, the morrow may take thought for its own theories. These are not Liebig's words, but they seem to express his ideas.

Liebig early expressed his approval of Davy's views as to the constitution of acids, but he rarely used the language or the notation corresponding to that view. This divergence between his theory and his habitual language is interesting as showing that he held

that the same truth may be expressed in more than one way, and that where no immediate point is to be gained it is well to employ the language best understood by those whom we address. In this, as in his preference for what was called the equivalent system of notation over that of Berzelius, he showed his sound practical judgment and common sense. We now see that the notation of Berzelius was nearer the truth, but its advantages could not be felt until chemistry had advanced further, and its retention would have led to complications of formulae and obscuring of relations. The resemblance indeed of our present notation to that of Berzelius is to a great extent accidental, and the advance was hastened rather than hindered by what now looks like a retrograde step.

There is one other point which we have to mention under the present head. Liebig at once saw the importance of Graham's researches on the phosphates. He applied Graham's idea of polybasicity to organic acids, and it is too fully proved, notwithstanding the opposition of Berzelius, that tartaric acid is dibasic and citric acid tribasic.

We have hitherto said nothing as to the relation of Liebig's theories to those at present held by chemists. On this subject a word may suffice. The great revolt against the radical theory led by Laurent and Gerhardt produced a long and acrimonious controversy. In that controversy Liebig took his part, and many hard and some unfair things were said by him. The controversy itself was of course the means of producing a vast amount of thorough research, and was thus, like all such contests, of direct use. It added to the revision of all theoretical opinion from a totally new point of view. From this ordeal the radical theory has emerged, not very different in appearance. But it has undergone a profound change. Its foundations have been immensely strengthened; it has been to a great extent explained. Some chemists seem to think that this makes it an entirely new theory. We cannot share this view. Our reasons for believing in ethyl and benzoyl differ from the reasons adduced by Wohler and Liebig only in this that we have arguments which they had not; then arguments remain. We now know something of the reason why such radicals exist; we can, to a certain extent, deduce their properties from those of the elements which they contain, but explanation is something different from refutation; the theory has grown, but still remains the same theory.

Liebig all his life showed a special predilection for the study of the immediate products of animal life. He investigated with untiring zeal the substances contained in urine and in the juice of flesh. In these researches he discovered many new substances, and cleared up doubts and difficulties as to their relations to one another and to other bodies. Late in life he expended the most lively interest in Volhard's synthesis of sucrose and creaming substances with the preparation of which he had long before been engaged. In this connexion it is right that we should mention his elaborate investigation on urea and its derivatives. This line of study led him to interest himself in the chemistry of food, and the importance of his work in this direction can hardly be overestimated. We do not refer alone to his methods of preparing the extract of meat and the food for infants, which have perhaps spread his fame more widely than his strictly scientific work could have done; we refer rather to the influence which his analyses and calculations have had on medical opinion and practice. And this leads us to our fifth head, Liebig's influence on the application of chemistry to physiology, agriculture, and the arts.

Before Liebig undertook his investigations into the chemistry of vegetation, the views (they can scarcely be called theories) held as to the manner in which plants are nourished were vague in the extreme. The only point satisfactorily made out was that under the influence of light the green parts of plants are capable of decomposing carbonic acid, giving off oxygen and retaining the carbon. Sansone, to whose careful experiments the establishment of this fact, first noticed by Priestley, is mainly due, believed that the nitrogen of the plant came from soluble organic substances absorbed by the roots, and expressly stated that the name use of ammonia in manure is as a solvent of these, which he supposed to be one source of the carbon of plants; and, although the ashes of the various plants had been analysed, the importance of the mineral constituents of vegetables was not at all recognized. Liebig undertook the investigation of this question in 1840. He showed that the plant derives its nourishment partly from the air, partly from the soil; the carbonic acid and water, the ammonium and nitric acid, which he showed to be the sources of the plant's nitrogen, come from the atmosphere; while the potash, soda, lime, iron, magnesium, sulphuric acid, phosphoric acid, and silica come from the soil. No exhaustion can take place of the former, but the soil contains only a limited amount of the latter in a soluble state, and when this is used up the soil becomes barren. Not only so, but the use of any one of the necessary substances makes the soil barren. He showed how manure acts by restoring these deficient ingredients, and how, when the land is left fallow, atmospheric influences decompose the insoluble minerals and supply the soil with what has been removed. He further showed that plants use and therefore remove from the soil the articles of plant food in various proportions,

and thus explained the advantage of a rotation of crops. The artificial manures which he introduced contained the essential mineral substances, and a small quantity of ammoniacal salts, because he held that while the air supplies ammonia it does not always supply it fast enough, particularly to the less leafy plants. He bought a field near Gießen for his experiments, and treated it with the artificial manure, but the result was disappointing. The manure was not inactive, but not nearly so active as it should have been. It was many years before he detected the cause. To prevent the rain washing away the alkalies in the manure, he had taken great pains to render them insoluble. Way's experiments on the absorption of manure by soils (1850) occurred to him as suggesting an explanation, and in 1857 he made a number of experiments on the retention of various substances by earth. In these he confirmed and extended Way's observations, and thus saw that his effort to make his manure better had made it worse. As he says, "I had sinned against the wisdom of the Creator, and received my righteous punishment. I wished to improve His work, and in my blindness believed that, in the marvellous chain of laws binding life on the earth's surface and keeping it always new, a link had been forgotten which I, weak powerless worm, must supply."

Now, just as he showed that plants require certain—often small—quantities of particular substances, else they will not grow at all, however great may be the quantities of other kinds of food supplied, so he showed that animals also require, not only a proper quantity of food, but also the right proportion of the different kinds of food, mineral as well as organic. In the classification of the kinds of organic food into heat-producing and blood-forming, it was necessary to examine whether the carbohydrates, starch, sugar, &c., should be placed alongside of fat. He was thus led to inquire into the power of the animal body to produce fat from starch or sugar, and came to the conclusion, contrary to the opinion of Dumas and Boussingault, that this transformation does take place.

Liebig's investigations into the relations of organic chemistry to physiology led him to the conviction that the only source of animal heat is the heat produced by the oxidation of the tissues, and, strange as it may appear, he had to defend this view against what he truly enough, though perhaps somewhat impolitely, called the absurd nonsense of his medical opponents. He also succeeded in demolishing, it is to be hoped finally, the ridiculous belief in the possibility of the spontaneous combustion of the human body.

Liebig's theory of FERMENTATION (*q.v.*) aimed at explaining the phenomena on purely chemical principles. He ridiculed the physiological theories, and looked upon the growth of fungi rather as incident of the fermentation, adding the fermentative changes of amygdaline and similar substances as cases of fermentation without life.

We have still to notice one of Liebig's chemical discoveries, of secondary interest chemically, but of great practical importance. This is his discovery of a method for depositing a uniform film of metallic silver on smooth clean surfaces. This method may render it possible to use reflectors for astronomical telescopes of a size unattainable with the old speculum metal.

The most important of Liebig's works separately published are as follows:—*Anleitung zur Analyse organischen Körper*, 1837, 2d ed., 1853; *Die Chemie in ihrer Anwendung auf Agricultur und Physiologie*, 1840, 9th ed., 1875-76; *Die Thierchemie oder die organische Chemie in ihrer Anwendung auf Physiologie und Pathologie*, 1842, 3d ed., 1847; *Handbuch der Chemie mit Rücksicht auf Pharmacie*, 1843; vol. 1. of Geiger's *Handbuch der Pharmacie*, new ed.; *Chemische Briefe*, 1844, 6th ed., 1878; *Chemische Untersuchungen über das Fleisch und seine Zubereitung als Nahrungsmittel*, 1847; *Grundsätze der Agriculturchemie*, 1855; *Zur Theorie und Praxis der Landwirthschaft*, 1856; *Naturwissenschaftliche Briefe über die moderne Landwirthschaft*, 1859; *Veden und Abhandlungen*, 1871, a posthumous collection of some of his addresses and shorter publications. Liebig's scientific papers were chiefly published in Poggenhoff's *Annalen* II 1839, and in Liebig's *Annalen* from 1832 onwards. His criticism of Bacon appeared in the *Augsburger allgemeine Zeitung* in 1863 and 1864, and also as a separate publication. (A. C. B.)

**LIECHTENSTEIN**, a sovereign and independent principality, the smallest in Germany, is bounded on the N.E. and E. by the Austrian Vorarlberg, on the S. by the Swiss canton of Grisons, and on the W. by the Rhine, while on the north it tapers almost to a point. The state, consisting of the lordships of Vaduz and Schellenberg, is only 15 miles in length, hardly over 5 miles in its average breadth, and comprises an area of 68 square miles. Excepting in the immediate neighbourhood of the Rhine, the surface of the country is mountainous, being traversed from south to north by spurs of the Rhatian Alps, which at some points attain an altitude of about 7000 feet. The climate is mild, and the soil generally fertile and well watered. The chief products are corn, wine, flax, fruit, and timber. Agriculture and the tending of cattle form the chief employment of the inhabitants. A branch of the Vorarlberg railway from Feldkirch to Buchs passes through

the state. In 1876 the population amounted to 8664, of old German extraction, and Roman Catholics by confession. The capital is Vaduz or Liechtenstein, with 960 inhabitants.

Until 1866 Liechtenstein formed part of the German confederation, but from that date it has been constitutionally independent, although for the sake of convenience the postal system, customs, and currency are under the general Austrian administration, from which the principality receives annually some £1600 as its share in the customs dues. According to the charter of the 26th September 1862, Liechtenstein is a constitutional monarchy, the sovereign prince sharing the legislative power with a diet of fifteen members (elected sexennially), of whom three are nominated by the prince, and twelve elected by popular suffrage. The chief control of the principality is carried on at Vienna by a court chancery, which also serves as the judicial court of appeal of first instance, the ultimate court of appeal being at Innsbruck. The immediate direction of the principality in administrative and judicial matters is at Vaduz. The inhabitants are free from military service and direct taxation. The annual revenue amounts to about £6000. Although the sovereignty of the prince is so small, his estates in Austria and elsewhere render him one of the wealthiest landed proprietors in Germany, his income from them amounting to nearly £140,000 sterling. The house of Liechtenstein, one of the oldest in Central Europe, was elevated to the princely dignity in the early part of the 17th century. Anthony Florian in 1713 obtained a vote and seat in the imperial diet, and after the union, in 1719, of the lordships of Vaduz and Schellenberg into one principality under the name of Liechtenstein, his privileges were, in 1723, confirmed to his successors. See Jacob von Falke, *Geschichte des fürstlichen Hauses Liechtenstein*, 2 vols. (Vienna, 1868-77).

**LIÈGE** (Germ., *Lüttich*; Dutch, *Luik*; Walloon, *Lige*; usually Latinized as *Lodivium*), a city of Belgium, the chief town of the province of Liège, is situated in 50° 39' N. lat. and 5° 31' E. long., 56 miles east of Brussels (62½ by

'Plan of Liège.

rail), and 16 miles south-south-west of Maastricht. It occupies a remarkably fine position on the banks of the Meuse, which at this point is joined by the Ourthe. On the left-hand side stands the older city with the citadel and the more important historical buildings; on the right hand lies the lower and more modern portion, commanded by the fort of the Chartreuse. The river, there 460 feet across, is spanned by several bridges, of which the Pont des

Arches, rebuilt in 1860-63, dates originally from the 8th century, and plays a prominent part in the local annals. Place St Lambert is the historical centre of Liège. Here still stands the noble building—erected (1508-40) by Cardinal de la Marck in a late Gothic style—which down to the revolution was the palace of the prince-bishops, and is now with its modern extensions occupied by the public courts and other administrative offices. And here, till it was ruined by the revolutionists in 1794, and completely removed in 1808, stood the old cathedral of St Lambert, originally founded in 712, and rebuilt after a great fire at the close of the 12th century. The rank of cathedral was in 1802 transferred to the abbey-church of St Paul, the foundation of which is assigned to 968, though the nave is no older than the 16th century, and the choir belongs to 1280. The stained glass and the wood carving of the pulpit by Geefs deserve particular mention. Other churches of note are St Jacques, a fine Gothic building founded in 1016, with a Romanesque west tower and a polygonal choir; St Barthélemy, a completely modernized basilica of the 12th century; St Martin, founded in 962 and rebuilt in the middle of the 16th century; and the Holy Cross, founded by Notker in 979, with a west choir dating from the 12th century, and the east choir and nave from the 14th. The university of Liège, established in 1817, is a flourishing institution with about 40 professors and 800 students, a library of 100,000 volumes, a botanic garden (1819, formerly the Jesuits' garden), a school of mines (1825), a school of arts and manufactures, a normal grammar school, and several other auxiliary foundations. There is no theological faculty,—the theological seminary, with a large library of its own, being an independent institution. The city further possesses a blind asylum, a deaf and dumb institute, schools of design, painting, and music, a zoological garden, a municipal museum, &c. The Place d'Avroi is adorned by an equestrian statue of Charlemagne by Jehotte; and in front of the theatre stands a bronze statue of Gretry, the composer, who was born at Liège.

Liège is the centre of a great mining district rich in coal, lead, zinc, and iron; the coal-mines extend under the city and the river. In 1879 358,100 tons of coal were raised in the province, 22,156 persons being employed in the pits. The iron, lead, and zinc foundries in the town and neighbourhood work up large quantities of ore in addition to the products of the mines. Steel, copper, and tin wares, steam-engines and general machinery, woollen goods, excellent saws and files, nails, needles, mirrors, clocks, leather, paper, and oil are among the products of the versatile industry of the place. Liège firearms have long enjoyed a wide reputation. They give employment to about 30,000 workmen, who for the most part work in their own houses, though in 1878 a large factory was erected in the American style for making all parts of the weapon by machinery. In 1878 183,806 single-barrelled guns, 113,121 double-barrelled guns, 408,649 revolvers, 19,395 saddle pistols, and about 85,000 army weapons, &c., were passed by Liège through the Government testing office. The trade of Liège is favoured by the fact that the town is an important junction on the Rhenish Belgian Railway, commands more than one navigable river, and has long been one of the leading cattle-markets in the country. The population was 115,956 in 1874.

About 720 the bishops of Tongres, after oscillating between Tongres and Maastricht, settled at Liège, though they did not take the title bishop of Liège for more than two centuries. Their church of St Lambert received large territorial endowments, and in the 14th century they became princes of the empire. For centuries the struggle was maintained between episcopal tyranny and civic independence; and ducal and imperial armies were called in to crush the insurrections. In this way Charles the Bold of Burgundy made himself master of the city in 1467, and again with much bloodshed and barbarity in 1468. Bishop Ferdinand in 1650 and Bishop Maximilian in 1684 were each imposed on the citizens by force of arms, and kept them down by means of a strong citadel and foreign soldiers. In 1691 Liège was bombarded for five days by Marshal de Boufflers; in 1702 Marlborough took the citadel by storm from a French garrison; and in 1792 the town was the scene of a great defeat of the Austrians by the French.

LIEGNITZ, the capital of a district of the same name in the Prussian province of Silesia, is picturesquely situated on the Katzbach, just above its junction with the Schwarzwasser, and 40 miles west-north-west of Breslau. It consists of an old town, surrounded by pleasant, shady promenades, and several well-built suburbs. The most prominent building is the palace of the former dukes of Liegnitz, rebuilt after a fire in 1835, and now occupied by the administrative offices of the district. The Ritter Academie, founded by the emperor Joseph in 1708, for the education of the young Silesian nobles, was reconstructed as a gymnasium in 1810. The Roman Catholic church, with two fine towers, contains the burial vault of the dukes. The principal Lutheran church dates from the 11th century. There are also several other churches and schools, and a number of benevolent institutions. The theatre, the barracks, the military hospital, and the town-house are the most noteworthy of the remaining buildings. The manufactures of Liegnitz are considerable, the chief articles being cloth, wool, leather, tobacco, and pianos. Its trade in grain and its cattle-markets are likewise important. The large market gardens in the suburbs grow vegetables to the value of £20,000 per annum. Population in 1880 37,168, about one-sixth being Roman Catholics.

Liegnitz is first mentioned in an historical document in the year 1004. In 1161 it became the seat of the dukes of Liegnitz, who greatly improved and enlarged it, especially in 1170 and 1175. The dukes were members of the illustrious Piast family, which gave so many kings to Poland. At Wahlstatt, near Liegnitz, the tide of Mongolian invasion was stemmed, in 1241, in a hard-fought battle between the Tatars and the Christian chivalry under the duke of Silesia. The victory, indeed, remained with the invaders, but the obstinate resistance deterred them from any further attack on Germany. During the Thirty Years' War Liegnitz was taken by the Swedes, but was soon recaptured by the Imperialists. The Saxon army also defeated the imperial troops near Liegnitz in 1634. On the death of the last duke of Liegnitz in 1675, the duchy came into the possession of Austria, which retained it until the Prussian conquest of Silesia in 1740-45. In 1760 Frederick the Great gained a decisive victory near Liegnitz over the Austrians near Landau, and in 1813 the list of important battles in this neighbourhood was completed by Blücher's defeat of the French at the battle of the Katzbach. During the present century Liegnitz has been uniformly prosperous, and its population has increased fivefold since 1800.

See Schuchard, *Die Stadt Liegnitz* (Dolfin, 1868); Schmiter and Kradoff, *Chronik von Liegnitz* (Liegnitz, 1861-73).

LIEN, in English and American law, properly means a right of detaining goods of another in your possession until a debt due to you from the owner of the goods is paid. To the original or common law conception of a lien it would appear to be necessary that the goods over which lien is claimed should be actually in the possession of the creditor, and further that the debt should have been incurred with reference to the goods which are detained. Such is the lien of the workman to whom articles are delivered for the purpose of being operated upon by him in the way of his trade. He is entitled to keep the article he has worked at until remuneration for his labour has been made to him. Of precisely the same character is the lien of the carrier over the goods conveyed by him, for the fare; of the farrier over the horse which he has cured, for his fee; of blacksmiths, shipwrights, and other artificers for the wages they have earned by working at or on the thing detained. This, the true lien of the English law, is denominated a particular lien in contradistinction to a right of detainer exercisable over the property of another for a debt not incurred in relation to the thing detained. The latter is a general lien. The former is said to be favourable, the latter strictly construed by the law. The former arises by implication of law from the relation of the parties; the latter requires a special contract either expressed in terms or to be inferred from the usage of trade. Again, as possession is the foundation of lien in common law, a parting with the possession would in general operate as a waiver

or forfeiture of the lien. The same effect would follow of course from any agreement by the lien holder to give up his right while retaining possession of the property. Again as a general rule lien means only a right of detention, not a power of sale,—a fact which distinguishes it from a pledge of property in security for a loan. But in special cases powers of sale have by statute or judicial decision been added to liens. Thus innkeepers now have, in addition to their ordinary right of lien, power to sell

and chattels left with them after six weeks (41 & 42 Vict. c. 38). In the United States the principle of the particular lien has been developed in a notable manner in protecting the rights of workmen employed in building. At common law, the building belongs absolutely to the owner of the soil; and accordingly, when a house is erected by contract, the contractor may receive payment from his employer and may fail to pay the labourers he has employed, who are consequently left without redress. The "mechanics' liens," created by statute in several of the American States, give labourers a lien over the building which they have erected for their unpaid wages. Notice having been filed in the prescribed manner, they acquire a right to have their wages paid out of the property, which may if necessary be sold for that purpose. A similar preferential charge, not depending on possession, is recognized by the law in various cases, and goes by the name of lien. Thus in equity an unpaid vendor has a charge for the amount of the purchase money, or the balance thereof, over the estate, although it may no longer be in his possession. Charges of this kind are sometimes denominated equitable liens. Of the same nature is the charge acquired over a ship by a person who has supplied her with necessaries for the voyage under a lawful contract with the master (*maritime lien*).

LIERRE, or L'ER, a town of Belgium, in the province of Antwerp, 9½ miles south-east of Antwerp (on the railway to Malines), at the junction of the Great and Little Neeffe. It is a busy place of 15,659 inhabitants (1874), and manufactures silk, lace, and shoes, beetroot sugar, and a peculiar kind of white beer known as *casse*. The church of St Gommarius (in plan a Latin cross with a lofty tower in front) is one of the most notable buildings of its class in Belgium. It was commenced in 1425, but not completed for more than a century. Of the fine stained glass windows three were presented by the emperor Maximilian.

Lierre, which dates from the 6th century, owed much to the favour of the dukes of Brabant, to whose territory it belonged. The more important facts in its annals are the celebration of the marriage of Philip the Fair with Joanna of Castile (1496); the residence in the town of Christian II. of Denmark during his exile; and the contests between the Dutch and Belgian forces in 1830. Joseph II. ordered the fortifications to be razed in 1784.

**LIFE ASSURANCE.** See **INSURANCE.**

**LIFEBOAT.** It will be convenient to consider here, not the lifeboat simply, but also other means of saving life at sea. When it is borne in mind that the vast commerce of such a country as Great Britain extends to every part of the world, that the arrivals and departures from the ports of the country in one year average six hundred thousand vessels, that these are manned by more than two hundred thousand men and boys, and carry goods to the estimated value of six hundred millions sterling, with unknown thousands of passengers, that its seaboard is nearly 5000 miles in extent, many parts of it being exceedingly dangerous to shipping, that about two thousand wrecks occur every year on its shores, and above seven hundred lives are lost, the necessity that exists for a well-organized system of life-saving apparatus becomes very apparent. It is satisfactory to be able to add that this well-organized system is most efficiently provided by the Royal National Lifeboat Institution, with its splendid fleet

of two hundred and seventy-one lifeboats, and by the Rocket Service. The number of lives saved annually, either by the lifeboats or by special exertions for which the institution has granted rewards, averages in round numbers nine hundred, and by far the greater proportion of these (four-fifths) are saved by lifeboats. These lifeboats, too, are the means of saving every year from twenty to thirty vessels which, owing to stress of weather, exhausted men, &c., would almost certainly have been lost but for the aid afforded by the fresh and experienced lifeboat crews.

The qualities of the lifeboat first deserve our attention. These are such that this boat is able to live in seas, and go into positions of danger, that would overwhelm ordinary boats or insure their destruction. Eight important qualities are possessed by it in a very high degree:—(1) buoyancy; (2) great lateral stability, or resistance to upsetting; (3) the power to right itself if upset; (4) the power of immediate self-discharge when filled with water; (5) strength; (6) stowage room for a large number of passengers; (7) speed against a heavy sea; (8) facility in launching and taking the shore.

The *buoyancy* of the institution's lifeboat, or its inability to sink, be it ever so deeply laden, is secured chiefly by means of a watertight deck or floor, air-cases round the sides inboard, and two large air-chambers, one in the bow, the other in the stern. The "extra buoyancy" thus obtained cannot be too great so long as it does not interfere with the space necessary for working the boat and stowing shipwrecked persons. The air-cases round the sides serve also to confine any water shipped to the centre of the boat, a point of great importance. There is an air-tight space between the boat's floor and its bottom, filled partly with air partly with cork-ballast, which gives it additional buoyancy, but the air-chambers above the floor would float the boat even if she were stove in and this space filled with water. In a 33-foot boat the buoyancy obtained by all its chambers is equal to 11½ tons.

*Stability* is obtained chiefly by means of ballast. Immense difficulty was experienced in arriving at the present form of the institution's splendid boat, because qualities of differing value had to be sacrificed to each other in due proportion. Thus, while breadth of beam secured stability, it seriously interfered with the *self-righting* quality. Ballast, therefore, in the form of a heavy iron keel, instead of breadth, became necessary to give the requisite stability.

Fig. 1 represents let us say, the 33-foot, double-banked, ten-oared, self-righting, and emptying lifeboat of the institution in its transporting carriage ready for launching; figs. 2 and 3, respectively, a section and a bird's-eye view of the same. The

FIG. 1.—Ten-Oared Lifeboat.

breadth is 8 feet, with stowage room for forty-three persons—thirty passengers and thirteen off a crew. The festooned lines (fig. 1) enable people in the water to clamber inboard even without assistance. The shaded parts of figs. 2 and 3 show the position of the air-cases. The white oblong space in fig. 3 shows the free space available for crew and passengers. In fig. 2 are seen the depth to which the air-cases descend, and the height to which the bow and stern air-chambers ascend above the gunwale, also the ballast space between the floor and the keel.

The *self-righting* power is due to the large elevated air-chambers in bow and stern, coupled with great sheer, or rise fore and aft, of gunwale, to the iron keel, which weighs

about 9 cwts. in a 33-foot boat, and to the air-cases and ballast, which latter weighs from 7 to 8 cwts. When the boat is upset it cannot rest on its two elevated air-chambers; it necessarily rolls on one side, then the heavy iron keel and ballast come into play and drag it back to its right position

FIG. 2. - Lifeboat (Sheer Plan).

FIG. 3. - Lifeboat (Deck Plan).

in a few seconds. This principle of self-righting was discovered—at all events first exhibited—at the end of last century, by the Rev. James Bremner of Orkney, but was not finally adopted till the middle of the present century.

The *self-emptying* quality depends chiefly on the well known physical fact that water must find its level. The floor of the lifeboat (fig. 2, the dotted double line extending from stem to stern), on which the men's feet rest when seated on the thwarts, is placed so as to be very slightly—2 or 3 inches—above the level of the sea when the boat is fully manned and loaded. In this floor there are six holes of 6 inches diameter, into which are fitted six metal tubes. These pass through the boat's bottom into the sea. The water of course enters them, but cannot rise above them into the boat, because it cannot rise above its own level. Valves at the upper ends of the tubes, opening downwards, prevent the annoyance of water spouting in, but allow it freely to run out. When, then, a billow overwhelms the boat, and fills it, the water rushes violently down the discharging tubes until it reaches the sea-level; by that time it has descended below the level of the floor and left the boat empty. So complete and swift is the process that a filled boat frees herself in about half a minute. This principle was first applied by the institution in 1851. Lifeboats devoid of the self-discharging quality become temporarily useless when filled by a sea, as they can be emptied only by the slow and laborious process of baling.

*Strength*, that will enable the lifeboat to suffer treatment which no ordinary boat could stand, is dependent on peculiarity of construction and material. The best Honduras mahogany is used, and the diagonal plan of construction adopted,—that is, the boat has two distinct “skins” of planking, both sets of planks being laid on in a position diagonal to the boat's keel and contrary to each other, besides passing round from gunwale to gunwale under the boat instead of from stem to stern as in ordinary boats. The skins have a layer of prepared canvas between them, and thus great strength and elasticity are combined.

The *carriage* of the lifeboat is an essential adjunct for the purpose of conveying it over any kind of road or beach to the place where it may be required. It can be run deep into a raging surf, and the boat, with its crew seated and oars ready out, can be launched at once, by blocks and tackle, so as to enable the men to dash forward and meet the incoming rollers with sufficient force to propel it through or over the seas, and thus avoid the risk of being hurled back on the beach. Each lifeboat is furnished with a set of spare oars, as these are frequently broken.

The institution's lifeboats are of various sizes—six, eight, ten, and twelve oared,—and they are placed at various

points of the coast according to the necessities of each station. Some are called out at long intervals; others, such as those near the Goodwin Sands, are constantly on duty in rough weather—that of Ramsgate having a steamer to attend on it, which lies in harbour, with its fires banked up, ready for instant action night and day. The average cost of a lifeboat station is £1000,—the boat and equipments, including belts and carriage, costing £650, and the boat house £350. The average annual expense of maintaining a station is £70, which is expended in paying the crew for going off and saving or attempting to save life from shipwreck, for exercising the lifeboat once a quarter, paying coxswain's salary, replacing gear, and repairs.

The *lifebelt* of the institution is a part of the equipment of the lifeboat which merits special attention, because it is a very efficient contrivance, and has been the means of saving many lives in time past. Fig. 4 shows its appearance and the manner in which it is worn. It was designed in 1841 by Admiral J. R. Wood, the institution's chief inspector of lifeboats. It is made of cork fastened on canvas, and combines great buoyancy with strength and flexibility. It not only floats a man head and shoulders above water, but enables him to support a comrade easily.

The extra buoyancy being 25 lb. One of its distinctive features is its division at the waist, by which means great freedom of action is allowed. It serves also as a species of armour to protect the wearer's most vital parts from blows against rock or wreck while it affords some degree of warmth. No man may serve in the lifeboats of the institution without it, and it would be well if every British ship were supplied to every lifebelt of this kind.

*Hedera.* The first lifeboat was conceived and designed by Lionel Lukin, a London coachbuilder, in 1785. The idea occurred in his philanthropic plans by the prince of Wales, George IV. Lukin fitted up a Norway wharf as a lifeboat, took out a patent for it, and wrote a pamphlet descriptive of his “*Insurable Life Boat*.” By means of a leaden pipe, by means of a projecting gunwale, and other contrivances, he secured the boat from being upset, and the self-emptying principle he seemed not to have thought of; at all events he did not compass them. Despite the success of the project, Lukin went to his grave in neglected and poverty-stricken. But he was not altogether unsuccessful, for at the age of 70, the Rev. Dr. Stump, Lukin fitted up a cold-water lifeboat, which was launched at Ramsgate, and saved many lives and much property.

The first lifeboat of the “*Adventure*” of Newry was in 1789. This vessel was stranded only 300 yards from the shore, and her crew dropped, one by one, into the raging breakers in presence of thousands of spectators, some of whom dared to put out in an ordinary boat to the rescue. An excited meeting among the people of South Shields followed; a committee was formed, and proposals were offered for the best models of a lifeboat. This called forth many plans, of which three of William Wouldhove, a painter, and Henry Greathead, a boatbuilder of South Shields, were selected. The committee awarded the prize to the latter, and adopting the good points of both models, gave the order for the construction of their boat to Greathead. This boat was ordered buoyant by nearly 7 cwts. of cork, and had very raking stem and sternposts, with great curvatures of keel. It did good service in after years, and Greathead was well rewarded; nevertheless no other lifeboat was built till 1798, when the Duke of Northumberland ordered Greathead to build him a lifeboat which he endowed. This boat also did good service, and its noble owner ordered another in 1800 for Opot. In the same year Mr. Cathcart Dempster ordered one for St. Andrews, where, two years later, it saved twelve lives. Thus the value of lifeboats began to be recognized, and before the end of 1800 Greathead had built no fewer than thirty-one boats—eighteen for England, five for Scotland, and eight for foreign lands. That these boats were lamentably insufficient to meet the necessities of the day was shown year after year by the ever enlarging record of wreck and loss of life on her shores; nevertheless, public interest in lifeboats was not thoroughly aroused till 1823.

In that year Sir William Hillary, Bart., stood forth as champion of the lifeboat cause. Sir William dwelt on the tale of Man, had

FIG. 4.

assisted with his own hand in the saving of three hundred and five lives, and felt the horrors of shipwreck so keenly that he resolved to stir up public men and the nation generally to a sense of their duty in regard to this matter. Eventually, in conjunction with two members of parliament—Mr Thomas Wilson and Mr George Hibbert—he founded the "Royal National Institution for the Preservation of Life from Shipwreck." This, perhaps the grandest of England's charitable societies, and now named the "Royal National Lifeboat Institution," was founded on the 4th of March 1824. The king and many of the nobility and gentry patronized it. The archbishop of Canterbury presided at its birth; the most eloquent men in the land—among them Willerforce—pleaded the cause; the institution was launched under the most favourable auspices, and began its noble career with a sum of only £9826. In the first year twelve new lifeboats were built and placed at different stations, besides which thirty-nine lifeboats had been stationed on the British shores by benevolent individuals and by independent associations over which the institution exercised no control though it often assisted them. In its early years the institution placed the mortar apparatus of Captain Manby at many stations, and provided for the wants of sailors and others saved from shipwreck. The latter duty is now efficiently discharged by the "Shipwrecked Fishermen and Mariners' Royal Benevolent Society." At the date of the institution's second report it had contributed to the saving of three hundred and forty-two lives, either by its own life-saving apparatus or by other means for which it had granted rewards. With fluctuating success, both as regards means and results, the institution continued its good work from year to year—saving many lives, and occasionally losing a few brave men in its tremendous battles with the sea. District or branch societies were established in most of the coast towns. Ultimately it began to be recognized that inland towns owed something to the lifeboat cause, as well as towns on the coast, and now such cities as Manchester, Liverpool, Glasgow, Edinburgh, &c., have presented lifeboats to the institution and become annual contributors. Since the adoption of the self-righting boats, loss of life in the service has been comparatively small and infrequent.

Towards the middle of this century the lifeboat cause appeared to lose interest with the public, though the life-saving work was prosecuted with unremitting zeal, but the increasing loss of life by shipwreck, and a few unusually severe disasters to lifeboats, brought about the reorganization of the society in 1850. The late Prince Albert became vice patron of the institution in conjunction with the late king of the Belgians, and afterwards Her Majesty the Queen, who had been its patron since her accession, became an annual contributor to its funds. About the same time its present secretary, Mr Richard Lewis, barrister-at-law, was appointed. The following year (1851) the duke of Northumberland became its president, and from that time forward a tide of prosperity set in which is literally unprecedented in the history of benevolent institutions, both in regard to the great work accomplished and the pecuniary aid received. Its flow of prosperity has never since been checked. In 1850 its committee undertook the immediate superintendence of all the lifeboat work on the coasts, with the aid of local committees. Periodical inspections, quarterly exercise of crews, fixed rates of payments to coxswains and men, and quarterly reports were instituted, at the time when the self-righting self-emptying boat came into being. This boat was the result of a hundred-guinea prize, offered by the president, for the best model of a lifeboat, with another hundred to defray the cost of a boat built on the model chosen. In reply to the offer no fewer than two hundred and eighty models were sent in, not only from all parts of the United Kingdom, but from France, Germany, Holland, and the United States of America. The prize was gained by Mr James Beaching of Great Yarmouth, whose model, slightly modified by Mr Peake, one of the committee of inspection, became the foundation of the present boat, which, having been still further improved as time and experience have suggested, is now probably as near to perfection as can be attained.

The shortest way, perhaps, to exhibit the progressive work of the institution is to contrast the report of 1850 with that of 1880. In the former year the receipts had dwindled down to £84 of subscriptions and donations, which, with £270 of dividends (on a capital of £3000) and a balance of £176 on hand, gave an available income of £530. The expenditure was £590, and the lives saved were about one hundred. In 1850 donations and annual subscriptions amounted to £29,219; dividends and interest (on a capital of £231,000) amounted to £9266. The total income was £38,506, besides legacies in the same year to the amount of £40,782. The expenditure, including liabilities, was £40,586, and the number of lives saved was about seven hundred. In the past unusually disastrous year (1881), the institution has saved 966 lives by its boats, and granted rewards for the saving of 155 more, besides rescuing 33 vessels from destruction. The total number of lives saved either by the lifeboats, or by special exertions for which the institution has granted rewards, since its formation, is 28,724, for which services 95 gold medals, 939 silver medals, and £69,000

in cash have been granted as rewards. So highly are the services of the institution appreciated that donations of boats, gifts of money, acknowledgments, and legacies come in from nearly all quarters of the globe, in sums varying from a shilling to £10,000.

**Rocket Apparatus.**—This, next to the lifeboat, is the most important and successful means by which shipwrecked persons are rescued on the British shores. Many vessels are cast every year on the rocky parts of the coasts, under cliffs, where no lifeboat could be of service. In such places the rocket alone is available. It is worked by the men of the coastguard, with the aid, in a few places, of volunteer rocket brigades. The courage and skill displayed in its use are evinced by the saving of many lives every year, and by the fact that a large proportion of the medals given by the lifeboat institution for heroic conduct are awarded to the men of the coastguard, who, besides managing the rockets, frequently man the lifeboats and also effect rescues in their own boats. The number of lives saved by means of the rocket apparatus in the year ending 30th June 1881 was 657. This, however, is the greatest number saved in any one year since 1856, at which date the life-saving rocket apparatus was placed under the entire control and management of the Board of Trade. The rocket stations on the coast at the 30th June 1881 numbered 288. The Board of Trade now gives a sum of money for each life saved, besides awarding silver and bronze medals for acts of special gallantry.

The apparatus consists of five principal parts, viz., the rocket, the rocket-line, the whip, the hawser, and the sling lifebuoy. The mode of working it is as follows. A rocket, having a light line attached to it, is fired over the wreck. By means of this line the wrecked crew haul out the whip, which is a double or endless line, rove through a block with a tail attached to it. The tail-block, having been detached from the rocket-line, is fastened to a mast, or other portion of the wreck, high above the water. By means of the whip the rescuers haul off the hawser, to which is hung the travelling or sling lifebuoy. When one end of the hawser has been made fast to the mast, about 18 inches above the whip, and its other end to tackle fixed to an anchor on shore, the lifebuoy is run out by the rescuers, and the shipwrecked persons, getting into it one at a time, are hauled ashore. Sometimes, in cases of urgency, the lifebuoy is worked by means of the whip alone, without the hawser. A tally-board with instructions to wrecked crews, printed in English and French, is sent off with the whip, as ignorance in regard to the mode of working the apparatus has been the cause of much loss of life. Such ignorance is culpable, because the Board of Trade issues enamelled plates with instructions, which are supplied gratuitously to shipowners and masters to be placed on conspicuous parts of their vessels, and are fixed in public places along the British coast, while every certificated officer in the mercantile marine is required to understand the working of the rocket apparatus.

The late Captain G. W. Manby, F.R.S., in 1807 invented, or at least introduced, the mortar apparatus, on which the system of the rocket apparatus is founded. Previously, however, in 1791, the idea of throwing a rope from a wreck to the shore by means of a shell from a mortar had occurred to Serjeant Bell of the Royal Artillery, and about the same time, to a Frenchman named La Fère, both of whom made successful experiments with their apparatus. In the same year (1807) a rocket was proposed by Mr Trengrouse of Helston in Cornwall, also a hand and lead line as means of communicating with vessels in distress. The *heaving-line*, a fruit of the latter suggestion, is now used at every station in the kingdom. In 1814 forty-five mortar stations were established, and Manby received £2000, in addition to previous grants, in acknowledgment of the good service rendered by his invention. Mr John Dennett of Newport, Isle of Wight, introduced the rocket, which was afterwards extensively used. In 1826 four places in the Isle of Wight were supplied with Dennett's rockets, but it was not till after Government had taken the apparatus under its own control, in 1855, that the rocket not in use was adopted. It was invented by Colonel Boxer, and its peculiar characteristic lies in the combination of two rockets in one case, one being a continuation of the other, so that, after the first compartment has carried the machine to its full elevation, the second gives it an additional impetus, whereby a great increase of range is obtained. The rocket has now entirely superseded the mortar in England.

The United States Life-Saving Service is chief among the lifeboat societies of other nations, both as regards the extent of coast embraced and the amount of work done. There are several points of difference between this service and that of England which are noteworthy. In the first place the whole or nearly the whole of its

support is provided for by annual grants of money from Congress. Secondly, besides protecting its vast extent of seaboard, it has to provide for the shores of its great lakes, or fresh-water seas. Then, the coasts of America, unlike those of England, are destitute of human habitations in many places, which renders necessary the constant employment of surfmen for the express purpose of looking out for vessels in distress and manning the surf-boats. It also necessitates the erection of houses of refuge, provisioned so as to afford shelter and food to shipwrecked crews for a considerable time, at places where, without such provision, those who escape the sea would probably perish from hunger and exposure.

The shores of the United States—lakes and sea—are over 10,000 miles in extent, embracing almost every variety of climate and formation of land. This vast extent of coast-line is divided into 12 districts, with a total of 179 stations. Of these 139 are on the Atlantic, 34 on the lakes, and 6 on the Pacific. Those on the desolate coast of Florida are houses of refuge only, without boats or apparatus. Many of the stations are closed during the fine months of the year, their crews being disbanded till the winter gales again summon them to the heroic and dangerous work of saving the shipwrecked. That they render noble service in this way may be gathered from the annual reports. The report for 1880 shows that the disasters to shipping in that year amounted to 300, that on board of the vessels thus endangered there were 1989 persons, of whom 1980 were saved and only 9 lost. The property imperilled at the same time was estimated at, in round numbers, £790,000, of which over £540,000 worth was saved, besides which, in one hundred and twenty-eight instances, stranded vessels were hove off, and piloted out of danger by the surfmen. The total number of lives saved by this service, since the introduction of the present system in 1871, to the close of the fiscal year in June 1881, was 11,864; the total number of persons sheltered 2610, and the number of days' shelter afforded 7350; the total value of property saved, \$14,958,875.

Owing to the flat shores of the Atlantic coast, and the sparseness of the population, heavy boats are found unsuitable. Only a few boats on the English model exist in the service. The boats chiefly in use are surf-boats, incapable of self-righting, and liable to be swamped, but which nevertheless seem well suited for the work, and are admirably managed. They are very light, and can, on their transporting carriages, be easily dragged along the shore by their crews. The cork life-belts worn by the men are of the plan first designed in 1854 by Rear-Admiral Ward. For projecting a line over a stranded vessel, the Americans prefer the mortar, or other piece of ordnance, to the rocket. In addition to the travelling life-buoy, they use a metallic car, or small covered boat, which can hold three or four persons, who, entering it by a small manhole, are shut in and drawn ashore, safely protected from injury, even though overturned by the surf. This clever contrivance has been of great service in rescuing invalids, children, and aged persons. The total cost of the service is somewhere about £90,000 a year.

The history of the United States Life-Saving Service may be said to have begun in 1848, though half a century before that the Humane Society of Massachusetts had secured some bits of shelter and stationed some boats on the coast. In that year the United States Government was led to consider the subject of loss on their shores, chiefly through the energy of the Hon. W. A. Newell of New Jersey, a member of the House of Representatives. Captain Douglass Offinger (the inventor of the life-car) was charged with the management and reconstruction of the service. The impetus given to it at this time was never quite lost. Again, in 1854, renewed efforts were made to improve the service, but no great progress was made till the year 1871, when the present effective system was organized; new stations were built; the patrol system between the stations was introduced; the regular keeping of journals and sending in of reports was ordered; libraries for the use of the men were sent to stations; uniformity in signals was arranged, and a thorough reform in all departments accomplished.

The French Society for Saving Life from Shipwreck, modelled on the basis of the English system, is a vigorous and healthy offshoot. It continues steadily to extend its operations along the coasts of France, besides introducing its life-saving apparatus into Algeria and other colonies. It was founded in the year 1865, and from that year onward has continued to do good and ever-increasing service in the saving of life and property. At the date of its report ending 30th June 1881, its lifeboat stations numbered 62, and its mortar or other projectile stations 391. During the year its lifeboats and gun apparatus had saved 209 lives and 16 ships, to which may be added 31 lives, for the saving of which the society had granted rewards. From the time of its commencement in 1865 to the above date it has rendered the following noble service:—

Lives saved by its own boats and apparatus .....	1,826
Lives saved by other means, for which the society granted rewards in gold, silver, and bronze medals, and cash .....	303

Total of lives saved from the beginning ..... 2,129

Besides this it has saved 149 vessels and succoured 348, and has awarded 28 gold, 129 silver, and 319 bronze medals, 513 diplômes d'honneur, and about £20,400 in recompenses to those who have assisted in saving life in circumstances of unusual danger. It has also spent about £53,000 in the purchase and repair of its matériel. The receipts of the society show that its work is appreciated. At 31st December 1880 the subscriptions and donations together amounted to nearly £2600, and the legacies bequeathed to it the same year were about £1000. The boats chiefly used are built on the model of those of the English institution. The gun is preferred to the rocket in connexion with the life-saving apparatus. In addition to its direct work of saving life, the French society has accomplished much good indirectly by its influence. It has been instrumental in bringing about this result that, among the qualifications for a captain's certificate in the French mercantile marine, a thorough knowledge in detail of the means of saving life from shipwreck is required. It has also laboured to extend the usefulness and reduce the cost of the gun and rocket apparatus, besides securing that this apparatus, on Mr Delvigne's system, shall be supplied to every ship of the French navy.

The German Association for the Rescue of Life from Shipwreck, under the patronage of the emperor William, was founded at Kiel in May 1865, and is prosperous both in regard to its work and finances. It is maintained by voluntary contributions, and has 21 local branches on the coast and 27 in the interior, besides 149 agencies over the country. Previous to 1865 several private societies for saving life from shipwreck existed in the chief seaports of the North Sea and Baltic. These have been absorbed in the present association, the proceedings of which are reported in a paper entitled *From Shore and Sea*, published at Bremen once a quarter, and largely modelled on the *Lifeboat Journal* of the English institution. The association provides the whole extent of the German coast with life-saving apparatus. It has 74 lifeboat stations, 20 of which are provided with the mortar or rocket apparatus. With these means it has, in the year 1880-81, saved 122 lives and 2 ships. The total number of human lives saved by the association since its commencement is 1181. From May 1880 to May 1881 the amount subscribed by its members was £57,000. As in America, the heavy self-righting and self-emptying boats of England have been found unsuitable to the thinly peopled and flat sandy beaches of Germany. Lighter and shallower boats have therefore been adopted. These are iron-plated and not self-righting, but almost impossible to capsize. The stations are visited at least once a year by an inspector, and the whole system seems to be well regulated and thoroughly efficient.

In addition to the above, lifeboat societies or other lifeboat organizations, formed more or less on the basis of the National Lifeboat Institution of Great Britain, are to be found in Russia, Italy, and Spain.

*Life-saving Hammocks, &c.* Various forms of buoyant mattresses, pillows, and india-rubber cloth life jackets and belts have been contrived. Among these may be specially mentioned the air lifebelt of Admiral Ward, which has four compartments, separately inflated, so that the puncture of one does not quite destroy the belt. Admiral Ryder's hammock also deserves notice. Its value lies simply in a cork mattress, which, when rolled up in its hammock, forms an efficient lifebuoy capable of supporting a man with his head and shoulders well above water, and it enables three men to float in an upright position. Cork mattresses are said to be cheaper and more comfortable than those stuffed with hair. Two such hammocks lashed together, about 20 inches apart, will enable two or three men to propel themselves easily through the water. The advantage of having such mattresses in a ship is obvious, for every one on board would be thus provided with a life-preserver.

It has also been suggested that the cushions of deck and cabin seats should, in a similar way, be made life-preservers, and that cabin furniture should be constructed so as to form rafts in cases of emergency. It is well to know, on the authority of the *Philosophical Magazine* (vol. xv. p. 362), that even a hat tied in a pocket handkerchief and held with the crown downwards may help to sustain a drowning man. It need scarcely be added that empty water-casks, tightly bunged, with ropes arranged for clinging to, form pretty good life-preservers. (R. M. H.)

LIFTS may properly be held to include all sorts of apparatus whose object is the lifting of weights. When the apparatus consists of comparatively small, separate, and portable pieces, it is called *lifting tackle*. When the lifting apparatus reaches that degree of size and complication that entitles it to be called *machinery*, there seems to be no general technical term that will include all kinds, but for the different classes of lifting machines there are such special names as *cranes*, *hoists*, *elevators*, *lifts*, *winding engines*, and *lift pumps*.

There is very little distinction made between hoists,

elevators, and lifts. The word *hoist* refers more particularly to machines used in warehouses and factories for raising goods from one story to another. They are worked by hand or by power, and are for comparatively light loads.

*Elevator* is used in two different senses. It refers to apparatus for lifting passengers to the upper stories of buildings. It also refers to the very different sort of apparatus used in grain-mills and storehouses for transferring the grain from one floor to another. The grain is drawn along channels or pipes, which are sometimes vertical and more often inclined, by means of a rotating archimedean screw, or of a strap continuously travelling upwards through the interior of the channel and carrying, fastened to it, a series of small buckets. Occasionally, if the inclination to the horizontal be small, a broad strap of the same width as the bottom of the channel runs along that bottom, and carries the grain with it simply lying on its upper surface. This latter method of transportation is more efficient, however, as a horizontal carrier or distributor than as a means of lifting. Grain might also easily be blown up a pipe by an air blast, but the writer does not know any instance of this method having been used. *Lifts* are constructed either for raising passengers in buildings or for heavier loads, such as freighted trucks and waggons, or the superstructure of bridges and large roofs during their erection.

In lifts or elevators, the working force is either hand, steam, or hydraulic power. Gas engines are unsuitable as direct sources of power for lifts, but they may be advantageously used to store hydraulic power in an accumulator from which water is supplied to work an hydraulic lift. Electricity has quite recently been used, but has not yet been tried sufficiently to allow of any valuable opinion being formed of its ultimate practical success.

The lift consists of (1) a box or "cage" to contain the persons or material to be raised; (2) a vertical square well or shaft, to the walls of which are attached guides to prevent the cage swinging to and fro; (3) a rope or chain by which to haul the cage upwards from above, or else a long rod or pillar by which to push it up from below; (4) a "barrel" or "sheave" over which to wind the chain or rope, and which is mounted on a shaft lying in bearings firmly supported by the building, or else a cylinder to contain water or steam to actuate the lifting rod; (5) mechanism through which the working power is transmitted to the barrel, or else water or steam piping connecting the cylinder above mentioned with the source of power; and (6) the driving engine or other source of power.

Most accidents happen to lifts through the hauling chain or rope breaking. For the sake of safety, therefore, particular care should be exercised in the choice of material for this part, and an appliance should always be attached to the cage whereby, if the rope breaks, the cage is caught immediately in whatever position it may be at the time of the breakage.

For light loads hempen ropes are sufficient and more convenient than chains, because they are noiseless in their action. If of the best quality (Manila) they are quite as reliable as ordinary chains, and an advantage claimed for them is that their gradual destruction by wear becomes easily apparent, and gives timely warning before they become dangerous, whereas the failure of a chain may take place without any easily visible previous sign having been given. For very heavy loads, however, chains or wire ropes should be used in preference to hempen ropes. Wire ropes may be made stronger for a given weight per foot of length than chains are, but unfortunately as commonly manufactured their quality cannot be certainly relied on. Like hempen ropes, they are almost noiseless.

To insure smoothness and noiselessness in passenger lifts, the sheave over which the rope passes is lined in the groove with leather.

For the sake of safety, the rope by which the cage hangs is often duplicated. Sometimes even three or four are used. In order that these should give additional safety, each rope must be capable of supporting the load by itself. Generally the load is lifted by one or other kind of power, and descends by the weight of the cage itself. This weight is always much more than sufficient for the purpose, and therefore counterpoises are introduced to balance the greater part of it, thus lessening the work to be done during ascent by an amount equal to the product of the balance weight and the height of the lift. In the commonest arrangement, the balance weights are hung on the same rope as that by which the cage is suspended. This passes over a pulley whose diameter is half the width of the well, so that the cage end of the rope rises vertically from the centre of the roof of the cage. This pulley is keyed on a horizontal shaft, which is driven by power from below, either directly by means of a rope or chain passing over another pulley, or else through intermediate spur gearing. The actual working rope is in this case not attached to the cage. Less frequently the rope from the engine forms one of the suspenders of the cage, the balance weights being attached by separate ropes.

The rope or chain by which the load hangs has to be so strong that its own weight is very considerable. A large excess of strength being more in demand in this kind of machinery than in other kinds, a greater stress than about 1 ton per square inch cannot be put upon the chain or rope (supposed to be of iron). This would make the rope weigh 3.4 lb per foot of length for every ton of load carried. If the height of lift were, for example, 60 feet, then, comparing the top and bottom positions of the cage, there would be in the former 60 feet less of rope on the cage side of the pulley, and 60 feet more on the counterpoise side, than in the latter position, so that if the counter-weight just balanced the load when the cage was at the bottom, it, along with the rope, would outweigh the cage in its highest position by the weight of 120 feet of rope, that is 408 lb for every ton of load, or nearly  $\frac{1}{4}$ th of the whole load. Since the ~~whole~~ load—that is, that of cage, ropes, and passengers or goods—is three or four and sometimes five or six times as great as the net load, this is a very serious increase on the *unavoidable* loss of balance resulting from the fact that the cage is alternately loaded and unloaded. The difficulty can be got over by extending the rope downwards from the balance weight to pass underneath a grooved pulley at the bottom of the well, and up from this to the under side of the cage, where it is attached. There will then be an equal length of rope always hanging on each side of the top bearing pulley; but an extra amount of friction occurs at the bearing journals due to the weight of the extra rope. The lower half of the rope may be of cheap inferior material, since there is very little stress upon it.

A precisely similar difficulty occurs if the cage be lifted from below by an hydraulic ram or piston-rod. Occasionally the weight of the cage and ram is left unbalanced. In this case the water pressure on the ram or piston has to support the whole load. Suppose the pressure in the reservoir from which the water is drawn to remain steady during the ascent, then evidently at the top of its stroke the water pressure on the ram is less than at the bottom of its stroke, by the weight of a column of water, of section equal to that of the ram, and height equal to the lift. Suppose, for example, that the water pressure at the level of the face of the ram in its highest position is 200 lb per square inch. Then for every ton of total load there must be provided about 11 square inches of piston area. A column of water of this horizontal section and 1 foot high weighs about 4.75 lb. This would give a difference of supporting pressure of 285 lb for every ton of total load in a lift of 60 feet,—that is, about  $\frac{1}{4}$ th of the total load. More commonly the weight

of the cage and the ram is balanced by counterpoises on chains fastened to the top of the cage and passing over a pulley overhead, while the water pressure is used to overcome only the friction, and the additional load of passengers or goods. In this case again, owing to the passage of the chains over the pulleys, the balance is disturbed in a rise of 60 feet, by about  $\frac{1}{10}$ th the weight of the cage and the ram, while the upward water pressure on the ram is in the same rise diminished by  $\frac{1}{10}$ th. The former disturbance of balance is a decrease of the load resting on the base of the ram, while the latter is a decrease of the supporting pressure on the same base. If these were made equal, the cage and load would be perfectly balanced in every position. To make them equal, it would be necessary simply to adjust the ratio of the part of the load borne by the counterpoise to the part borne by the water. Let the former part be  $W_1$  and the latter  $W_2$ , the total load being  $W_1 + W_2$ . Then for a water pressure of 200 lb per square inch, it would be necessary to have

$$\frac{1}{2}W_1 = \frac{1}{2}W_2, \text{ or } W_1 = \frac{1}{2}W_2 = \frac{1}{4}(W_1 + W_2).$$

For a pressure of 400 lb per square inch, the equation would be

$$W_1 = \frac{1}{4}W_2 = \frac{1}{5}(W_1 + W_2).$$

For 100 lb per square inch it would be

$$W_1 = \frac{1}{2}W_2 = \frac{5}{6}(W_1 + W_2).$$

This adjustment would necessitate a large unnecessary consumption of water, because the weight of cage and ram always bears a much greater ratio to the extra weight of passengers or goods than any of the above fractions  $\frac{1}{10}$ ,  $\frac{1}{5}$ , or even  $\frac{1}{2}$ . The adjustment being attainable by other means, this waste can in no case be desirable.

If a second cylinder stand beside the lift-well and be connected by a pipe to the cylinder directly underneath the cage, so that there is a continually open passage between the two cylinders, then the supporting rod underneath the cage, together with the column of water leading from its base through the pipes to the second cylinder, is the exact counterpart in compression of the overhead ropes in tension in the other class of machine; and, as counterweights are hung upon these ropes, a balancing weight may be laid on the surface of the water in the second cylinder. The balance weight, equaling that of cage and ram, rests on a plunger or piston fitting this cylinder, and the rod is extended upwards into a third smaller cylinder, on the plunger of which is admitted, by means of the valve worked from the cage or landing-platforms, an extra amount of water pressure suf-

Fig. 1.

Fig. 2.

ficient to elevate the extra load of passengers or goods. This is the arrangement in Tomassi's hydraulic balanced lift. The column of water which takes the place of the rope in the overhead arrangement passes from one cylinder to the other, and vice

versa, in the same way as the rope passes from the cage side to the counterweight side of the overhead pulley. Thus the balance, which may be made correct for one position of the lift, becomes disturbed for other positions by a similar amount to that already investigated. A perfect balance of the constant part of the total load, namely, that of the cage and ram, is, however, obtained for all positions of the cage by the arrangement shown in figs. 1 and 2. This is the design of Mr Edward Ellington, described by him in a paper read before the Institution of Mechanical Engineers in January 1882. The whole load is borne by the rod  $a$  underneath the cage, which enters as a ram into the vertical cylinder  $A$ . This rod is made solid in order to reduce the size of the cylinder as much as possible, and, therefore, of the size of the well that has to be bored in the ground to contain this cylinder. This class of lifts is especially expensive on account of this boring, and the objection to them on the score of expense is lessened by making the well small. The rod is made only just strong enough to safely bear the load on it. Its section should be designed with reference to the height of lift, because the longer the free length of the supporting pillar the greater is its tendency to buckle under a given load. If  $k$  be the stress per square inch calculated to be admissible in its section, and if  $W$  be the weight of cage and ram together and  $W'$  that of passengers or goods to be raised, the section is made equal to  $\frac{W + W'}{k}$ . Since

this same load has to be supported by the water pressure on the lower end of this rod, that water pressure must be equal to  $k$ . This cylinder  $A$  is kept always in open communication with the lower end of the cylinder  $B$ . In the same position connected to the top of the thick piston rod  $d$ . The pressure of the water enters into the third cylinder  $C$ , and to its lower extremity, and the large piston  $e$ . The pistons  $b$  and  $c$  are considerably shorter than the lift of the cage. The cylinder  $C$  is considerably shorter than  $A$ , and they stand above  $B$ . The strokes may range from 5 to 10 feet, and is the diameter of the under end of the piston  $b$  of the rod  $a$ , and  $a$  that of the rod  $c$ , and  $a$  that

of the cage to be lifted. Suppose the piston  $b$  to be at the top of  $A$ , and the cage to be at this position the piston  $b$  be at a height  $h$  above the lower end of  $a$  equal to  $h$  inches, and if  $w$  be the weight of a cubic inch of water, then, the pressure per square inch on the lower end of  $a$  is  $k$ . The whole upward pressure on this piston is then  $(k - hw)ba$ , and a downward pressure equal to or rather more than this must be exerted on this piston in order to lift the cage. This is supplied by admitting water from the main, or from the hydraulic accumulator if that plan is employed to provide water pressure, into the upper ends of cylinders  $B$  and  $C$ . The lower end of  $C$  is always kept in open communication with the atmosphere. The water is continually admitted to  $B$ , and the water pressure on the top surface of piston  $b$  is determined to balance the constant load of cage and ram when the piston is at the top of its stroke. During the ascent of the cage the water is admitted into  $C$  by a valve moved from the cage or platforms by means of the rope  $k$ , and the water pressure on the smaller top surface of piston  $c$ , when that piston is at its high position, is designed to balance the extra load of passengers or goods. During the descent, the cage being empty, the connection between  $C$  and the accumulator is shut by the valve, admitted from the cage, and the water is allowed to escape freely to the atmosphere, so that the pressure on  $c$  becomes equal to atmospheric pressure. If  $p$  be the pressure per square inch of the working water at the level of the piston  $b$  at its high position, and  $l$  be the length of plunger  $c$ , then in this position the whole downward force that is borne by the water underneath the piston  $b$ , and distributed over its area  $(b - a)^2$ , is  $p(b - a)^2 l$ , when the pressure on piston  $c$  is simply  $ph$  when the pressure is cut off from  $C$ . (To this should be added the weight of  $b$ ,  $c$ , and  $d$ , but for our present purpose of explanation only this may be left out of account.) The former quantity has to equal  $(k - hw)(b - a)^2 l$ , and the latter should equal

$$\left( \frac{W + W'}{W_1 + W_2} - hw \right) (b - a)^2 l.$$

These two equations serve to determine two of the quantities involved in terms of the others.

When the water pressure is admitted to the upper side of  $b$ , hence, the intensity of pressure on the under side of  $b$  is evidently many times greater than the intensity on its upper side as the area of its upper side is greater than that of its lower surface. Thus any increase of intensity on the upper surface will cause a correspondingly greater increase of intensity on the lower. Now if the pressure on the under side of  $b$  were to remain the same while the cage ascended, the pressure on the lower end of  $a$  would decrease by an amount proportional to the change in the difference of level. If, for example, the ratio of the stroke  $l$  to the diameter of level of the cage rises 6 inches,  $b$  will fall 1 inch, and the difference of level

between  $b$  and  $a$ , will be decreased 7 inches. The pressure per square inch on  $a$  would decrease  $7w$  if that on the under side of  $b$  kept constant. But, as the upper side of  $b$  also sinks 1 inch, the pressure per square inch on it will increase by  $w$ . If now the ratio of this upper area of  $b$  to its lower area be made 7, this increase of  $w$  on the top face will cause an increase of  $7w$  on the lower face, and thus just neutralize the diminution of pressure on  $a$  due to the combined rise of the cage and fall of the lower side of  $b$ . Thus the unloaded cage will be in perfect balance, at whatever height it stands, if the areas  $b$  and  $b-d$  are given the ratio

$$\frac{b}{b-d} = \frac{b-d}{a} + 1.$$

The ratio  $b-d : a$  of the two strokes having been already chosen, this equation gives  $b$  directly. From the other two equations  $c$  and the necessary pressure  $p$  are found. This pressure  $p$  may be obtained by hydraulic pumps and an accumulator loaded to the right amount. If, however, the water from the mains is to be used, the ratio of the strokes or the size of  $a$  may be modified so as to suit the available working pressure  $p$ . If  $c$  be proportioned for the extra load at a given height, it will not be correct for all other heights, but this is of little consequence, because the extra load itself is variable from 0 upwards, so that no adjustment of  $c$  except to its maximum desired amount is possible. An excess of pressure on  $c$  above that needed for any given load has the effect simply of accelerating the speed of ascent, and this is modified roughly by partially closing the valve admitting water to  $C$ .

We have chosen this lift for description as the latest improvement in the design of hydraulic lifts. In it no water is wasted in raising or lowering the constant load.

When the hydraulic power is applied to the cage through a chain or rope passing over an overhead pulley, the hydraulic cylinder is usually laid horizontally for facility of setting and examination. Of course this arrangement involves much greater frictional resistance to the motion of the apparatus, but in it all the severely stressed parts may be in tension. There is greater security when they are so than when they are in compression. Tangye Brothers' hydraulic lift is arranged in this way.

Accidents to lifts occur in two ways. First, the suspending chain or rope may break, or, in those supported from below, the ram may break, or the cylinder or pipes enclosing the water may burst. To lessen the risk of such breakages the only method is to insist on good design in the details, good materials (which should be subjected to test before being used), and good workmanship. The connexion at both ends of the rope or chain to the load suspended from it, or the jointing of the different sections of the ram to each other and to the cage, is a point especially important. If such a breakage does actually occur, however, the cage is usually kept from falling by an automatic catch which grips it in whatever position it happens to occupy when the accident occurs. Tangye Brothers have for this purpose at each corner of the cage a toothed cam. The suspending rope sustains the cage through levers as shown in fig. 3. So long as there is a considerable pull on the rope, the levers keep the cams in the position shown. If the strain on the rope is relieved by accident to it, powerful spiral springs immediately force the cams outwards and the teeth become barred in the wooden guide-posts. A toothed rack is sometimes bolted to the vertical posts and tooth-shaped prongs are forced forward by springs to engage with the rack when the rope breaks. Similar arrangements are not placed between the top of the ram and the cage of direct-acting hydraulic lifts, but it is a mistaken idea that they are not as necessary in this case as in the other. Such appliances should be examined and tested at regular frequent intervals. They are apt to get out of working order through disuse. A double rope is a greater safeguard against accident.

In chain or rope lifts the gearing or other machinery may break, and in consequence the cage might run down with dangerous rapidity without the rope either breaking, or being wholly relieved of tension, so that the above catches may not come into action. This may be prevented by a self-acting clutch on the shaft, which prevents the wheel rotating unless the clutch is specially released. The most perfect and mechanically beautiful of the many devices that have been invented for this purpose is Weston's frictional automatic coupling. Fig. 4 shows it as applied to a hand sack-hoist. To the shaft  $a$  is keyed a ratchet wheel  $b$ . A pawl gearing in this prevents the shaft from ever rotating except in one direction. The plate  $c$  is also keyed to the shaft. The hauling rope sheave  $d$  and the winding barrel  $e$  both run loose on the shaft. Their opposing end surfaces are cut helical, so that, according to the relative angular positions of  $d$  and  $e$ , they are either jammed against each other and between  $c$  and  $b$ , or are loose and free to rotate round the shaft. On pulling the sheave  $d$  in one direction all the parts are frictionally

coupled together, and the barrel hauls up the load. The axial pressure producing friction between  $c$  and  $e$  and between  $d$  and  $b$  is greater than the load being hauled up in the ratio of the circumference of the barrel to the pitch of the helix. As there are two frictional surfaces, the whole friction is double this axial thrust multiplied by the coefficient of friction, and this friction must act at such a mean radius from the shaft as to have a moment greater than that of the load. <sup>a</sup>

If this is so for one load, it is so also for all others, as the friction is proportional to the load. To get sufficient friction for heavy loads with a diminished axial thrust, the very ingenious design shown in fig. 5 is adopted. Here the shaft  $a$  is driven by power, and is keyed to the boss  $d$  with a helix cut on one end. This helix abuts against a similar helix on the pinion  $e$ , which drives the hoisting barrel on a second shaft. The ratchet wheel  $b$  abuts against the collar  $f$  on the shaft  $a$ ;  $b$  runs loose on the shaft and is cast on the end of a hollow drum containing three disks of hard wood, P.P.P. These disks can slide axially along the interior of the drum, but are prevented from turning except along with the drum. Intervening between these wood disks are two iron disks, O, O, which may slide axially along the boss of the pinion  $e$ , but are prevented from rotating except along with this pinion. The axial pressure is transmitted from  $d$  to  $f$ , through the surfaces of the disks  $P$  and  $O$ , and, there being six pairs of surfaces between which this pressure is exerted, a very slight axial thrust produces sufficient friction at these surfaces to couple the ratchet wheel  $b$  to the pinion  $e$ . So long as this is exerted all the parts are jammed together, and the pawl engaging in  $b$  prevents the load lowering. However, the shaft  $a$  is rotated backwards, the helices disengage and the friction no longer binds  $e$  with  $b$ , so that  $e$  along with  $d$  and  $a$  can be rotated backwards and the load thus lowered. The weight of the load keeps  $e$  following  $d$  closely in its backward motion, and as soon as the operator or machine ceases to turn the shaft backwards the whole apparatus becomes once more frictionally bound together, and the ratchet wheel prevents further lowering. Fig. 6 shows another arrangement whereby the pinion  $e$  is uncoupled and allowed to lower the load by only a slight backward motion of the shaft  $a$ , it being unnecessary to rotate the shaft backwards continuously. This last is obviously the most handy arrangement, and when worked carefully is as absolutely safe as the other. This device in a modified form is used in Tangye's lifts.

Thomas & Sons, of Cardiff, have a similar patent safety shaft coupling, which, although it has a very different form, is constructed on exactly the same principle as that of fig. 4.

Steam has been used as a motive power in long cylinders similar to those in hydraulic lifts. It has the great advantage of having very little weight, so that the difference of head occasioned by the rise of the piston is practically nil. The disadvantage is that the steam rapidly condenses, and thus the load could not be held up at any desired height for a length of time, without a continual fresh supply of steam to the cylinders. It is not likely to come into general use for passenger lifts, but may be used advantageously for goods lifts and heavy cranes. (R. H. S.)

# LIGHT

**SOUND** may be defined as any effect on the sense of hearing, and in the same way **Light** may be defined as any effect on the sense of sight. This is the purely subjective use of the terms. But both terms are quite as frequently used in the objective as in the subjective sense. Thus, as Sound may be defined in terms of the motion of the air in the cavity of the external ear, mechanically affecting the tympanum, so Light may be defined by the mechanical effect produced upon the extension of the optic nerve which forms the sensitive surface of the retina.

In treating of Light it will be convenient to use the term in a sort of mixed sense, at least until we come to discuss the different theories which have been devised to account for the propagation of the agent which causes vision. Then we shall have to use the term entirely in the objective sense. On the other hand, in Physiological Optics we are concerned chiefly with the subjective sense of the term.

The present article is intended to give a general sketch of the subject of Optics, so far as it can be treated by the help of elementary mathematics, but with sufficient detail to show the connexion of its various branches, and to enable the reader who desires further information on any point to judge for himself under what heading he will find it in this work. The subject is arranged in the following order:—

Early History of Optics.  
Preliminary Statements with regard to Vision, Distinct Vision, the Colour-Sense, and the Duration of Visual Impressions.  
Sources of Light.  
General Reflexions on the Mechanism of Propagation of Light.  
Division of the Subject into Geometrical and Physical Optics.

## GEOMETRICAL OPTICS.

Rectilinear Propagation of Light in Homogeneous Media, Shadows, Camera Obscura, &c.  
Intensity of Illumination as depending on the Distance of the Source and the Obliquity of the Rays. Brightness and Intrinsic Brightness.  
Photometry.  
Velocity of Light.  
Behaviour of Light at the Colour Surface of Two Homogeneous Media.  
Plane, Spherical, and Cylindrical Mirrors. Real and Virtual Images.  
Single Refraction. Composite Nature of White Light. Refractive Index: Dispersion. Prisms; Fraunhofer's Lines. Irrationality of Dispersion. Achromatism. Lenses. Telescope, Microscope.  
Spectrum. Refraction by Cylinder. Rainbow.  
Refraction in a Non-homogeneous Medium. Hamilton's Characteristic Function. Mirage.  
Absorption, Abnormal Dispersion, Fluorescence, Phosphorescence.

## PHYSICAL OPTICS. UNULATORY THEORY.

Nature and Propagation of Waves. Huygens's Principle. Explanation of Reflexion and Single Refraction. Disproof of the Corpuscular Theory.  
Sketch of the History of the Undulatory Theory. Young's Discovery of Interference.  
Interference Bands. Spectrum formed by Grating. Measure of Wave Lengths. Loss of Semiundulation. Newton's Rings. Colours of Thin Plates and of Grooved Surfaces.  
Relation between Wave Length and Refractive Index.  
Double Refraction. Wave Surface in Iceland Spar.  
Polarization. Transverse Vibrations. Nature of Unpolarized Light.  
Plane, Circularly, and Elliptically Polarized Light. Nicol's Prism. Depolarization by Doubly-Refracting Plate. Fresnel's Rhomb.  
Doppler's Principle. Measurement of the Relative Velocity of Luminous Source and Spectator.

Under OPTICS (GEOMETRICAL, PHYSICAL, and PHYSIOLOGICAL) further developments will be given; and the

connexion between light and radiant heat will be discussed under RADIATION.

**EARLY HISTORY OF THE SUBJECT.**—It is to sight that we are mainly indebted for our knowledge of external things. All our other senses together, except under very special conditions, do not furnish us with a tithe of the information we gain by a single glance. And sight is also that one of our senses which we are able most effectively and extensively to aid by the help of proper apparatus—not merely (as by spectacles, invented *circa* 1300) for the cure of natural defects, but (as by the telescope and microscope) for the examination of bodies either too distant or too minute to be studied by the unassisted eye.

It is very remarkable, under these circumstances, to find how slowly men have reached some even of the simplest facts of optics. We can easily understand how constant experience must have forced on them the conviction that light usually moves in straight lines, *i.e.*, that we see an object in the direction in which it really lies. But how they could have believed for ages that objects are rendered visible by something projected from the eye itself—so that the organ of sight was supposed to be analogous to the tentacula of insects, and sight itself a mere species of touch—is most puzzling. They seem not till about 350 B.C. to have even raised the question:—If this is how we see, why cannot we see in the dark? or, more simply,—What is darkness? The former of these questions seems to have been first put by Aristotle.

The nature and laws of reflexion were, of course, forced on the ancients by the images seen in still water; and the geometers of the Platonic school were well acquainted with these laws. To Hero of Alexandria we owe the important deduction from them that the course of a reflected ray is the shortest possible.

The general nature of refraction also was known, with some of its special applications, such as, for instance, to burning-glasses and to magnifiers. These were probably either spherical glass shells filled with water (Pliny, *H.N.*, xxxvi. 67 [25]; Lact., *De Ira Dei*, c. 10) or balls of rock crystal (Pliny, xxxvii. 10).

In the first century of our era Cleomedes pointed out how a coin at the bottom of an empty cup, where the eye cannot see it, can be made visible by filling the cup with water; and he showed that, in a similar way, the air may render the sun visible to us while it is still under the horizon. Shortly after this date Ptolemy (the celebrated astronomer) published his great work on *Optics*. He treats of vision, reflexion, the theory of plane and concave mirrors, and refraction. He measured, with considerable accuracy, the angles of incidence and refraction, for rays passing from air into water and into glass and from water into glass; it was not, however, till more than fifteen hundred years had passed that the true relation between these angles was discovered. In addition to what has just been mentioned, the ancients' knowledge of optics was limited to a very superficial acquaintance with some of the properties of rainbows, halos, mirage, &c. But it was fragmentary in the extreme—though it far surpassed in amount as well as in accuracy their knowledge of the other branches of physical science.

It is not easy to understand the ideas of the ancients about colour. That it is a property of a body—just as its density, its hardness, or its smell is a property—was probably held by them. But they also imagined that a body could communicate its colour to light, thus, for instance, the clouds were, by some of them, supposed

to communicate their colours to the sunbeams which form a rainbow.

Our next glimpse of 'real progress dates from the 11th or 12th century, when ALHAZEN (*q.v.*)<sup>1</sup> wrote a treatise on optics in Arabic, which for five hundred years or more was a recognized authority on the subject. It was, in many parts, founded on the work of Ptolemy, but with considerable additions and improvements. Alhazen gives an anatomical description of the eye, and points out, fairly enough, how with two eyes we see only one image. But he also points out that we see each object, however small, by a *pencil* of diverging rays,—not (as the ancients imagined) by a single ray. Alhazen accounts for twilight, and shows how by it to measure the height of the atmosphere. He also gives the now generally received explanation of the curious fact that the sun and moon appear larger when rising or setting than when they are high in the heavens.

The farther progress of the subject we need not now trace. From the end of 16th century that progress has been extremely rapid. The dates of the more important steps, and the names of their authors, will be given when we treat of these, in their turn, in the course of the article; and we will give them the additional interest of being presented, when this can readily be done, in the author's own words.

Vision.

**PRELIMINARY STATEMENTS.**—Before we commence a more rigorous treatment of the subject, it may be well to make a few preliminary statements as to the nature of *vision* and the conditions for *distinct vision*. Properly speaking, these belong to OPTICS (PHYSIOLOGICAL) (*q.v.*), but it is impossible to treat intelligibly any part of our subject without presupposing some, generally very slight, knowledge of other parts. And the few preliminary statements we have now to make are in no respect theoretical, while they are so simple that any one may at once test their truth for himself.

Distance of most distinct vision.

Except in the case of a very abnormal eye (extremely short-sighted or long-sighted as the case may be) there is a distance from it—usually somewhere about 10 inches—at which if an object be placed it is seen more distinctly than if placed at any other distance. Almost every one, perhaps without knowing it, habitually places at or about that distance from his eye an object which he wishes to examine carefully. When he places it at a smaller distance he becomes conscious of the *effort* required to see it distinctly. He has, in fact, to alter the form of the optical machinery of the eye, by a muscular effort, so that it may become capable of bringing to a focus on the retina rays more divergent than those for which the parts were in their unstrained state adapted. A corresponding effort, but usually much more slight, is commonly felt to be required if the object be at a distance greater than 10 inches.

Limits of distinct vision.

Hence we arrive at the conclusion that, for the minimum of strain on the eye, rays should fall on it diverging as if they came from a point about 10 inches distant. But for all ordinary eyes any divergence from double of this (*i.e.*,

divergence as if from a distance of 5 inches) to zero (*i.e.*, parallel rays) is consistent with the possibility of distinct vision. Rays either more divergent than the former limit, or convergent, are unfit to produce distinct vision. Hence every optical instrument, whatever be the reflexions or refractions to which light has been subjected in passing through it, must finally allow the light to escape either in parallel rays or with a divergence within the above specified limits, if it is to be employed by an ordinary eye. The comparatively slight differences which exist among ordinary eyes are easily compensated by the rack-work, or screw adjustment, which is invariably attached to the eye-piece of a good telescope and to the body of a good microscope. Every motion of this rack-work alters the divergence of the rays as they finally escape from the instrument. Any eye, however abnormal, if it be capable of producing distinct vision at all, has only to be furnished with suitable spectacles in order that it may behave exactly as does a normal eye. This statement, however, refers only to sharpness of definition, not in any degree to *colour*. The deficiency which causes *colour-blindness* cannot be supplied by any conceivable process. A definite part of the ordinary organ of vision is wanting (or inactive) in such cases—while the merely optical parts of the eye are usually in perfect order.

Another fact which must be stated here is that, to produce vision of a body in its natural position, the image on the retina, as seen from the back, must be inverted—not merely as regards up and down, but also as regards right and left. Thus, in the ordinary astronomical telescope, the image on the retina is not inverted, and we therefore see an inverted image.

A third is that our judgment of the relative distances of objects is formed mainly by the use of the two eyes simultaneously. One eye, kept still, can inform us only of relative distance in virtue of the greater or less effort to see distinctly (already spoken of). With both eyes, or with one eye moved from side to side, *parallax* comes in, and gives us the *stereoscopic* effect, as it is called. This power of judging distance is, of course, greater as the eyes are set more widely apart. There is, practically, no limit to the effective distance between the eyes when the proper instrumental methods (as with the *telescope*) are employed.

It is also necessary to premise a few words about *colour*. The various homogeneous rays of the solar spectrum have each a colour of its own which no refraction can modify. But what about the many colours which do not occur in the spectrum? To such a question as "What is *yellow*?" the answer is, "Each particular kind of yellow may be any one of an infinite number of different combinations of homogeneous rays." And the same is true, in general, of all other colours. Clerk Maxwell found that a yellow equivalent to that of the spectrum can be obtained by mixing in proper proportions certain homogeneous red and green rays. This single example is sufficient to show that the colour-sense is of a very singular nature. This question will be fully treated in OPTICS (PHYSIOLOGICAL); but for our present purpose it is only necessary to say that we now know (after Wüensch and Young) that the normal eye has only *three colour-sensations*—a red, a green, and a violet,—and that the apparent colour of any light which falls on it depends merely on the *relative intensities of the excitement* produced by the light on the three organs of sense corresponding to these sensations. This is true, however, only within certain limits of intensity; for *extremely bright light*, whatever be its real colour, seems to excite all the three sensations simultaneously, much as white light does; and with very feeble light (as, for instance, that of an ordinary aurora or of a lunar rainbow) we are sometimes scarcely conscious of

<sup>1</sup> The proper name of this geometer is El-Hazn (or by other account, Mohammed) ibn el-Hasan ibn el-Haitham, and it is as Ibn el-Haitham that he is commonly referred to. See Woepeke, *L'Alphabet d'Optique d'Alhazan* (Paris, 1851), p. 7; *sq.*, and Bar Hebraeus, *Chron.* p. 221 *sq.* Several of his mathematical treatises exist in English libraries (see the Catalogues of the Br. Mus., Bodl., and India Office MSS.), but the only copy of his great optical work—the *Kitāb al-Manāẓir*—known to be in Europe is No. 1011 of the Leyden collection, with the commentary *Tuḥfat al-Manāẓir* of Kemal ed-Din Abul Hasan (*Cat. Cod. Or. Inq.*, *Bot.*, iii. 61). A smaller work (Woepeke, *l. supra*) was based on the optical treatises ascribed to Euclid and Ptolemy, and Ibn el-Haitham claims to have restored the lost first book of the latter. The Arabs had Euclid's *Optics* (*Kitāb al-Manāẓir*) in the version of Nāṣir ed-Din Tusy (*H. Kh.*, No. 10,532; *Leah. MSS. of India Office*, No. 743).

Colour blind-  
ness.

colours. In *colour-blindness* one or more of these organs of sense is wanting, or imperfect. The most common form, Daltonism, depends on the absence of the red sense. Great additions to our knowledge of this subject, if only in confirmation of results already deduced from theory, have been obtained in the last few years by Holmgren<sup>1</sup>; who has experimented on two persons, each of whom was found to have one colour-blind eye, the other being nearly normal. In this way was obtained, what could otherwise have been matter of conjecture only, a description of colour-blind vision in terms of (at least approximately) normal vision.

Duration of visual  
impressions.

Finally, the sensation of sight is not limited to the duration of the mechanical action on the eye. It is known that we do not see a sudden flash (an electric spark for instance) until a measurable, though very short, period has elapsed. This depends on the rate at which an excitation is propagated along the optic nerve. But the familiar experiment of whirling a red-hot stick in a dark room shows that the sensation of sight lasts for a short period after the mechanical action which produced it has ceased. This period is probably different for different eyes, and for different amounts of excitement even in the same eye. (If the light be very intense the effect lasts much longer, but completely change its character.) For our present purpose it may be assumed that the duration is somewhere about  $\frac{1}{10}$ th of a second. Thus, if the end of the red-hot stick describes a circle once in  $\frac{1}{10}$ th of a second, we see the complete circle; if in a longer period, we only see at once such a part of it as was described in

Intensity as de-  
pending  
on dura-  
tion of  
exciting  
cause.

$\frac{1}{10}$ th of a second. Connected with this is the remarkable result obtained experimentally by Swan,<sup>2</sup> that the amount of sensation is, for flashes of short duration, directly proportional, not only to the brightness of the flash, but also to its duration. A flash which lasts for  $\frac{1}{10}$ th of a second produces the full effect on the eye; but an electric spark, as a flash of lightning, which certainly does not endure for more than  $\frac{1}{1000000}$ th of a second, produces at most only  $\frac{1}{1000000}$ th of the effect it would produce if it lasted  $\frac{1}{10}$ th of a second. On this short duration of visual impressions depends the action of the *thaumatrope*, the *wheel of life*, &c. By various kinds of machinery a suc-

cession of views of an object in different positions or forms is presented to the eye, each for a brief interval. The result is that we fancy we see one and the same object going through a species of *continuous* motion, or of change of form, which would present it to the eye in these successive positions or forms. Thus, a tadpole may be represented as wriggling about, or as developing continuously into a frog, &c.

**SOURCES OF LIGHT.**—This subject will be fully treated in other parts of this work under various heads: from the purely scientific point of view under RADIATION; from the more practical side under LIGHTING (ELECTRIC), &c. For our present purpose a very brief summary of the question will suffice; and we do not require to investigate the *process* by which, in any case, the light is produced.

Incan-  
descence.

1. The main source of light is *incandescence*. (It is usually understood that to be incandescent a body must be at a high temperature.) This may be due to any of a number of causes, such as the following:—  
(a) *The Potential Energy of Gaseous or Scattered Fragments of Matter.*—When these fall together, as in the formation of the sun and stars, heat enough is generated by impact to render the whole vividly incandescent. It is probable that the light of nebulae, and the *proper* light of comets, is due to this cause. The proximate cause, in all these cases, is the kinetic energy of the fragments

before impact. To this class, therefore, can be reduced the light given out when a target is struck by a cannon shot.

(b) *The Kinetic Energy of Current Electricity or of an Electric Discharge.*—Here we have lightning, the electric light, and probably also the light of the aurora.

(c) *The Potential Energy of Chemical Affinity.*—The lime-light, gas-light, candle and lamp light, fire light, the magnesium light, &c.; also phosphorus, dead fish (b), &c., glowing in the dark.

(d) *Friction*, as in the trains of sparks from a grindstone or brake; though here, in general, chemical affinity also has a share.

(e) *Sudden great Compression of a Gas*, as of air by meteoric stones and falling stars.

2. Another very curious source, not (so far as is known) reducible to incandescence, is the giving out (usually in an altered form) of light previously absorbed:—fluorescence, phosphorescence, &c.

3. A third source is *physiological*: fire flies, glow-worms, *Medusa*, dead fish (f), &c., the eye of a cat.

Any not black and not transparent body, exposed to any of these sources of light, becomes in its turn what may for our purpose also be treated as a source.

As will be shown in RADIATION, the only bodies which, when incandescent, give every constituent of white light are bodies which are black in the sense of absorbing each and every ray which falls upon them. Such bodies are not necessarily solids—though the best examples we have of them are lamp black, and (somewhat less perfect) charcoal and gas coke.

Newton's speculations on these subjects, taken from the "Queries" at the end of his *Optics*, give an exceedingly interesting sketch of the state of this subject in his time. We quote a few of the more curious. There is a strange admixture of errors, but a still more strange anticipation of some of the most important of modern discoveries.

"Query 6. Do not Black bodies conceive heat more easily from light than those of other colours do, by reason that the light falling on them is not reflected out?"

"Query 7. Do not all Fixed bodies, when heated by fire, emit a certain light and shine; and is not this owing to the vibrating motions of their parts? As which abound with terrestrial parts, metals, &c., emit light, whether that agitation be made by heat, or by percussion, or by any vital motion, or by any other cause?"

"Query 8. Is not fire a body heated so copiously? For what else is a red-hot iron, or a burning coal than red-hot wood?"

"Query 9. Is not flame a vapour, made of exhalation heated red-hot, that is, so hot as to shine? For bodies do not flame without emitting a copious flame, and this flame burns in the flame. The *Flux Fabronis* is a vapour shining without heat, and is there not the same difference between this vapour and flame, as between rotted wood shining without heat and burning coals of fire? In distilling hot spirits, if the head of the still be taken off, the vapour, which ascends out of the still, will take fire at the flame of a candle, and turn into flame, and the flame will run along the vapour from the candle to the still. Some bodies heated by motion or fermentation, if the heat grow intense, flame copiously, and if the heat be great enough, the flames will shine, and become flame. Metals in fusion do not flame for want of a copious flame, except spelter, which flames copiously, and thereby flames. All flaming bodies, as oil, tallow, wax, wood, fossil coals, pitch, sulphur, by flaming water, and vanish into burning smoke, which smoke, if the flame be put out, is very thick and visible, and sometimes smells strongly, but in the flame loses its smell by burning; and, according to the nature of the smoke, the flame is of several colours; as that of sulphur, blue; that of copper opened with sublimate, green; that of tallow, yellow; that of camphire, white. Smoke passing through flame cannot but grow red-hot; and red-hot smoke can have no other appearance than that of flame."

"Query 10. Do not Great bodies conserve their heat the longest, their parts heating one another; and may not Great dense and Fixed bodies, when heated beyond a certain degree, emit light so

<sup>1</sup> *Proc. Roy. Soc.*, Jan. 1881.

<sup>2</sup> *Trans. Roy. Soc. Edin.*, 1849, 1861.

copiously, as by the emission and re-action of its light, and the reflexions and refractions of its rays within its pores, to grow still hotter, till it comes to a certain period of heat, such as is that of the sun? And are not the sun and fixed stars great earths vehemently hot; whose heat is conserved by the greatness of the bodies, and the mutual action and re-action between them, and the light which they emit; and whose parts are kept from fuming away, not only by their fixity, but also by the vast weight and density of the atmospheres incumbent upon them, and very strongly compressing them, and condensing the vapours and exhalations which arise from them? . . . And the same great weight may condense those vapours and exhalations, as soon as they shall at any time begin to ascend from the sun, and make them presently fall back again into him; and by that action increase his heat, much after the manner that in our earth the air increases the heat of a culinary fire. And the same weight may hinder the globe of the sun from being diminished, unless by the emission of light, and a very small quantity of vapours and exhalations."

Mechanism of propagation of light.

**THEORIES OF PROPAGATION OF LIGHT.**—We may begin by assuming that the sensation of light is due to a mechanical action on the retina (see EYE). Now such a mechanical action must have a mechanical cause, and, as far as we can judge with our present knowledge, the latter must consist of impacts on the retina, due to moving matter. This matter may have travelled all the way from the source of light, or it may have been set in motion in the eye by a disturbance (analogous to a wave) which has travelled from the source. What is transferred, or what moves, is a quite independent question. Light must, as far as we can conceive, consist in the motion of particles of some kind from external objects to the eye, or in the propagation of some disturbance or wave-motion in an as yet unknown medium. Though it has been proved, as we will presently show, that some of the consequences of the first supposition are entirely inconsistent with observed facts, the nature of the propagation of the supposed luminous particles is still a very interesting study, and indeed many of the fundamental propositions in optics follow more easily from this hypothesis than from the other. We will therefore *not* at present dismiss this hypothesis, but will refer freely to it now and then, until its truth is shown to be inconsistent with experiment.

Corpuscular theory.

This view, associated with the names of Newton, Laplace, and Biot, is known as the *corpuscular theory* of light. A formidable objection to it, *in limine*, will be easily seen to be furnished by the velocity of light. Since every point of every visible body must (on this theory) send such corpuscles to the eye, moving as we shall find at a rate of nearly 200,000 miles per second, their masses must be inconceivably minute in order that their united momentum may not amount to something comparable with that of a cannon shot, a supposition of course utterly destructive of all belief in the hypothesis. But, as we shall see, there are still higher grounds of objection, and such as no mere smallness of mass or size of each corpuscle can explain away.

Undulatory theory.

The rival theory labours under considerable disadvantages, inasmuch as the theory of wave-propagation is very much more obscure and difficult than that of the motion of free particles; but the student, who has mastered the fundamental difficulties of sound (see ACOUSTICS), which presents a fair although not an exact analogy, will find it comparatively easy to obtain a clear conception of the fundamental principles of the explanation offered by the *undulatory theory* of light.

The difference between these two theories of light may be illustrated by contrasting wind moving at the rate of 1100 feet per second (an inconceivably violent hurricane) and sound, gentle or violent, moving at precisely the same rate—yet how different in its effects!

**DIVISION OF THE SUBJECT.**—Optics, or the science of Light, is usually divided into two parts. A simple illustration of the nature of this division will be found in

the different conditions of fluid equilibrium according to whether we do not or do introduce the idea of action between the fluid and the containing vessel (*CAPILLARY ACTION*, q.v.). In the first or hypothetical case it is known that the free surface must be horizontal, and that all its separate parts must lie in the same plane; in the second, i.e., the actual, case we find molecular action modifying these results, sometimes indeed to a very large extent, so that no part of the free surface is plane, and no two portions of it are at the same level. So in what is called *GEOMETRICAL OPTICS* it is assumed from experiment that light moves in straight lines in air, while *PHYSICAL OPTICS*, or the undulatory theory, agrees with experiment in showing that under certain circumstances a ray of light bends round an obstacle. But as, in obtaining the main facts of fluid equilibrium, capillary forces may be neglected, so, for the explanation of the ordinary phenomena of light, even with accuracy sufficient for the construction of the very finest telescopes and microscopes, it suffices that Geometrical Optics, based on laws nearly verified by experiment, be followed out to its consequences. The residual phenomena then came in to be treated by the undulatory theory. Pouillet divides the subject, in consequence of this distinction, into two parts, viz., (1) that in which we deal with the direction only of the rays, and (2) that in which we deal with the physical properties of the rays themselves.

In this order we will consider the subject, giving the explanations of the approximate experimental laws of Geometrical Optics, as we reach them, in the language of either theory. But before we come to the residual phenomena we shall have found that the corpuscular theory must be rejected, and we will therefore give, without detail, the principles of the undulatory explanation, which will be fully discussed in a special article.

## GEOMETRICAL OPTICS.

### *Rectilinear Propagation of Light.*

It is approximately true that, in any homogeneous medium, *light moves in straight lines*.

If an opaque body be placed anywhere in the straight line between the eye and an object, the object is concealed. Through a long straight tube no objects can be seen but those situated in the direction of its axis produced. This is so fundamental a fact, or it is so evident a result of experience, that it is the foundation of every process which involves the direction in space of one object as regards another,—whether it be for the aiming with a rifle, the pointing of a telescope, or for the delicate observations of a geodetic survey. But we must carefully observe the restrictions under which the statement is made. Not only is it said to be only approximately true, but it is so only in a homogeneous medium. To both of these restrictions we will revert later.

(a) On this is founded the geometrical theory of *shadows*,—a subject of some importance, especially as regards eclipses. In this application the result may be considered as absolutely true, though, as we shall see in a subsequent page, the statement is liable in delicate cases to somewhat startling exceptions. An opaque body is placed between a screen and a light source, and casts a shadow on the screen. (The mode of attempting to realize the con- sideration of a small needle-hole in a plate of metal, and placing it close to any bright outline of the shadow straight lines.) The shadow is found by drawing straight lines from the luminous point, by piercing a very small hole in a metal, and placing it close to any bright outline of the shadow straight lines.

opaque body all round. These lines form a cone. The points of contact form a line on the opaque body separating the illuminated from the non-illuminated portion of its surface. Similarly, when these lines are produced to meet the screen, their points of intersection with it form a line which separates the illuminated from the non-illuminated parts of the screen.

This line is called the boundary of the *geometrical shadow*. A common but beautiful instance of it is seen when a very small gas-jet is burning in a ground-glass shade, near the wall of a room. In this case the cone, above mentioned, is usually a right cone with its axis vertical. Thus the boundary of the geometric shadow is a portion of a circle on the roof, but a portion of an hyperbola on the vertical wall. If the roof be not horizontal, we may obtain in this way any form of conic section. Interesting and useful hints in *projection* may be obtained by observing the shadows of bodies of various forms cast in this way by rays which virtually diverge from one point: *e.g.*, how to place a plane quadrilateral of given form so that its geometric shadow may be a square; how to place an elliptic disk, with a small hole in it, so that the shadow may be circular with a bright spot at its centre, &c.

When there are more luminous points than one, we have only to draw separately the geometrical shadows due to each of the sources, and then superpose them. A new consideration now comes in. There will be, in general, portions of all the separate geometrical shadows which overlap one another in some particular regions of the screen. In such regions we still have full shadow; but around them there will be other regions, some illuminated by one of the sources alone, some by two, &c., until finally we come to the parts of the screen which are illuminated directly by all the sources. There will evidently be still a definite boundary of the parts wholly unilluminated, *i.e.*, the true shadow or *umbra*, and also a definite boundary of the parts wholly illuminated. The region between these boundaries—*i.e.*, the partially illumined portion—is called the *penumbra*.

Fig. 1 shows these things very well. It represents the shadow of a circular disk cast by four equal luminous

is obvious that the degrees of darkness at different portions of the penumbra will also increase indefinitely; *i.e.*, there will be a gradual increase of brightness in the penumbra from total darkness at the edge next the geometrical shadow to full illumination at the outer edge. It is most instructive to contrast with the above figure that now given (fig. 2), in which the size of the disk is considerably diminished—everything else being unchanged. Here there is no true shadow—only four equally bright portions of the penumbra, each illuminated by three of the sources.

Fig. 2.

Thus we see at once why the shadows cast by the sun or moon are in general so much less sharp than those cast by the electric light (when it is not surrounded by a semi-opaque screen). For, practically, at moderate distances from the electric arc, it appears as a mere luminous point. But, if we place a body at a distance of a foot or two only from the arc, the shadow cast will have as much of penumbra as if the sun had been the source. The breadth of the penumbra when the source and screen are nearly equidistant from the opaque body is equal to the diameter of the luminous source. Simple as is the question from the point of view we have adopted, it may to some persons appear simpler to imagine themselves placed (as spectators) on the screen in different parts of the shadow or penumbra, and to consider what portions of the luminous source they would then be in a position to see.

This is what happens to us when we observe an eclipse of the sun. When the eclipse is total, there is a real geometrical shadow,—very small compared with the penumbra (for the *apparent* diameters of the sun and moon are nearly equal, but their distances are as 370 : 1); when the eclipse is annular, the shadow is all penumbra. In a lunar eclipse, on the other hand, the earth is the shadow-casting body, and the moon is the screen, and we observe things according to our first point of view.

Suppose, next, that the body which casts the shadow is a large one, such as a wall, with a hole in it. If we were to plug the hole, the whole screen would be in geometrical shadow. Hence the illumination of the screen by the light passing through the hole is precisely what would be cut off by a disk which fits the hole. Fig. 3, which is the

Fig. 1.

points arranged at the corners of a square,—the disk being large enough to admit of a free overlapping of the separate shadows. The amount of want of illumination in each portion of the penumbra is roughly indicated by the shading. The separate shadows are circular, if the disk is parallel to the screen. If we suppose the number of sources to increase indefinitely, so as finally to give the appearance of a luminous surface as the source of light, it

Fig. 3.

shadow. Hence the illumination of the screen by the light passing through the hole is precisely what would be cut off by a disk which fits the hole. Fig. 3, which is the

complement of fig. 1, gives therefore the effect of four equal sources of light shining on a wall through a circular hole. And it is evident that, with the change of a word here and there, the previous reasoning may be applied to this case also. The umbra in the former case becomes the fully illuminated portion, and *vice versa*. The penumbra remains the penumbra, but it is now darkest where before it was brightest, and *vice versa*. For further information we subjoin the complement (fig. 4) of the second case above, the same four sources, but the smaller hole. Here we have four

Fig. 4.

Images  
by small  
hole.

equally bright, separate images—one belonging to each of the sources. Thus we see how, when a small hole is cut in the window-shutter of a dark room, a picture of the sun, and bright clouds about it, is formed on the opposite wall. This picture is usually inverted, and also perverted, for not only are objects depicted lower the higher they are, but also objects seen to the right are depicted to the left, &c. But it will be seen unperverted (though still inverted) if it be received on a sheet of ground glass and looked at from behind. The smaller the hole (so far at least as Geometrical Optics is concerned) the less confused will the picture be. As the hole is made larger the illuminated portions from different sources gradually overlap; and when the hole becomes a window we have no indications of such a picture except from a body (like the sun) much brighter than the other external objects. Here the picture has ceased to be one of the sun, it is now a picture of the window. But if the wall could be placed 100 miles off, the picture would be one of the sun. To prevent this overlapping of images, and yet to admit a good deal of light, is one main object of the lens which usually forms part of the camera obscura.

Shadow  
image.

The formation of pictures of the sun in this way is well seen on a calm sunny day under trees, where the sunlight penetrating through small chinks forms elliptic spots on the ground. During a partial eclipse these pictures have, of course, a crescent form. When detached clouds are drifting rapidly across the sun, we often see the shadows of the bars of the window on the walls or floor suddenly shifted by an inch or two, and for a moment very much more sharply defined. They are, in fact, shadows cast by a small portion of the sun's limb, from opposite sides alternately. Another beautiful illustration is easily obtained by cutting with a sharp knife a very small T aperture in a piece of note paper. Place this close to the eye, and an inch or so behind it place another piece of paper with a fine needle hole in it. The light of the sky passing through the needle hole forms a bright picture of the T on the retina. The eye perceives this picture, which gives the impression of the T much magnified, but turned upside down.

Phanton.  
pali-  
sades.

Another curious phenomenon may fitly be referred to in this connexion, viz., the *phantoms* which are seen when we look at two parallel sets of palisades or railings, one behind the other, or look through two parallel sides of a meat-safe formed of perforated zinc. The appearance presented is that of a magnified set of bars or apertures which appear to move rapidly as we slowly walk past. Their origin is the fact that where the bars appear nearly to coincide the apparent gaps bear the greatest ratio to the dark spaces; i.e., these parts of the field are the most highly illuminated. The exact determination of the appearances in any given case is a mere problem of convergents to a continued fraction. But the fact that the

apparent rapidity of motion of this phantom may exceed in any ratio that of the spectator is of importance,—enabling us to see how velocities, apparently of impossible magnitude, may be accounted for by the mere running along of the condition of visibility among a group of objects no one of which is moving at an extravagant rate.

(b) Another important consequence of this law is that *if the medium be transparent the intensity of illumination which a luminous point can produce on a white surface directly exposed to it is inversely as the square of the distance.*

The word transparent implies that no light is absorbed or stopped. Whatever, therefore, leaves the source of light must in succession pass through each of a series of spherical surfaces described round the source as centre. The same amount of light falls perpendicularly on all these surfaces in succession. The amount received in a given time by a unit of surface on each is therefore inversely as the number of such units in each. But the surfaces of spheres are as the squares of their radii,—whence the proposition. (We assume here that the velocity of light is constant in the medium, and that the source gives out its light uniformly and not by fits and starts.) When the rays fall otherwise than perpendicularly on the surface, the illumination produced is proportional to the cosine of the obliquity; for the area seen under a given spherical angle increases as the secant of the obliquity, the distance remaining the same.

As a corollary to this we have the further proposition *Bright-ness at different distances,* that the apparent brightness of a luminous surface (seen through a transparent homogeneous medium) is the same at all distances.

The word brightness is here taken as a measure of the amount of light falling on the pupil per unit of spherical angle subtended by the luminous surface. The spherical angle subtended by any small surface whose plane is at right angles to the line of sight is inversely as the square of the distance. So also is the light received from it. Hence the brightness is the same at all distances.

The word brightness is often used (even scientifically) in another sense from that just defined. Thus we speak of a bright star, of the question—When is Venus at its brightest? &c. Strictly, such expressions are not defensible except for sources of light which (like a star) have no apparent surface, so that we cannot tell from what amount of spherical angle their light appears to come. In that case the spherical angle is, for want of knowledge, assumed to be the same for all, and therefore the brightness of each is now estimated in terms of the whole quantity of light we receive from it. It is in this sense *Maximum brightness of Venus,* only that we use the word when we speak of Venus at its brightest; for if we take the former definition of brightness the solution of this once celebrated problem would be very different from that usually given. As the question, however, is an interesting one both in itself and historically, we give an approximate solution of it. The approximation assumes what is certainly not true, that the illuminated portion of Venus always appears uniformly bright, and of the same degree of brightness in all aspects.

Let  $a$  be the radius of the earth's orbit,  $b$  that of the orbit of Venus,  $\delta$  the distance between the planets when Venus is brightest. Then if  $\theta$  be the apparent angular distance of the earth from the sun as seen from Venus, the illuminated part of the disk of Venus as seen from the earth is

$$\frac{1 + \cos \theta}{2}$$

of the whole disk. Hence

$$\frac{1 + \cos \theta}{2^{\frac{1}{2}}}$$

is a maximum,—with the obvious trigonometrical relation  $a^2 = \delta^2 + b^2 - 2\delta b \cos \theta$ .

Substituting for  $\cos \theta$ , and putting the differential coefficient  $\sim 0$ , we have a quadratic equation of which the only admissible root is the positive one

$$\delta = \sqrt{3a^2 + b^2} - 2b.$$

From this the other quantities can be calculated.

But another matter has to be taken into consideration when we apply the above definition of brightness in practice. For the aperture of the pupil is usually very much contracted when we look at a brightly illuminated sky or cloud. Thus there is a rough compensation which, to a certain extent, modifies the effect on the retina.

Founded on the above is Chéseaux's celebrated argument about the finite dimensions of the stellar universe. For it is easy to see, as below, that if stars be scattered through infinite space, with average closeness and brightness such as is presented by those nearest us, and if stellar space be absolutely transparent, the whole sky should appear of a brightness like that of the sun. Chéseaux and Olbers endeavoured to show that, because the sky is not all over as bright as the sun, there is absorption of light in stellar space. This idea was ingeniously developed by Struve.

Consider a small spherical angle  $\omega$ . The number of stars included in it whose distances are between  $r$  and  $r + \delta r$  from the earth is proportional to

The whole amount of light received in such a portion of the sky must be therefore as

$$\omega \int_0^{\infty} \frac{dr}{r^2},$$

provided that no star intercepts the light coming from another. This condition is unattainable, so that the conclusion is that the brightness is as great as it can be with the materials employed. Every portion of the background shines as if it were a star.

(c) A third very important fact, connected with our present subject, but not immediately deducible from our principle, is—*The brightness of a self-luminous surface does not depend upon its inclination to the line of sight.*

Thus a red-hot ball of iron, free from scales of oxide, &c., appears flat in the dark; so, also, the sun, seen through mist, appears as a flat disk. This fact, however, depends ultimately upon the second law of thermodynamics, and its explanation will be fully given under RADIATION.

It may be stated, however, in another form, in which its connexion with what precedes is more obvious.—*The amount of radiation, in any direction, from a luminous surface is proportional to the cosine of the obliquity.*

The flow of light (if we may so call it) in straight lines from the luminous point, with constant velocity, leads as we have seen to the expression  $\frac{\mu}{r^2}$  (where  $r$  is the distance from the luminous point)

for the quantity of light which passes through unit of surface perpendicular to the ray in unit of time,  $\mu$  being a quantity denoting the rate at which light is emitted by the source. This represents the illumination of the surface on which it falls. The flow through unit of surface whose normal is inclined at an angle  $\theta$  to the ray is of course

$$\frac{\mu}{r^2} \cos \theta,$$

again representing the illumination. These are precisely the expressions for the gravitation force exerted by a particle of mass  $\mu$  on a unit of matter at distance  $r$ , and for its resolved part in a given direction. Hence we may employ an expression

$$\iint \frac{dV}{du} dS,$$

taken over the whole surface, has the value

$$-4\pi\mu_0,$$

where  $\mu_0$  is the sum of the values of  $\mu$  for each source lying within the surface, follows almost intuitively from the mere consideration of what it means as regards light. For every source external to the closed surface sends in light which goes out again. But the light from an internal source goes wholly out; and the amount per second from each unit source is  $4\pi$ , the total area of the unit sphere surrounding the source.

It is well to observe, however, that the analogy is not quite complete. To make it so, all the sources must lie on the same side of the surface whose illumination we are dealing with. This is due to the fact that, in order that a surface may be illuminated at all, it must be capable of scattering light, i.e., it must be to some extent opaque. Hence the illumination depends mainly upon those sources which are on the same side as that from which it is regarded.<sup>1</sup>

Though this process bears some resemblance to the heat analogy employed by Sir W. Thomson for investigations in statical electricity (*Cambridge Mathematical Journal*, 1842; and to Clerk Maxwell's device of an incompressible fluid without mass (*Cam. Phil. Trans.*, 1866, it is by no means identical with them. Each method deals with a substance, real or imaginary, which flows in certain streams from a source so that the same amount of it passes per second through every section of the cone. But in the present process the velocity is constant and the density variable, while in the others the density is variably constant and the velocity variable. There is a common property between them, which we have just given. For instance, it is easily seen that the light received from a uniformly illuminated surface is represented by

$$\iint \frac{\mu \cos \theta}{r^2} dS$$

As we have seen that this integral vanishes for a closed surface which has no source inside it, it is the same for all shells of equal uniform brightness whose edges lie on the same cone.

We have said that light moves in straight lines in a homogeneous medium. This rectilinear path follows at once from the corpuscular theory, as well as from the undulatory theory of light: in the first case there is no deflecting cause, so each corpuscle moves in a straight line; in the second, the direction of propagation of a plane wave in an uniform isotropic medium is always perpendicular to its front. Looking along a hot poker or the boiler of a steamboat, we see objects beyond distorted; i.e., we no longer see each point in its true direction. Here we have a non-homogeneous medium, the air being irregularly expanded in the neighbourhood of the hot body. To this simple cause are due the phenomena of mirage, the fata morgana, the reduplication of images of a distant object seen through an irregularly heated atmosphere, the scintillation or twinkling of stars, and the uselessness of even the best telescopes at certain times, &c. It is interesting to note here that Newton<sup>2</sup> says, "Long telescopes may cause objects to appear brighter and larger than short ones can do; but they cannot be so formed as to take away that confusion of the rays which arises from the tremors of the atmosphere. The only remedy is a most serene and quiet air, such as may perhaps be found on the tops of the highest mountains, above the grosser clouds."

PHOTOMETRY.—The principle above explained suggests many simple methods of comparing the amounts of light given by different sources. If, for instance, a porcelain plate, or even a sheet of paper, of uniform thickness, have one half illuminated directly by one source of light, the other by a different source, and if one or other of these sources be moved to or from the plate till the halves appear equally illuminated, it is obvious that the amounts of light given out by the two sources are directly as the squares of their distances from the screen. This is the principle of Ritchie's photometer. Rumford suggested the comparison of the intensity of the shadows of the same object thrown side by side on a screen by the two lights to be compared. In this case the shadow due to one source is

<sup>1</sup> From the formula of which the proof has been made Green's theorem and its consequences follow immediately. But we need not give these here.

<sup>2</sup> *Optics*, end of part I.

Ritchie's, Rumford's.

lit up by the other alone; and here again the amounts of light given out by the sources are as the squares of their distances from the screen when the shadows are equally intense. The shadow-casting object should near the screen, so as to avoid penumbra as much as possible; yet not too near, so that the shadows may not overlap.

**Bunsen's photometer.** Bunsen has recently suggested the very simple expedient of making a grease-spot on white paper for photometric purposes. When the paper is equally illuminated from both sides, the grease spot cannot be seen except by very close inspection. In using this photometer, the sources are placed in one line with the grease-spot, which lies between them and can be moved towards one or other. To make the most accurate determinations with this arrangement the adjustment should first be made from the side on which one source lies, then the screen turned round and the adjustment made from the side of the other source,—in both cases, therefore, from the same side of the paper screen. Take the mean of these positions (which are usually very close together), and the amounts of light are as the squares of the distances of the sources from this point.

**Wheatstone's.** Wheatstone suggested a hollow glass bead, silvered internally, and made to describe very rapidly a closed path, for use as a photometer. When it is placed between two sources, we see two *parallel* curves of reflected light, one due to each source. Make these, by trial, equally bright; and the amounts of light from the sources are, again, as the squares of the distances. These simple forms of apparatus give results which are fairly accurate, so long at least as the *qualities* of the light furnished by the two sources are nearly the same. But, when we endeavour to compare differently coloured lights, the result is by no means so satisfactory. In fact, we cannot well define equality of illumination when the lights are of different qualities. In the undulatory theory, no doubt, we can distinctly define the intensity of any form of radiation.

**Difficulties of photometry.** But the definition is a purely dynamical one, and has not necessarily any connexion with what we usually mean by intensity, viz., the amount of effect produced upon the nerves of the retina. Thus the theoretical intensities of a given violet and a given red source may be equal, while one may appear to the eye very much brighter than the other. Think, for instance, of a colour-blind person, who might, under conceivable circumstances, be unable to see the red at all. We are *all* as it were colour-blind as far as regards radiations whose wave-lengths are longer or shorter than those included in the range of the ordinary solar spectrum.

**Chemical photometry.** Other modes of measuring the intensity of light usually depend upon more recondite physical principles,—such as, for instance, the amounts of chemical action of certain kinds which can be produced by an exposure of a given duration to the light from a particular source. But all have the same grand defect as the simpler processes, they are not adapted to the comparison of sources giving different qualities of light. And the last mentioned are liable to another source of error, viz., the action of radiations which are not called light, only because they are not visible to the eye; for in all other respects they closely resemble light, and are often more active than it is in producing chemical change.

**Velocity of light.** VELOCITY OF LIGHT. Light moves with a velocity of nearly 186,000 miles per second. Of this we have four distinct kinds of proof, on each of which depends a method which is capable of giving pretty accurate results.

**Römer's method.** 1. *Römer's Method.*—By this the finite velocity of light was discovered in 1676. Suppose, to illustrate this, that at a certain place a cannon is fired precisely at intervals of an hour while the weather is perfectly calm. A person

provided with an accurate watch travels about in the surrounding district. When he first hears the cannon let him note the time by his watch, then on account of the non-instantaneous propagation of sound, if at the next discharge he be *nearer* the gun than before, the report will arrive at his ear *before* the hour's interval has elapsed; if he be farther from the gun, the interval between the discharges will appear longer than an hour; and the number of seconds of defect or excess will evidently represent the time employed by sound in travelling over a space equal to the difference of his distances from the gun at the successive observations.

Now the satellites of Jupiter are subject—like our moon, only much more frequently—to eclipse, and the interval between two successive eclipses can easily be observed. The almost sudden extinction of the light is a phenomenon similar to the discharge of the gun; and, if light take time to move from one place to another, we should find the interval between successive eclipses too short when we are approaching Jupiter, too long when we are receding from him. Such was found to be the case by Römer; and he also found that the shortening or lengthening of the interval depended upon the rate at which the earth was approaching to or receding from Jupiter. The inevitable conclusion from these facts is that light is propagated with finite velocity. Römer calculated from them that light takes about 16 $\frac{3}{5}$  to cross the earth's orbit. The exact velocity deduced by this method is, after making all corrections, and assuming the most probable value of the solar parallax, about 186,500 miles per second.

2. *Bradley's Method.* This depends on the aberration of **Bradley's method** light, discovered by Bradley in 1728. When in a calm rainy day one stands still he holds his umbrella vertical in order to protect himself. If he walk he requires to hold it forwards, and more inclined the faster he walks. In other words, to a person walking the rain does not appear to come in the same direction as to a person standing still. Now the earth's velocity in its orbit is a very large quantity, some 18 $\frac{1}{2}$  miles per second, or about  $\frac{1}{10000}$ th of that of light. Hence the light from a star does not appear to come in the proper direction unless the earth be moving exactly to or from the star, and, as the direction of the earth's motion is continually changing, so the directions in which different stars are seen are always changing, and thus this phenomenon, called the "aberration of light" proves at once the finite velocity of light and the earth's motion round the sun.

As an additional illustration of the phenomenon, suppose a bullet fired through a railway carriage, in a direction perpendicular to the sides of the carriage. If the carriage be standing still, the bullet will make holes in the sides the line joining which is perpendicular to the length of the carriage; if it be in motion, then the second side of the carriage will have moved through a certain space during the interval occupied by the bullet in passing from side to side, and thus the line joining the holes in the sides (i.e., the line pursued by the bullet relatively to the carriage), will be inclined at an angle greater than a right angle to the direction of the train's motion.

It is evident that the path apparently described by each star during a year, in consequence of aberration, will be found by laying off from the star lines which bear the same ratio to the star's distance as the velocity of the earth does to that of light,—their directions being always the same as that of the earth's motion at every instant. This is precisely the definition of the *Hippograph* (q.v.) of the earth's orbit. Hence, on account of the finite velocity of

<sup>1</sup> In fact, to estimate the relative direction and velocity of two moving bodies we must subtract the vector velocity of the first from that of the second.

light, each star appears to describe in space a circle (not an ellipse) of fixed magnitude in a plane parallel to that of the ecliptic. As seen from the earth, therefore, stars will appear to describe paths which are the projections of these circles on the celestial sphere. These are in general ellipses, but circles for stars at the poles of the ecliptic and straight lines for stars in the ecliptic. This is found to be quite consistent with observation; and the major axes of these ellipses, the diameters of the circles, or the lengths of the lines subtend equally angles of about  $41''$  at the earth. Hence the velocity of light is to the velocity of the earth as  $1 : \tan \frac{1}{2} 41''$ ; that is, about 10,000 : 1.

Both these methods depend, for their final result, upon a true knowledge of the earth's distance from the sun. But the most accurate measurements of this quantity are probably to be obtained from the velocity of light itself, this being independently determined by the physical processes next to be described. Thus the earth's distance from the sun will in future be measured rather by the constant of aberration, or by the acceleration or retardation of the eclipses of Jupiter's satellites, than by a transit of Venus, by the moon's motion, or by the parallax of Mars. Thus Römer's and Bradley's processes are now applied to the determination of solar parallax.

3. *Fizeau's Direct Measurement of the Velocity of Light.*—To illustrate the next and by far the most convincing popular proof of the finite velocity of light, suppose a person looking at himself in a mirror, before which is moving a screen with a number of apertures, the breadth of each aperture being equal to the distance between any two of them. If the screen be at rest with an aperture before the mirror, the light from the observer's face passes through the aperture and is reflected back, so that he sees himself as if the screen were not present. Suppose the screen to be moving in such a way that, when the light which passed through the aperture returns to the screen after reflexion, the unpierced part of the screen is in its way, it is evident that the observer cannot see himself in the mirror. If the screen pass twice as fast, the light that escaped by one aperture will, after reflexion, return by the next, so that he will see his image as at first. If three times as fast, the second unpierced part of the screen will stop the returning light; so he cannot see his image. To apply this practically a thin metallic disk had a set of teeth at its circumference so that the breadth of a tooth was equal to that of the space between two teeth. This disk could be set in very rapid rotation by a train of wheels, and the rate of turning could easily be determined by Savart's method (see *ACOUSTICS*, vol. i. p. 108). Light passed between two teeth to a mirror situated at 10 miles' distance, which sent it back by the same course, so that when the wheel was at rest the reflected light could be seen. On turning the disk with accelerated velocity the light was observed to become more and more feeble up to a certain velocity, at which it was extinguished; turning faster it reappeared, growing brighter and brighter till the velocity was doubled; then it fell off, till it vanished when the velocity was trebled, and so on. It is evident from the first illustration above that the velocity of light in air is to that of the tooth, at the first disappearance of the reflected light, as the distance of the mirror from the disk

to the details of this remarkable experiment. On the contrary, telescopes were used at each station to prevent the loss of light as much as possible, and many other precautions were adopted which would be unintelligible without reference to later parts of this article. This method and its first results were published in 1849 in the *Comptes Rendus*. The experiments gave, on their very careful repetition by

Cornu in 1874, the value 18 in vacuo (*Nature*, xi. p. 274).

4. *Foucault's Method.*—This was described in 1850 to Foucault by the Academy of Science. It depends upon the principle of the rapidly revolving plane mirror introduced by Wheatstone to demonstrate the non-instantaneous propagation of an electric discharge. The mirror was made to revolve from 600 to 800 times per second, by means of a *siren* (see *ACOUSTICS*) driven by steam. A ray of sunlight fell upon it from a small aperture crossed by a grating of platinum wires. Between the wires and the mirror was placed an achromatic lens—the wires being farther from it than its principal focus, but *not twice as far*—so that the rays falling on the mirror were slowly convergent. They formed an image of the wires at a distance of about 4 metres from the mirror. In certain positions of the revolving mirror, the rays fell upon a concave mirror of 4 metres radius whose centre of curvature was at the centre of the revolving mirror. They were, therefore, reflected back directly to the revolving mirror, and, passing again through the lens, formed an image of the wire grating which, when the adjustment was perfect, coincided with the grating itself. This coincidence was observed by reflexion from a piece of unsilvered glass, placed obliquely in the track of the rays, the image in which was magnified by an eye-piece. It is obvious that, when the mirror is made to turn, the light which comes back to it after passing to the fixed mirror, finds it in a position slightly different from that in which it left it. That difference is due to the amount of rotation during the time of passage of the light to and fro along an air-space of 4 metres. Accordingly, as soon as the mirror began to rotate with considerable velocity, the coincidence between the wires and their images was destroyed, and the two were separated more and more widely as the velocity of rotation was increased. It was easy to calculate, from the measured dimensions of the apparatus, the amount of deflexion, and the rate of rotation of the mirror—the velocity of light. The rate of rotation was, of course, given by the pitch of the note produced by the siren.

Foucault's early results with this apparatus showed that the velocity of light which had been deduced from the old methods was too large; and he concludes his first paper by the statement that the determination of the distance of the earth from the sun must now be made by physical instead of astronomical methods. Foucault's process has recently been very considerably improved by Michelson, who, in 1879, found for the velocity of light in vacuo 186,380 miles per second (*Nature*, vol. x. p. 226).

By interposing a tube filled with water and having flat glass ends, between the two revolving mirrors, Foucault found that (for the same rate of rotation) the displacement of the image was greater than before in the proportion of the refractive index of water to unity. Thus it was at once evident, by a mode of experimenting exposed to no possible doubt, that light moves faster in air than in water, and, therefore, as will be seen later, that the corpuscular theory of light must be abandoned.

Other methods of determining the velocity of light in air, and for comparing the velocities of light in air and water (on which depends the most definite proof of the erroneousness of the corpuscular theory), and in still and moving water, will be afterwards explained. They give results of very great value, but we cannot introduce them here, as they depend upon somewhat more recondite principles of physical optics.

It is interesting to observe that, as the nearest fixed star is probably about 200,000 times farther from us than the sun is, we now see such a star by light which left it more than three years ago. If, as is now supposed, *variable stars*

Time of passage of light from the nearest stars.

(such as Mira Ceti) owe their rapid periodical changes of brightness to eclipses, and if different homogeneous rays travel with different velocities in free space, it is evident that such stars would show a gradual change of colour as they wax, and an opposite change as they wane. Nothing of the kind has as yet been observed, though it has been carefully sought for. Hence we have every reason to conclude that, in free space, all kinds of light have the same velocity. It will be seen later that *dispersion* has been accounted for by the different velocities of light of different wave-lengths in the same refracting medium,—this being a consequence of the ultimate *finest* structure of ordinary matter, which is on a scale not incomparably smaller than the average wave-length.

#### Behaviour of Light at the Common Surface of Two Homogeneous Media.

When a ray of light, moving in one homogeneous medium, falls on the bounding surface of another homogeneous medium, it is in general divided into several parts, which pursue different courses. These parts are respectively (a) reflected; (β) refracted (singly or doubly); (γ) scattered; (δ) absorbed.

In the first two categories the result is two or three rays of light pursuing definite paths according to laws presently to be given. The fraction of the incident light which is reflected is in general greater as the angle of incidence is greater. In one important class of cases the reflexion is *total*. But at direct incidence the reflected portion is much greater for some bodies, such as mercury, than for others, such as water or glass. In bodies which give no scattering, the refracted portion of a ray consists of all the non-reflected portion, and therefore usually diminishes as the angle of incidence increases.

In the third category the common surface of the two media becomes illuminated, and behaves as if it were itself a source of light, sending rays in all directions. It may be objected to this, that in many cases the rays are scattered while penetrating the second medium. But in such cases the second medium cannot be called *homogeneous*. This will come up for discussion when we treat of absorption and colours.

In the fourth category the light ceases for an instant to exist as light; but its energy may either become heat in the absorbing body, or it may again be given out by the absorbing body in the form of light, but of a *degraded* character. This is called *fluorescence*, or *phosphorescence*, according as the phenomenon is practically instantaneous or lasts for a measurable time.

In category (a) the light is sent back into the first medium; in (β) it penetrates into the second; in (γ) it goes, in general, mainly to the first; in (δ) it is shared by both.

It is by scattered light that non-luminous objects are, in general, made visible. Contrast, for instance, the effects when a ray of sunlight in a dark room falls upon a piece of polished silver, and when it falls on a piece of chalk. Unless there be dust or scratches on the silver you cannot see it, because no light is given from it to surrounding bodies except in one definite direction, into which (practically) the whole ray of sunlight is diverted. But the chalk sends light to *all* surrounding bodies from which any part of its illuminated side can be seen; and there is no special direction in which it sends a much more powerful ray than in others. It is probable that if we could, with sufficient closeness, examine the surface of the chalk, we should find its behaviour to be of the nature of reflexion, but reflexion due to little mirrors inclined in all conceivable aspects, and at all conceivable angles, to the incident light. Thus scattering may be looked upon as ultimately due to

reflexion. When the sea is perfectly calm, we see in it one intolerably bright image of the sun only. But when it is continuously covered with slight ripples, the definite image is broken up, and we have a large surface of the water shining by what is virtually scattered light,—though it is really made up of parts each of which is as truly reflected as it was when the surface was flat.

We have spoken above of the behaviour of light at the common surface of two media. Now we do not by this phrase necessarily mean two media different in their chemical composition. We mean merely media *optically* different. Thus water with steam above it, and in very special cases layers of water or air of different temperatures, give surfaces of separation at which reflexion and refraction may and do take place. But, except in such special cases, we rarely have an abrupt change, such as is necessary for reflexion, between two portions of the same substance in the same molecular state. In general the transition is gradual; and special mathematical methods must be applied for the purpose of tracing the behaviour of the ray, which is now really travelling in a *non-homogeneous* medium.

REFLEXION OF LIGHT.—If light be reflected from a plane surface bounding two dissimilar isotropic media, the incident and reflected rays are in one plane with, and are equally inclined (on opposite sides) to, the perpendicular to the reflecting surface at the point of incidence. This is sometimes stated in the form—*The angles of incidence and of reflexion are equal to one another, and in one plane.* The best experimental proof of the truth of this statement is deduced from the use of a reflecting surface of mercury in observations with the mural circle. The graduation of such an instrument is the most perfect that human skill can accomplish, and no one has ever been able to find by it the slightest exception to the preceding statement.

The principle of Hadley's quadrant, and of the sextant as now used (an invention of Newton's), is founded on this fact. If a plane mirror on which a ray falls be turned through any angle about an axis perpendicular to the plane of reflexion, the reflected ray is turned through twice that angle. This is an immediate consequence of the above law. For, if the plane be turned through any angle  $\theta$ , the perpendicular to it is turned through the same angle. Hence the angle between the incident ray and the perpendicular is increased or diminished by  $\theta$ , and therefore that between the incident and reflected rays (which is double of this) is altered by  $2\theta$ . A plane mirror is now extensively used for the purpose of indicating, by the change of direction of a reflected ray, the motion of a portion of an instrument to which the mirror is attached. Thus the magnetometers of Gauss, the tuning-forks of Lissajoux, and the electrometers and galvanometers of Sir W. Thomson are all furnished with mirrors. The law of reflexion is also the basis of the goniometer, for the measurement of the angles of crystals and prisms.

It follows from this law that, if a ray pass from one point to another, after any number of reflexions at fixed surfaces, the length of its whole path from one point to the other is the least possible—subject to the condition that it shall *meet* each of the reflecting surfaces. For the point in a given plane the sum of whose distances from two given points (on the same side of the plane) is the least possible is that to which, if lines be drawn from the points, they are in one plane with the normal (or perpendicular) to the given plane and make equal angles with it. And, as the same is true of each separate reflexion, it is true for the whole course of the ray, since for any one of the reflecting surfaces may be substituted its tangent plane at the point of incidence.

Gradual transition from one medium to another.

Reflexion of light.

Visibility of non-luminous objects.

Minimum length of path.

It is to be remarked that there are exceptions to this form of the statement. The true form is that the actual path of a ray, under the given conditions, is less in length than any other path (satisfying the conditions) which is nowhere finitely divergent from it. This may be best seen by another method. Suppose a series of ellipses to be described whose foci are the source of light and an assigned point which is to be reached by the reflected ray. Let this system turn about the line joining the foci; it generates a series of prolate spheroids such that the time of light's passing from one focus to a point in any one of the surfaces, and thence to the other focus, is the same whatever point be chosen on that particular surface. If we take any point *without* that surface, for it the corresponding time is obviously greater. Hence to find the path of that one of a system of rays diverging from a given point which, after reflexion at a given surface, shall pass through a given point, we have only to imagine spheroids constructed as before. Of these one at least will *touch* the given surface. All points on the surface in the neighbourhood of the point of contact (mark this limitation) will in general lie outside the spheroid. Hence this point gives the shortest path. But the spheroid and the reflecting surface have the same tangent plane, and therefore the parts of the ray are equally inclined to the surface.

Images  
by re-  
flexion.

**Formation of Images by Reflexion at a Plane Surface.**—We may assume here—what is in fact evident from the rectilinear propagation of light—that objects are rendered visible to the eye by rays *diverging* from them. Hence, if we have a set of reflected or refracted rays diverging from any point, or diverging as if they came from any point, they will convey to the eye the impression of the existence of a luminous source at that point. The eye, in fact, can only tell us what effect is produced upon it, *i.e.*, what sort of mechanical action it is subjected to. Its indications must therefore depend only upon what reaches it, and in no other sense whatever upon the source or the path of light. This point from which rays diverge—or *appear* to diverge, is called an *image*.

The image of any point in a plane mirror is found by drawing from the point a perpendicular to the mirror and producing it till its length is doubled.

Real and  
virtual  
images.

The extremity of the line so drawn is the image of the point; or, in other words, rays proceeding from the point diverge after reflexion as if they came from the image so found. The image in this case is called *virtual*, to distinguish it from cases, subsequently to be mentioned, where it is *real*—the distinction being that the rays have actually passed through a real image, while they only appear to come from a virtual one.

To prove this it is only necessary to observe that, if A (fig. 5) be a luminous point or a point from which rays

Fig. 5.

diverge, and CB any section of the mirror by a plane through AB, the perpendicular to it, and if we make  $Ba = AB$ , and take any point P, then, joining AP,  $aP$ , and producing the latter, the angles APB,  $aPB$ , and therefore CPQ are equal; also the plane of the paper contains the perpendicular to the mirror at P. Hence PQ is the reflected ray; or the ray, after reflexion, appears

to come from *a*. Hence *a* is the image—a virtual one, as before noticed. Also, if R be any point whatever (not P) in the plane of the mirror, we have obviously  $aR = RA$ . Hence the path AR, RQ is equal to  $aR$ , RQ, two sides of the triangle  $aRQ$ , of which  $aQ$ , which is equal to the actual path (AP, PQ), is the third side.

Fig. 6 represents the pencils of diverging rays by which two points of the image are rendered visible to an eye placed in front—

of the mirror. From the requisite modification of this figure it follows that one can see his whole person in a mirror of only half his height and breadth.

Dircks's *ghost*, which has played a prominent part in popular entertainments for some years back, is the image, in a large sheet of unsilvered plate glass hung at the front of the stage, of an actor or figure strongly illuminated, and concealed from the audience in a sort of enlarged prompter-box. Any one can see the phenomenon completely by looking into a plate glass window on a sunny day, when he sees the passers-by apparently walking *inside* the house.

The principles already stated—rather fully for the explanation of the curious variety of images formed by two *parallel* plane mirrors facing one another at opposite sides of a room. The only additional observation necessary on this subject is that, if the mirrors are silvered on the back, the light at each reflexion has to pass twice through the glass. Thus, if the light be purple or greenish, the various images are more and more colored as they are due to more numerous reflexions.

These principles also easily explain the *Katoptroscope* (*q.v.*) of Sir D. Brewster, where images are formed by two mirrors inclined to one another. It is easy to see that the series of images of a luminous point produced by such an arrangement after one, two, &c., reflexions must all lie on a circle; also that, if the angle between the mirrors be an aliquot part of four right angles, the images will form a finite number of groups, each consisting of an infinite number of images which have exactly the same position.

The explanation of the law of reflexion which is furnished by the corpuscular theory is excessively simple. We have only to suppose that at the instant of its impact on the reflecting surface the velocity of a corpuscle *perpendicular* to the surface is reversed, while that *parallel* to the surface is unchanged. It bounces off in fact like a billiard ball from the cushion. The undulatory theory gives an explanation, which is, in reality, quite as simple, but requires a little more detail for those who are not familiar with the common facts of wave motion. We therefore reserve it for a time.

**Reflexion at a Spherical Surface.**—Let APB (fig. 7) be a section of a concave spherical mirror by a plane passing through its centre of curvature O, and through the luminous point U. Then, if any ray from U, as UP, meet the surface, it will be reflected in a direction PV, such that UP, PO, and PV are in one plane, and so that PO bisects

the angle UPV. (This follows because OP, a radius of the sphere, is normal to the surface at P.) Hence it is

Fig. 7.

rigorously true that, if V be the intersection of PV with UOA,

$$\frac{VO}{VP} = \frac{OU}{UP}.$$

The full consequences of this *exact* statement will be developed under OPTICS (GEOMETRICAL). For our present purpose, an approximation will amply suffice. Let us suppose P to be so near to A that no sensible error is introduced by writing A for P in the above formula. This amounts to supposing the mirror's breadth to be very small in comparison with its radius of curvature. The formula now becomes

$$\frac{VO}{AV} = \frac{OU}{AU}.$$

or, what is the same,

$$\frac{AO - AV}{AV} = \frac{AU - AO}{AU};$$

and V is, to the degree of approximation above stated, independent of the position of the point P. If we call  $r$  the radius AO of the mirror,  $u = AU$  the distance of the source, and  $v = AV$ , the distance of the point V from the mirror, this becomes

$$\frac{r - v}{v} = \frac{u - r}{u}, \text{ or } \frac{1}{u} + \frac{1}{v} = \frac{2}{r}. \quad (a).$$

The formula, or the cut, shows at once that this relation between U and V is *reciprocal*; i.e., all rays from V, falling on the mirror, will be made to converge at U. These points are therefore called *conjugate foci*.

The simplicity of (a) is remarkable; so, also, is that of its interpretation. For the rays passing from a source to a given object, like the mirror, are less and less divergent as the source is farther off. Hence (a) signifies that the (algebraic) sum of the divergences of the incident and reflected rays is equal to that divergence which the mirror can convert into parallelism.

In fact the rigorous geometrical relation may be written in the obvious form  $\angle AVP + \angle AUP = 2\angle AOP$ ,—which, when all three angles are small, is simply (a). A similar statement may easily be made in the case of refraction.

Before we proceed to develop the consequences of this simple formula, we may point out that it is applicable to all cases, —to convergent rays falling on a concave mirror, to divergent rays falling on a convex mirror, &c., &c. The reader may easily verify this by trial for himself. But it follows at once from the necessary interpretation of the negative sign in geometry. Thus, if the mirror were convex, O would be to the *left* of A, as the figure is drawn; and AO, if formerly positive, would now be negative. Thus, for a **convex** mirror, the formula is

$$\frac{1}{u} + \frac{1}{v} = \frac{2}{r}.$$

If the incident rays be *convergent*, U is to the left of A, and therefore AU, or  $u$ , is negative; and so on.

We must now study the *relative* positions of U and V, in order to find the size and position of the image for different positions of the object.

Returning to the formula (a) above, we see that the following pairs of values of  $u$  and  $v$  satisfy it:—

$u$	$v$
Infinite.	$\frac{1}{2}r$ .
Greater than $r$ .	Greater than $\frac{1}{2}r$ , less than $r$ .
$r$	$r$ .
Less than $r$ , greater than $\frac{1}{2}r$ .	Greater than $r$ .
$\frac{1}{2}r$ .	Infinite.
Greater than 0, less than $\frac{1}{2}r$ .	Negative.
0.	0.

Thus, when the source is at a practically infinite distance (as the sun or a star) the image is formed at a distance from the mirror equal to *half* its radius of curvature. It is then said to be in the *principal focus*. As the source comes nearer, the image comes out to meet it, and they coincide at the centre of curvature of the mirror. In fact, a ray leaving the centre of the mirror must meet the surface at right angles, and thus go back by the way it came. When the source comes still nearer, the image goes further off, until, when the source is at the principal focus, the image is at an infinite distance; that is, the rays go off parallel to one another. This is the mode in which a concave reflector is employed for lighthouse purposes. When the source comes still nearer, the image is behind the mirror, i.e., the incident rays are so divergent that part of their divergence remains after reflexion. This remnant of divergence becomes greater and greater as the source is nearer to the mirror, i.e., the (then *virtual*) image comes closer to the mirror, which finally behaves, for a very near source, almost precisely like a plane mirror.

All of these phenomena can be beautifully seen in a dark room by employing a beam of sunlight, rendered distinctly visible, in the fashion noted by Lucretius, by the motes in the air.

For further explanation pictures are given (figs. 8, 9), showing the course of the pencil of rays when (1) a *real* image is formed, and (2) a *virtual* image is formed by a concave mirror.

Fig. 8.

Fig. 9.

and (2) a *virtual* image is formed by a concave mirror. It will be seen at once that, in the case figured, the *real* image is *inverted* and less than the object, the *virtual* image *erect* and larger. In fact the size of a small object is obviously to that of its image in proportion to their distances from O, the centre of curvature of the mirror. Also the image is *erect* when it lies on the same side

of the centre of curvature with the object; inverted, if on the opposite. In other words, the image is inverted if the rays cross one another's path, erect if they do not.

When the breadth of the mirror is large compared with its radius, the approximation upon which all these results depend can no longer be made. There is then no definite image even of a luminous point. It becomes spread over what is called a *caustic*, a section of which is the bright curve familiar to every one who has looked at a cup of milk in sunshine.

Even when the approximation is close enough for ordinary purposes, it is not so for astronomical purposes, and the effect of its inexactness upon the image is known as *spherical aberration*. For the fine mirrors of reflecting *TELESCOPES* (*q.v.*) the spherical form cannot be employed; the surface of the mirror must be of *parabolic* section.

**Cylindrical Mirrors.**—As a simple example of the application of the law of reflexion at curved surfaces, when the rigorous solution is demanded, let us take the case of a vertical right cylinder, the object being a drawing on a horizontal plane. Such mirrors, with the frightfully distorted drawings necessary to give an image of natural proportions, were very common fifty years ago, but are now rarely seen. They are still, however, valuable as illustrations of our subject.

Let the plane of the object on the axis OB of the cylinder at right angles in O (fig. 10), and let A be the position of the eye, and RQA a ray from a point R of the object, reflected at Q. Draw QP perpendicular to the axis. Then AQ and QR are in the same plane with QP (the normal to the surface) and make equal angles with it. Hence, when this figure is projected by vertical lines on the plane of the object, it takes the form in fig. 11; and AQ, QR now make equal angles with OQ. Also, if AB be drawn (in fig. 10) perpendicular to OP, the ratio of AQ to QR in fig. 11 is equal to that of BP to PO in fig. 10.

FIG. 10.

FIG. 11.

Take QS : QQ :: QR : QA, and draw ST parallel to OA. Then it is obvious that

$$JR - ST = \frac{QS}{QQ} OA;$$

and also that the angles QSR and QST are equal. Hence the following theorems, which enable us at once to draw a figure on the object plane such that its image shall appear of any assigned form.

1. Any line, such as QR, on the object plane, drawn from a point Q in the section of the cylinder so that the angles OQR and OQA are equal, is seen after reflexion as a generating line of the cylinder.

2. If an epicycloid be described by lines of fixed length OS, SR, turning about O with angular velocities 1 and 2, and both coinciding with OA at starting, its image will be a circular section of the cylinder.

Thus, if we imagine a drawing on the cylinder any number of vertical and horizontal sections, forming a network, the object corresponding to them can be traced as a number of intersecting straight lines and epicycloids. Thus we have a well known means of drawing the required object. A similar process may be applied to other modes of using such mirrors.

When the cylinder has a small diameter, it may be usefully employed to intercept and reflect part of a beam of sunlight entering a dark room. It is easy to see, by a geometrical construction, that the reflected rays will, in this case, form a right cone, whose axis is that of the cylinder; and one of its generating lines will be parallel to the incident ray. Thus the angle of the cone becomes smaller as the inclination of the reflecting cylinder to the ray becomes less. If the ray, at the point of interruption, was at the centre of a spherical dome, after reflexion it will form on the dome a circle, small or great, which passes through its original point of incidence.

In the language of QUATREPOINTE, let  $\alpha$  be the incident ray,  $\beta$  the axis of the cylinder,  $\tau$  any normal to the cylinder,  $\rho$  the reflected ray. Then the law of reflexion gives

$$V.\tau\alpha\rho = 0$$

The property of the normal gives

$$S\beta\tau = 0.$$

Eliminating  $\tau$ , we have at once

$$\rho^2 = \left( \frac{S\beta\rho}{S\alpha\beta} \right)^2,$$

the equation of a right cone.

Imitations, more or less perfect, of primary and secondary rainbows can easily be made by this process, — the sun-beam being led through a prism just before it falls on the cylindrical rod. This experiment is a very striking one; but, though capable of giving much information, it is of that dangerous kind which is liable to mislead instead of instructing an audience.

If we look at a great number of thin cylindrical rods, parallel to one another, and illuminated by sunlight, the rays which reach the eye must, by what we have already said, each form a side of some right cone (of definite angle) whose axis is parallel to each of the cylinders. The appearance presented will therefore be that of a luminous circle, passing through the sun. Its angular diameter becomes less as the axes of the cylinders are less inclined to the incident rays.

This phenomenon is beautifully shown by some specimens of crystals, especially of Iceland spar, which are full of minute tubes parallel to one another. In a plate of such a doubly-refracting crystal, however, there are necessarily four images. That which is *throughout* due to the ordinary ray (this term will be explained later) shows perfectly the phenomenon above described. The light of the luminous circle is white. The other three curves are not circles, and in them the colours are separated. One of them, which is elliptical, is usually very much brighter than either of the remaining two.

**REFRACTION.** — If homogeneous light be refracted at a plane surface separating two homogeneous isotropic media, the incident and refracted rays are in one plane with the normal to the surface, and the sines of their inclinations to it are in a constant ratio.

Diagram for cylindrical mirror.

Reflexion from polished rod.

Ordinary refraction.

The law of single refraction was put in a form equivalent to this (all but one word) for the first time by Snell in Leyden, some time before 1626. It was first published in 1637 by Descartes, who undoubtedly obtained it from Snell; but he gave it without any mention of its author.

The one word referred to is *homogeneous* as applied to the incident light. For the fact that white light consists of innumerable different homogeneous constituents, which are separated from one another by refraction, was first established by Newton. We quote his own account of this important discovery from his letter to Oldenburg, dated Feb. 6, 1671:

Newton  
on the  
composition of  
white  
light.

"To perform my late promise to you, I shall without further ceremony acquaint you that in the year 1666 at which time I applied myself to the grinding of optick-glasses of other figures than spherical I procured me a triangular glass-prism, to try the with the celebrated phenomena of colours. And in order thereto, having darkened my chamber and made a small hole in my window-shut, to let in a convenient quantity of the sun's light, I placed my prism at its entrance, that it might be thereby refracted to the opposite wall. It was at first a very pleasing diversion, to view the vivid and intense colours produced thereby; but after a while applying myself to consider them more circumspectly, I became surprised to see them in an oblong form; which, according to the received laws of refraction, I expected should have been circular. They were terminated at the sides with straight lines, but at the ends the decay of light was such, that it was difficult to determine justly what was their figure, yet they seemed semi-circular.

"Comparing the length of this coloured *spectrum* with its breadth, I found it about five times greater; a disproportion so extravagant, that it excited in me a more than ordinary curiosity of examining from whence it might proceed. I could not think, that the various thickness of the glass, or the termination with shadow or darkness, could have any influence on light to produce such an effect; yet I thought it not amiss, to examine these circumstances, and so tried what would happen by transmitting light through parts of the glass of divers thicknesses, or through holes in the window of divers bignesses, or by setting the prism without, so that the light might pass through it, and be refracted, before it was terminated by the hole; but I found none of these circumstances material. The fashion of the colours was in all these cases the same.

"Then I suspected, whether by any unevenness on the glass, or other contingent irregularity, the colours might be thus dilated. And to try this, I took another prism like the former, and so placed it, that the light passing through them both, might be refracted contrary ways, and so by the latter returned into that course from which the former had diverted it: for by this means I thought the regular effects of the first prism would be destroyed by the second prism, but the irregular ones more augmented, by the multiplicity of refractions. The event was, that the light, which by the first prism was diffused into an oblong form, was by the second reduced into an orbicular one, with as much regularity as when I did not at all press the light there. So that whatever was the cause of that length, it was not any contingent irregularity.

"I then proceeded to examine more critically, what might be effected by the difference of the incidence of rays coming from divers parts of the sky, and to that end, measured the several lines as they appeared to the eye. Its distance from the hole on the prism was 22 feet; its utmost length 13 inches; its breadth 2½; the diameter of the hole ¼ of an inch. The angle which the rays, sides of the image, made with those lines, as produced without refraction, was 44 deg. 10 min. The angle of the prism 63 deg. 12 min. Also the distance of the hole from the prism, that is, of the incident and emergent rays, I could make them equal; and the rays fell perpendicularly upon the sides of the image. And the rays fell perpendicularly upon the sides of the image, the diameter of the hole from the length and breadth of the image, there remain 13 inches in the length, and 2½ in the breadth, comprehended by those rays which passed through the hole at the side of the hole; and consequently the angle of the hole as seen from the eye, was about 31 min. answerable to the angle of incidence, but the angle which its length subtended, was more than twice its diameter, namely, 2 deg. 49 min.

"Having made these observations, I first computed from them the refractive power of that glass, and found it measured by the ratio of the sines 29 to 31; and then by that ratio I computed the refraction of two rays coming from opposite parts of the sun's *discus*, so as to differ 31 min. in their obliquity of incidence, and found that the emergent rays should have comprehended an angle of about 31 min. as they did before they were incident.

"But because this computation was founded on the hypothesis of

the proportionality of the sines of incidence and refraction, which though by my own experience I could not imagine to be so erroneous, as to make that angle but 31 min. which in reality was 2 deg. 49 min. yet my curiosity caused me again to take my prism: and having placed it at my window, as before, I observed, that by turning it a little about its axis to and fro, so as to vary its obliquity to the light, more than an angle of 4 or 5 degrees, the colours were not thereby sensibly translated from their place on the wall; and consequently by that variation of incidence, the quantity of refraction was not sensibly varied. By this experiment, therefore, as well as by the former computation, it was evident, that the difference of the incidence of rays, flowing from divers parts of the sun, could not make them after decussation diverge at a sensibly greater angle, than that at which they before converged; which being at most but about 31 or 32 min. there still remained some other cause to be found out, from whence it could be 2 deg. 49 min.

"Then I began to suspect, whether the rays, after their trajectory through the prism, did not move in curve lines, and according to their more or less curvity, tend to divers parts of the wall. And it increased my suspicion, when I remembered that I had often seen a tennis-ball, struck with an oblique racket, describe such a curve line. For, a circular as well as a progressive motion being communicated to it by that stroke, its parts, on that side where the ball conspires, must press and beat the contiguous air more violently than on the other, and there excite a reluctancy and reaction of the air proportionally greater. And for the same reason, if the rays of light should possibly be globular bodies, and by their oblique passage out of one medium into another acquire a circulating motion; they ought to feel the greater resistance from the ambient æther, on that side where the motions conspire, and thence be continually bowed to the other. But notwithstanding this plausible ground of suspicion, when I came to examine it, I could observe no such curvity in them. And the sides (which was enough for my purpose) I observed, that the difference betwixt the length of the image and the breadth of the hole, through which the light was transmitted, was proportionable to their distance.

"The undisturbed removal of these suspicions at length led me to the consideration of the rays, which was this. I took two boards, and placed one of them close behind the prism at the window, so that the light might pass through a small hole, made in it for the purpose, and fall on the other board, which I placed at about 12 feet distance. I having first made a small hole in it also for some of that incident light to pass through. Then I placed another prism behind this second board, so that the light trajected through both boards might pass through that also, and be again refracted before it arrived at the wall. This done, I took the first prism in my hand, and turned it to and fro slowly about its axis, so much as to make these several parts of the image, cast on the second board, successively pass through the hole in it, that I might observe to what part of the second prism they would be refracted.

"By this variation of the place, that the light, tending to that one end of the image towards which the refraction of the first prism was directed in the second prism, after a refraction considerably greater than the light tending to the other end. And so the true cause of the length of that image was detected to be no other, than that *but is not similar or homogeneous, but consists of diffracted rays, some of which are more refrangible than others*; so that without any difference in their incidence on the same medium, some shall be more refracted than others; and therefore that, according to their parts or degrees of refrangibility, they were transmitted through the prism to divers parts of the opposite wall."

The constant ratio mentioned in the above statement of Refraction is called the *refractive index*. Its numerical value depends upon the nature of the two media, and also upon the quality of the homogeneous light. It is usually greater for orange light than for red, for yellow than for orange, and so on, so that the violet rays are often called the "more refrangible" rays.<sup>1</sup>

The following experimental facts are additions to the law.

When refraction takes place from a rarer into a denser medium, the angle of refraction is usually less than that of incidence.

If the refractive index for a particular kind of light from a medium A into another B be  $\mu$ , that from B to A is  $\frac{1}{\mu}$ .

In other words, a refracted ray may be sent back by the path by which it came.

If  $\mu_1$  be the refractive index for a particular ray from A

<sup>1</sup> This statement is, however, liable to some very singular exceptions, which will be mentioned later, when we are dealing with anomalous dispersion.

into B, and  $\mu_2$  that for the same ray from A into C, that from B into C is  $\frac{\mu_2}{\mu_1}$ .

These being premised, let us consider a source of homogeneous light in air shining on a surface of water. Here we may take  $\mu$  as about equal to  $\frac{4}{3}$ .

Let MN (fig. 12) be the perpendicular to the water surface at the point where the incident ray AP meets it. In the plane APM make the angle QPN such that

$$\sin APM = \frac{1}{\mu} \sin QPN,$$

then PQ is the refracted ray. If QP be produced backwards to meet the vertical line BA in q, we may present this statement in the form

$$\frac{PB}{PA} = \frac{PB}{Pq},$$

or

$$PA = \frac{3}{4}Pq.$$

If the rays fall nearly perpendicularly on the surface, we may put (approximately) B for P, and we have,

$$Bq = \frac{4}{3}BA.$$

Hence, an eye placed under water and nearly in the vertical through A, sees a *virtual image* of A at q, one-third farther from the surface of the water.

As P is taken farther and farther from A, the angle of incidence becomes more nearly a right angle, and the sine of the angle of refraction becomes more nearly equal to  $\frac{1}{\mu}$ . A ray cannot go from air into water so as to make, with the perpendicular to the surface, an angle whose sine is greater

Fig. 13

than  $\frac{1}{\mu}$ . The true nature of this curious statement is, however, best seen when we suppose the source to be under water, and the light to be refracted into air. If APQ (fig. 13) be the course of a ray, we have as before

$$AP = \frac{3}{4}Pq.$$

Hence, if P<sub>1</sub> be taken so that

$$AP_1 = \frac{3}{4}P_1q,$$

it is clear that q coincides with B, or the ray AP<sub>1</sub>, refracted at P<sub>1</sub>, runs along the surface of the water. If AP<sub>2</sub> be less than  $\frac{3}{4}P_2B$ , no point q can be found; so that the ray AP<sub>2</sub> cannot get out of the water. It is found to be completely reflected in the water. This reflexion unaccompanied by refraction is called *total reflexion*. The limiting angle of incidence (at P<sub>1</sub>) which separates the totally reflected rays

from those which (at least partially) escape into air is called the *critical angle*. When an equilateral triangular critical prism of glass is placed in a ray of sunlight, and made to rotate, we see (besides the spectra formed by refraction) beams of white light reflected alternately from the *outside* and the *inside* of each face. The totally reflected ray from the inside is seen to be very much brighter than that reflected from the outside.

To an object placed nearly in the vertical of A, A appears at A', as

Thus a clear stream, we appear to be at only  $\frac{3}{4}$  the look more and more oblique. ray QP, the image appears or, if A be at the bottom, more shallow, and all of crowded toward the surface immersed in water appear the water.

Again, to an eye at A, all seen within a right cone of a side. The cone itself mentioned, behaves as a perfect mirror.

All this is on the general. But when A<sub>0</sub> will be nearer the greater is the refractive will appear drawn is red and upper end.

It is easily seen passing through a parallel faces, finally one that at incidence, and therefore will it still white. In the plate be wet parallel sides, a body placed close to the other, appears distance from the eye.

The explanation of the law of refraction, on the corpuscular theory, was given by Newton. It is still of importance, as the earliest instance of the involving molecular forces. Newton shows that, as the molecular forces on a corpuscle every point inside either of them constant in each, but that in presence of separation of the two molecules the

refraction of light, on the corpuscular theory, with direction parallel to light comes out from a glass vessel with to one side, while the the depth of its real

raction, on the corpuscular theory, was given by Newton. It is still of importance, as the earliest instance of the involving molecular forces. Newton shows that, as the molecular forces on a corpuscle every point inside either of them constant in each, but that in presence of separation of the two molecules the velocity is N

*Prism.* When the surfaces are plane, but not parallel, Prism, we have what is called a *prism*.

The general nature of the action of a prism will be easily understood by the help of the previous illustration, if we restrict ourselves to the case of a prism of very small angle and to rays passing nearly perpendicularly to each of its faces. Thus, the rays taking nearly at right angles to its surface from a point A (fig. 14) will, after the first refraction, appear to diverge from a luminous line RV, red at the end next to A, violet at the other. This line is in the perpendicular AB from A to the first surface of the prism. Draw from B and V perpendiculars BS, VT to the second surface of the prism. Join BS, BT, and draw Ar, Ae parallel to them so as to cut RS in r and VT in v. To an eye behind the prism, the bright point A will appear to be drawn out into a coloured line rv, red at the end nearest to A.

If *A* be a narrow bright line of light, parallel to the edge of the prism, it will appear to be drawn out into a rectangle consisting of images of the line ranged parallel to one another, and due to the various homogeneous constituents of white light in order of their refrangibility. If the light do not contain rays of every degree of refrangibility, some of these images will be wanting, and there will be corre-

Fig. 14.

sponding dark lines or bands crossin this spectrum (as it is called). The amount by whi any part of this spectrum is shifted from the true position of the bright slit depends (*ceteris paribus*) upon the amount of the refraction. It also depends on the angle of the prism. And, for a given angle, the length of the spectrum depends upon the difference between the refractive indices for the red and the violet rays. This is called the *dispersion*.

If a second prism, of the same glass, and of the same angle, as the first, be placed in a reversed position behind it (as indicated by the dotted lines in the figure), the effect of the two would be simply that of a plate of glass with parallel faces; the emergent rays would each be parallel to its original direction, and there would be no separation of colours. The reversed prism would therefore undo the work of the direct prism. Then we should have no dispersion, but we should also have no refraction. We have, however, as has already been shown, an increase of divergence, *i.e.*, the image is nearer to the eye than the object. Blair, Brewster, and Amici devised combinations of two pairs of prisms of the same glass, those of each pair having their edges parallel, such that the combination acted as a sort of achromatic telescope of low power.

Newton, from some rough experiments, hastily concluded that the amount of dispersion is, in all substances proportional to that of the refraction. If such were the case it is easy to see that prisms of two differently refracting materials and of correspondingly different angles, combined (as above described) so as to annul the dispersion, would likewise annul the refraction. Thus Newton was led to suppose that refraction without dispersion is impossible.

It was found by Hall in 1733, and afterwards (independently) by Dollond, that this idea is incorrect—that, in fact, we have in certain media large refraction with com-

paratively small dispersion, and *vice versa*, and thus that the dispersion may be got rid of while a part of the refraction remains. James Gregory had previously conjectured that this might be done by using, *as is done in the eye*, more media than one. Thus we have for certain specimens of flint and crown glass, whose optical constants were carefully measured by Fraunhofer, the following values of the refractive index for three definite kinds of homogeneous light:—

Flint glass	1.6297	1.6350	1.6483
Crown glass	1.5268	1.5296	1.5860

The rays *C* and *F* are in the red and greenish blue respectively, and are given off by incandescent hydrogen. *D* is the orange yellow ray of sodium.

When the angle of the prism is very small (the only case we treat here), we may consider *Arv* as approximately a straight line, whose length is (*ceteris paribus*) proportional to the angle of the prism. Also the distances *Ar*, *Av*, are to one another in the proportion of the refractive indices of red and violet rays, *each diminished by unity*. Hence, for a prism of flint glass such as was employed by Fraunhofer, the distances from *A* to its images formed by these three kinds of homogeneous light respectively are very nearly as

630, 635, 648.

When a prism of crown glass is used they are nearly as

527, 530, 536.

The differences between the numbers for *C* and *F* are

For flint glass	18
„ crown glass	9

or as 2 : 1. Hence if we make the small angle of the crown-glass prism twice that of the flint, and observe *A* through the two prisms, with their edges turned in opposite directions, the *C* and *F* images will coincide. Both, however, will be displaced from the real direction of *A* as if a prism had been employed, with its edge turned as that of the crown glass was, and to the same extent as that prism would have displaced them had its refractive index been about 1.21 and the same for the two kinds of light *C* and *F*.

In fact, the displacements by the flint prism are as

630, 648,

and those by the crown prism (to the opposite side) are

1054, 1072.

The differences, in favour of the crown prism, are as

424, 424.

This combination of prisms is called *achromatic*, or *colourless*, but is not perfectly so. For if we inquire into the displacement of the *D* image, we find that it is as

635

for the flint prism; but as

1060

in the opposite direction, for the crown prism. Hence its whole displacement is as

425,

a little greater than that common to *C* and *F*. The reason for this is obvious from Fraunhofer's numbers given above. The interval from *C* to *D* is to that from *C* to *F* in a greater ratio in crown than in flint glass—so that the spectra given by these media are not *similar*. The rays of higher refrangibility are more separated in proportion to those of lower refrangibility in flint than in crown glass. This is the *irrationality of dispersion*—which, so far as we yet know, renders absolute achromatism unattainable. Three lenses in combination give a better attempt at achromatism than can be made with two; and some re-

markable results were obtained by Blair,<sup>1</sup> with two glass lenses enclosing a lenticular portion of a liquid.

By looking through a prism at a very narrow slit, formed by the window shutters of a darkened room, Wollaston (in 1802) found that the light of the sky (*i.e.*, sunlight) gives a spectrum which is *not continuous*. It is crossed by dark bands, as already hinted. These bands are due to the deficiency of intensity of certain definite kinds of homogeneous light. They were, independently, rediscovered, and their positions measured, by Fraunhofer<sup>2</sup> in 1817 with far more perfect optical apparatus. He also found similar, but not the same, deficiencies in the light from various fixed stars. The origin of these bands will be explained in RADIATION, along with the theory of their application in spectrum analysis. In optics they are useful to an extreme degree in enabling us to measure refractive indices with very great precision. Wollaston's own account of his discovery is as follows:—

"If a beam of day-light be admitted into a dark room by a crevice  $\frac{1}{4}$ th of an inch broad, and receive by the eye at the distance of 10 or 12 feet, through a prism of flint-glass, *free from veins*, held near the eye, the beam is seen to be separated into the four following colours only, red, yellowish-green, blue, and violet, in the proportions represented in fig. . . . .

"The line A that bounds the red side of the spectrum is somewhat confused, which seems in part owing to want of power in the eye to converge red light. The line B, between red and green, in a certain position of the prism is perfectly distinct; so also are D and E, the two limits of violet. But C, the limit of green and blue, is not so clearly marked as the rest; and there are also on each side of this limit other distinct dark lines *f* and *g*, either of which in an imperfect experiment might be mistaken for the boundary of these colours.

"The position of the prism in which the colours are most clearly divided is when the incident light makes about equal angles with two of its sides. I then found that the spaces AB, BC, CD, DE occupied by them were nearly as the numbers 16, 23, 36, 25."<sup>3</sup>

The mode of formation of a spectrum which was employed by Newton, and which is still used when the spectrum is to be seen by many spectators at a time, differs from that just explained in this, that the light from a source A is allowed to pass through the prism, and to fall on a white screen at a considerable distance from it. In this case the paths of the various rays as they ultimately escape from the prism are found by joining the points *r*, . . . . *v*, with the prism and producing these lines to meet the screen. Unless one surface of the prism be covered by an opaque plate, with a narrow slit in it parallel to the edge of the prism, the spectrum produced in this way is very *impure*, *i.e.*, the spaces occupied by the various homogeneous rays overlap one another. To make it really pure an achromatic lens is absolutely requisite. This leads us, naturally, to the consideration of the refraction of light at spherical surfaces.

**Refraction at a Spherical Surface.**—Following almost exactly the same course as that taken with reflexion above, let O (fig. 15) be the centre of curvature of the spherical refracting surface AB. Let U be the point-source of homogeneous light, and let PV be the prolongation (backwards) of the path pursued, after refraction, by the ray UP.

Then, *rigorously*, we have

$$\sin UPO = \mu \sin OPV,$$

where  $\mu$  is the index of refraction between the two media employed. This may be written (by omitting a common factor) as

$$\frac{OP}{PV} = \frac{OV}{PA}.$$

If, as before, the breadth of the surface be small compared with its radius of curvature, we may approximate

Fig. 15.

(sufficiently for many important practical purposes) by writing A for P. Thus we have

$$\frac{OP}{AV} = \frac{OV}{PA}.$$

Retaining the same notation as in the case of reflexion, we get

$$\frac{u - r}{v} = \frac{\mu - 1}{\mu} \frac{r}{s},$$

or

$$\frac{\mu}{v} = \frac{1}{u} + \frac{\mu - 1}{s} \quad (1).$$

Notice that, if we put  $\mu = 1$ , this becomes the formula for *reflexion* at a concave mirror.

**Lenses.**—Suppose now that, after passing a *very short* thin distance into the refracting medium, the ray escapes again into air through another spherical surface whose centre of curvature also lies in the line OV. Let *s* be the new radius of curvature,  $\mu$  the value of the quantity corresponding to  $v$  for the escaping ray. Then, remembering that the refractive index is now  $\frac{1}{\mu}$ , we have (by the previous formula)

$$\frac{1}{\mu} = \frac{1}{u} + \frac{1}{s} - \frac{1}{v},$$

or

$$\frac{1}{v} = \frac{1}{u} + \frac{1}{s} - \frac{\mu}{r} \quad (2).$$

Adding (1) and (2) we get rid of *v*, which indicates the behaviour of the rays in the substance of the lens, and have

$$\frac{1}{v} = \frac{1}{u} + \frac{1}{s} - \frac{\mu - 1}{r} \left( \frac{1}{r} + \frac{1}{s} \right).$$

This contains the whole (approximate) theory of the behaviour of a very thin lens.

When the source is at an infinite distance, or  $u = \infty$ , we have

$$\frac{1}{v} = \frac{1}{s} - \frac{\mu - 1}{r} \left( \frac{1}{r} + \frac{1}{s} \right).$$

*f* suppose.

This quantity *f*, defined entirely in terms of the refractive index and of the curvatures of the two faces of the lens, is called the *principal focal distance*. If  $\mu$  be greater than 1, *i.e.*, as in the case of a glass lens in air, *f* is *positive* if

$$\frac{1}{r} - \frac{1}{s}$$

be so; and it obviously retains the same value, and sign, *Reversed*, if the lens be turned round. For, in the formula, *r* and *s* change places, and they also change signs, *i.e.*, we must

<sup>1</sup> *Trans. R.S.E.*, vol. iii. (1791).

<sup>2</sup> *Gilbert's Annalen*, lvi.

<sup>3</sup> "The correspondence of these lines with those of Fraunhofer I have, with some difficulty, ascertained to be as follows:—

A, B, *f*, C, *g*, D, E, . . . Wollaston's lines.

B, D, *f*, *g*, F, G, H, . . . Fraunhofer's lines.

There is no single line in Fraunhofer's drawing of the spectrum, nor is there any in the real spectrum, coincident with the line C of Wollaston's, and indeed he himself describes it as not being 'so clearly marked as the rest.' I have found, however, that this line C corresponds to a number of lines half-way between *b* and *F*, which, owing to the absorption of the atmosphere, are particularly visible in the light of the sky near the horizon."—Brewster, *Report on Optics*, Brit. Association, 1832.

put  $-s$  for  $r$  and  $-r$  for  $s$ . This leaves the result unchanged.

All lenses, therefore, whose sections are of any of the forms in fig. 16, whichever way they are turned, render

FIG. 16.

parallel rays which pass through them *diverge*. Their characteristic is that they are thinnest at the middle. But

is negative for lenses whose sections are of any of the forms shown in fig. 17. Such lenses, whichever way they are turned, render parallel rays *convergent*. Their characteristic

FIG. 17.

is that they are thickest at the middle. But these characters are interchanged when  $\mu$  is less than 1; as, for instance, when the lens is an air-space surrounded by water. The similarity on reversal is *not* in general true in a second approximation.

The formula for a thin lens now takes the form,

$$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$$

and differs from that for a curved reflecting surface only in the sign of the second term. With the proper allowance for this, then, all that we have said of reflexion at spherical mirrors holds true of refraction through thin lenses with spherical surfaces.

We may now put the whole matter in the excessively simple form which follows:—

*A thin lens increases or diminishes by a definite quantity the convergence or divergence of all rays which pass through it.*

This quantity is the divergence or convergence of rays falling on the lens from or passing from it to its principal focus. Or it is the convergence or divergence which the lens produces in parallel rays. Thus, if the distance of an object from a convex lens is twice the focal length of the lens, the image is formed at the same distance from the lens, and is equal in size to the object.

Images produced by lenses. Figs. 18 and 19 show the production of a real image and of a virtual image by lenses which produce *convergence* of parallel rays—along with the rays by which these are seen by an eye placed behind the lens. In either case it is obvious that the sizes of object and image are, respectively, as their distances from the centre of the lens.

Fig. 18 shows how a lens produces a real inverted image of a body placed farther from it than its principal focus. This is the case in the camera obscura, in the solar

Fig. 18.

microscope, and in the object glass of a telescope. Fig. 19 shows how a virtual image is formed of a body placed nearer to a lens than its principal focus. This is the case of a single lens used as a microscope. In the former case the divergence of the incident rays is so small that the lens renders them convergent. In the latter the divergence is so great that the lens can only diminish, not destroy it.

in using a hand-magnifier in this way, we so adjust it, by practice, that the enlarged image appears to be formed at the distance from the eye at which vision is most distinct. It is obvious that the amount of magnification must, then, be greater as the focal length of the lens is less.

We can now understand the working of the ordinary astronomical telescope (fig. 20). The object glass furnishes an inverted but real image of a distant body, *within our reach*. We can, therefore, place the eye-glass (like the single microscope above spoken of) so as to form a virtual magnified image of this real image treated as an object. It is still, of course, inverted. It is easy to see that the

Fig. 20.

angle subtended at the eye by the virtual image seen through the eye-piece is to that subtended by the object at the unaided eye approximately as the focal length of the object lens is to that of the eye lens. These angles are, in fact, those subtended at the centres of the two lenses by the real image. This ratio is, therefore, called the *magnifying power* of the telescope.

The compound microscope, in its simplest form, is precisely the same arrangement as the astronomical telescope. The only difference is that the object, being at hand, can be placed near to the object-glass (still, however, beyond its principal focus), so that the real image formed is already considerably larger than the object, and is then still further magnified by the eye-glass.

The magnifying power of a single lens, when used as a hand microscope, is to be measured by the ratio of the angle under which the virtual image of an object is seen (at the distance of most distinct vision) to that at which the object itself would be seen (at that same distance); i.e., it is the ratio of 10 inches to the focal length of the lens.

**Lenses in contact.** Combinations of Lenses in Contact.—From the formula

$$\frac{1}{f} = (\mu - 1) \left( \frac{1}{r} + \frac{1}{s} \right)$$

we see that the focal length of a simple lens is less as  $\mu$  is greater. Thus all that we have just said is true for homogeneous light alone. But if we combine two thin lenses, placing them close together, we may arrive at an approximately achromatic arrangement. For we have, for the first lens

$$\frac{1}{f} = (\mu - 1) \left( \frac{1}{r} + \frac{1}{s} \right)$$

For a second, close to it, we have

$$\frac{1}{x} = (\mu' - 1) \left( \frac{1}{r'} + \frac{1}{s'} \right)$$

For the two, considered as one, we have

$$\frac{1}{u} = (\mu - 1) \left( \frac{1}{r} + \frac{1}{s} \right) + (\mu' - 1) \left( \frac{1}{r'} + \frac{1}{s'} \right)$$

Now

$$\frac{1}{f} + \frac{1}{f'} = (\mu - 1) \left( \frac{1}{r} + \frac{1}{s} \right) + (\mu' - 1) \left( \frac{1}{r'} + \frac{1}{s'} \right)$$

and there is an infinite number of ways in which  $r'$  and  $s'$  can be chosen, when  $r$  and  $s$  are given, such that the values of the right hand side shall be equal for two values of  $\mu$  and the corresponding values of  $\mu'$ . Any one of these gives an achromatic combination, of the necessarily imperfect kind described above in considering prisms. But, as we have now the curvatures of four surfaces to deal with, we can adjust these so as not only to make the best attainable approximation to achromatism, but also to reduce the unavoidable spherical aberration to a minimum.

These questions, however, are beyond the scope of this article. We can remark only that the adjustment for two rays, for which the refractive indices are  $\mu$  and  $\mu + \delta\mu$  in the first medium, and  $\mu'$  and  $\mu' + \delta\mu'$  in the second, requires the one relation

$$\frac{\delta\mu}{\mu - 1} \cdot \frac{1}{f} + \frac{\delta\mu'}{\mu' - 1} \cdot \frac{1}{f'} = 0,$$

which involves only the ratio of the focal lengths of the two lenses—leaving their forms absolutely undetermined. But, if both  $\mu$  and  $\mu'$  be greater than unity, the signs of  $f$  and  $f'$  must be different;—i.e., in an achromatic combination of two lenses one must be convex and the other concave.

The reader must, however, be reminded that we are dealing with a first approximation only, and that spherical aberration does not come in till we reach a second. The details for a proper achromatic combination will be given in OPTICS (GEOMETRICAL).

Before leaving this subject, we must find the behaviour of two thin lenses which are placed at a finite distance from one another. For the first lens we have, as before,

$$\frac{1}{x} = (\mu - 1) \left( \frac{1}{r} + \frac{1}{s} \right)$$

If the second lens be placed at a distance  $a$  behind the first, the rays which fall on it appear to come from a distance  $w + a$ . Hence, for the light emerging from the second lens, we have

$$\frac{1}{x} = (\mu - 1) \left( \frac{1}{r} + \frac{1}{w + a} \right) + (\mu' - 1) \left( \frac{1}{r'} + \frac{1}{s'} \right)$$

When  $a$  is infinite, we have from the last two equations

$$\frac{1}{x} = (\mu - 1) \left( \frac{1}{r} + \frac{1}{f} \right) + (\mu' - 1) \left( \frac{1}{r'} + \frac{1}{f'} \right)$$

It is obvious that a combination of this nature offers the

same kind of facilities for the partial cure of dispersion and of spherical aberration as when the lenses are in contact, with one additional disposable constant. Thus we have compound achromatic eyepieces, which can be corrected for spherical aberration also.

**Formation of a Pure Spectrum.** We may now go back Pure to the formation of an image by a prism, and inquire spectrum. how, by the use of an achromatic lens, we can project a pure spectrum on a screen. We have seen that a thin prism, for rays falling nearly perpendicular to it, forms a virtual and approximately rectilinear image of a luminous point, in which the colours are ranged in order of refrangibility. Suppose the light which passes through the prism to fall on an achromatic lens placed at a distance greater than its focal length from the virtual image above mentioned. The rays, passing through the lens, will proceed to form, on the other side, a real linear coloured image of the luminous point, in which (as in the virtual image) the colours do not overlap. Instead of a luminous point, rays diverging from a very narrow slit parallel to the edge of the prism are employed. It is usual to place the lens at  $\frac{1}{2}$  its focal distance from the virtual image, and thus a real image is formed at an equal distance on the other side of it, and of the same size. It may now, if required, be viewed by means of an achromatic eyepiece. Or, in other words, it may be examined by means of a telescope. In fact a telescope, whose object glass is covered by the prism, has been usefully employed during a total eclipse, for examining the light of the solar corona. A similar arrangement, made to have an exceptionally large field of view, is employed to find the nature of the spectrum of distant celestial objects.

**Refraction at a Cylindrical Surface.** A very simple, cylindrical but interesting, case of refraction at a cylindrical surface is furnished by a thermometrical bulb, in which a liquid is furnished by a thermometrical bulb. It is easily seen that the diameter of the bulb appears, when viewed at a distance large as compared with the diameter of the bulb, to be greater than it really is, in the proportion of the refractive index of the glass to unity. The effect of this magnification is magnified in about a ratio 5:1. Hence the mercury appears completely full. If the external surface of such a tube, if the bore be only  $\frac{1}{16}$  of the external diameter.

But a far more interesting case than that of parallel rays falling on a solid cylinder of transparent material. Its interest consists in the fact that by its aid we can explain the phenomena of the rainbow. We accordingly devote special attention to it. The problem, however, being any of its applicability to the rainbow, is much simplified by supposing the rays to be incident in a direction perpendicular to the axis of the cylinder, for in this case the whole course of each ray is in a plane perpendicular to the axis. We need not fret here of rays which pass close to the axis of the cylinder. For such the cylinder acts as a lens, and its focal length (to the usual first approximation) can easily be obtained by methods such as those given above.

What we are mainly concerned with is the behaviour of the rays which escape into the air, after one or two reflexions at the inner surface of the cylinder.

Suppose first that we consider a ray once reflected in the interior of the cylinder. Let SP (fig. 21) be one of the set of incident parallel rays, and let its path be SPQS. This involves refraction at P, reflexion at Q, and again refraction

Fig. 21

Achromatic eyepieces.

tion at  $P'$ . But it is obvious from the symmetry of the circular section, and from the laws of refraction and reflexion, that this path is symmetrical about the line  $OQ$  which joins the axis of the cylinder to the point at which the ray is reflected. Hence  $SP, S'P'$  meet  $OQ$  in the common point  $s$ ; and the amount by which the direction of the ray has been turned round by the refractions and the reflexion is twice the supplement of half the angle at  $s$ . But the angle  $POQ$  is double  $OPQ$  the angle of refraction, while  $OPi$  is equal to the angle of incidence. Hence the half angle at  $s$  is the excess of twice the angle of refraction over the angle of incidence.

Turn now to fig. 22, in which we have two concentric circles whose radii are to one another as the refractive index of the cylinder is to unity. If  $A$  be any point on a diameter, and tangents  $Ap$  and  $Aq$  be drawn from it, we see at once that the sines of the angles at  $A$  are to one another as the radii of the circles. Hence, if  $OAp$  be the angle of incidence,  $OAg$  is the corresponding angle of refraction; and it is easy

Fig. 22.

to see that the half angle at  $s$  (in fig. 21) will in fig. 22 be represented by the excess of  $OAg$  over  $qAp$ . Now when  $OA$  is large, both of these angles are small, and thus their difference is likewise small. As  $OA$  becomes less the difference of the angles becomes greater, but only up to a certain point, for when  $A$  is near the outer circle the angle  $OAp$  begins to increase much faster than does  $OAg$ . Hence there is a single definite position of  $A$  for which the difference is a maximum. In the first figure these changes in the angles of incidence and refraction, for the members of a group of parallel rays, correspond to the varying position of  $P$  in the circular section of the cylinder. Hence there is one position of  $P$  for which the angle at  $s$  is a maximum. Now one of the conditions of a maximum or minimum of any quantity is that, near it, the value of the quantity changes very slowly. Thus a number of issuing rays are crowded together near the direction corresponding to this maximum, the others being more widely scattered,—while for all of them the angle at  $s$  is smaller. Newton gives us as an illustration of this, the very slow change of length of the day when the sun is near one of the tropics.

To find this Maximum Angle. If  $\theta$  be the angle of incidence,  $\phi$  that of refraction, and  $\mu$  the refractive index, we have to find the maximum value of

$$\frac{1}{2}s = 2\phi - \theta \quad (1)$$

with the condition

$$\sin \theta = \mu \sin \phi \quad (2)$$

This gives at once

$$2\phi \cos \phi = \theta,$$

and

$$\mu \cos \phi \, d\phi = \cos \theta \, d\theta.$$

Hence

$$\mu \cos \phi = 2 \cos \theta \quad (3)$$

From (2) and (3)

$$4 \cos^2 \theta = \mu^2 - 1;$$

which determines the angle of incidence. The values of the other quantities are then calculated from this, and we finally have, for the value of the half angle at  $s$ , the expression

$$\frac{1}{2}s = \left(1 - \frac{\mu^2}{4}\right) \quad (4)$$

This is obviously smaller as  $\mu$  is greater, at least up to the limit  $\mu = 2$ .

With the value 1.33 for  $\mu$  (which is nearly that for yellow rays refracted into water) we have

$$\frac{1}{2}s = 9.55462,$$

respectively, corresponds very nearly to

$$3s = 21^\circ 1'.$$

Now suppose the diameter of the cylinder to be small compared with the distance of the eye from it. In this case the point  $s$  may be considered as being in the axis of the cylinder.

Let  $SsE_1$  (fig. 23) be made equal to the maximum value of  $s$ ; then an eye placed anywhere in the line  $sE_1$  will receive the rays which are congregated towards the maximum. An eye within the angle  $SsE_1$  (as at  $E_2$ ) will receive some of the straggling rays, while an eye outside that angle (as at  $E_3$ ) will see nothing. Let there now be imagined a great number of parallel cylinders; let  $E_1a$  be drawn parallel to the incident rays, and make the angle  $\sigma E_1s$  equal to  $\sigma E_1s$ . Then the eye at  $E_1$  will see the concentrated rays (already spoken of) in the directions  $E_1s$  and  $E_1s'$ . From points within  $sE_1s'$  some straggling rays will reach it, from points outside that angle none.

Fig. 23.

Now suppose cylinders to be placed in great numbers in all directions perpendicular to the incident rays. The rainbow eye at  $E_1$  will see a bright circle of light whose centre is in  $E_1\sigma$ . Inside that circle there will be feeble illumination; outside it, darkness. This is obviously the case of the rainbow, where we have spherical drops of water instead of the cylinders above spoken of. For each spherical drop is effective only in virtue of a section through its centre, containing the incident ray and the eye; and such sections are the same as those of the cylinders.

Thus far we have been dealing with parallel rays of homogeneous light; and the appearance (to the degree of approximation we have adopted) is that of a bright circle whose centre is diametrically opposite to the source of light, whose radius is (for raindrops) about  $42^\circ 2'$ , and whose area is slightly illuminated.

Introduce the idea of the different kinds of homogeneous light which make up sunlight, and we find a circular (almost pure) spectrum—the less refrangible rays being on the outside. Next we introduce the consideration of the finite disk of the sun, and we have an infinite series of such disks or arrangements superposed on one another, the centre of each individual of the series being at the point diametrically opposite to the point of the sun's disk which produced it. This leaves the general aspect of the phenomenon unchanged, but altogether destroys the purity of the spectrum.

If we next consider light which has been twice reflected within the cylinder, we have a figure like the diagram fig. 24; where the lettering is as nearly as possible the

Fig. 24.

same as that in fig. 23. Everything is still symmetrical about the line  $O\sigma$ , which obviously cuts at right angles the ray  $QQ'$ .

Reasoning precisely similar to that above given shows that the complement of half the angle at  $s$  is now equal to the excess of thrice the angle of refraction ( $OPQ$ ) over that of incidence (the supplement of  $OPi$ ), and that this also has a maximum value, i.e., that  $s$  itself has a minimum value.

$$\frac{\pi}{2} - 3\phi - \theta,$$
$$\sin \theta = \mu \sin \phi.$$
$$8 \cos^2 \theta = \mu^2 - 1,$$
$$\sin \frac{1}{2} \theta = \frac{\mu^4 + 18\mu^2 - 27}{8\mu^3}$$
$$\frac{1}{8} \left( \frac{9}{\mu^2} - 1 \right)^2,$$

For  $\mu = \frac{1}{2}$  the value of  $\sin \frac{1}{2}s$  is

so that

**any time  
now**

The explanation was then thought to be complete. For a long time this was held to be one of Newton's most brilliant discoveries. It is well to notice that he himself speaks of it, in its true relation to the work of his predecessors. He merely says:—"But whilst they understood not the true origin of colours, it is necessary to pursue it here a *little further*." And he said well; for a full investigation conducted on the principles of the undulatory theory introduces, as was first pointed out by Young, certain important modifications in the above statements. Of these we need mention only one, viz., that in each bow there is more than one maximum of brightness for each homogeneous ray.

\* Newton, in his *Optics*, says the work of De Dominis was written twenty years before it was published.

mathematical optics can only *then* attain a coordinate rank with mathematical mechanics . . . , when it shall possess an appropriate method, and become the unfolding of a central idea. . . . It appears that if a general method in deductive optics can be attained at all, it must flow from some law or principle, itself of the highest generality, and among the highest results of induction. . . . [This] must be the principle, or law, called usually the Law of Least Action; suggested by questionable views, but established on the widest induction, and embracing every known combination of media, and every straight, or bent, or curved line, ordinary or extraordinary, along which light (whatever light may be) extends its influence successively in space and time: namely, that this linear path of light, from one point to another, is always found to be such that, if it be compared with the other infinitely various lines by which in thought and in geometry the same two points might be connected, a certain integral or sum, called often *Action*, and depending by fixed rules on the length, and shape, and position of the path, and on the media which are traversed by it, is less than all the similar integrals for the other neighbouring lines, or, at least, possesses, with respect to them, a certain *stationary* property. From this Law, then, which may, perhaps, be named the Law of STATIONARY ACTION, it seems that we may most fitly and with best hope set out, in the synthetic or deductive process and in the search of a mathematical method.

Accordingly, from this known law of least or stationary action I deduced (long since) another connected and co-extensive principle, which may be called by analogy the LAW OF VARYING ACTION, and which seems to offer naturally a method such as we are seeking; the one law being as it were the last step in the ascending scale of induction, respecting linear paths of light, while the other law may usefully be made the first in the descending and deductive way.

The former of these two laws was discovered in the following manner. The elementary principle of straight rays showed that light, under the most simple and usual circumstances, employs the direct, and therefore the shortest, course to pass from one point to another. Again, it was a very early discovery attributed by Laplace to Ptolemy, that, in the case of a plane mirror, the bent line formed by the incident and reflected rays is shorter than any other bent line having the same extremities, and having its point of bending on the mirror. These facts were thought by some to be instances and results of the simplicity and economy of nature; and Fermat, whose name has on measure and measure been claimed by the Continental mathematicians as the genius of the differential calculus, could anxiously to trace some small economy in the more complex case of refraction. He believed that by a metaphysical or conventional necessity arising from the simplicity of the universe light always takes the course which it can traverse in the shortest time. To reconcile the metaphysical opinion with the law of refraction, discovered experimentally by Snellius, Fermat was led to suppose that the two lengths, or *optical*, which Snellius had measured on the incident ray prolonged, and on the refracted ray, and had observed to have one common proportion on a refracting plane, are inversely proportional to the two successive velocities of the light before and after refraction, and therefore that the velocity of light is decreased when it enters a denser media in which it is observed to spread at the perpendicular; for Fermat believed that the time of propagation of light along a line bent by refraction was equal to the sum of the two products, of the incident portion multiplied by the index of the first medium, and of the refracted portion multiplied by the index of the second medium; because he found, by his mathematical method, that this sum was less, in the case of optical refraction, than if light went by any other than its actual path from one given point to another, and because he perceived that the imposition of a velocity inversely as the index reconciled his mathematical discovery of the minimum of the foregoing sum with his knowledge of principle of least time. Descartes attacked Fermat's opinion respecting light, but Leibnitz, Zedler, and others, and Huygen's theory is led, by reasonings of a very different kind, to adopt Fermat's conclusions of a velocity inversely as the index, and of a *constant time* of propagation of light, as a result from a given point to another through an ordinary refracting plane. Newton, however, by his theory of emission and attraction, was led to conclude that the velocity of light was *directly* as the index, and that it was *increased* instead of *decreased* when it entered a denser medium; a result incompatible with the theorem of the shortest time in refraction. This theorem of least time was accordingly abandoned by many, and among the first by Maupertius, who, however, proposed in its stead, as a new conventional principle, that *celestial law of least action* which has since acquired so high a rank in mathematical physics, by the improvements of Euler and Lagrange.

Maupertius gave the name of *action* to the product of space and velocity, or rather to the sum of all such products for the various elements of any motion, observing that the more space has been traversed and the less time it has been traversed in, the more action may be considered to have been expended, and by combining this idea of action with Newton's estimate of the velocity of light as

increased by a denser medium, and as proportional to the refracting index, and with Fermat's mathematical theorem of the minimum sum of the products of paths and indices in ordinary refraction at a plane, he concluded that the course chosen by light corresponded always to the *least possible action*, though not always to the least possible time. He proposed this view as reconciling physical and metaphysical principles which the results of Newton had seemed to put in opposition to each other; and he soon proceeded to extend his law of least action to the phenomena of the shock of bodies, Euler, attached to Maupertius, and pleased with these novel results, employed his own great mathematical powers to prove that the law of least action extends to all the curves described by points under the influence of central forces; or, to speak more precisely, that if any such curve be compared with any other curve between the same extremities, which differs from it indefinitely little in shape and in position, and may be imagined to be described by a neighbouring point with the same law of velocity, and if we give the name of action to the integral of the product of the velocity and element of a curve, the difference of the two neighbouring values of this action will be indefinitely less than the greatest linear distance (itself indefinitely small) between the two near curves; a theorem which I think may be advantageously expressed by saying that the action is *stationary*. Lagrange extended this theorem of Euler to the motion of a system of points or bodies which act in any manner on each other; the action being in this case the sum of the masses by the foregoing integrals.

Laplace has also extended the use of the principle in optics, by applying it to the refraction of crystals, and has pointed out an analogous principle in mechanics, for all imaginable connexions between force and velocity.

We give, first, a very brief indication of the nature of Hamilton's Varying method, as applicable directly to the corpuscular theory. Here the *action* of a corpuscle is the quantity which possesses the stationary Corpuscular property. Let  $v$  be the velocity at any point  $x, y, z$  of the medium,  $ds$  an element of the path,  $\alpha, \beta, \gamma$  the direction cosines of  $ds$ , which theory. as supposed to enter linearly and homogeneously into the expression for  $\lambda$ . Then the action  $V$  is given by

$$V = \int v ds.$$

Hence, for a path nowhere finitely distant from the first,

$$\delta V = \int (\delta v ds + v \delta ds).$$

But

$$\begin{aligned} \delta v &= \frac{dv}{dx} \delta x + \frac{dv}{dy} \delta y + \frac{dv}{dz} \delta z \\ &= \frac{dv}{d\alpha} \delta \alpha + \frac{dv}{d\beta} \delta \beta + \frac{dv}{d\gamma} \delta \gamma, \end{aligned}$$

the first three terms depending on the *translation* of the element  $ds$ , the others, on its *change of direction*, and all the differential coefficients being partial. The homogeneity of  $v$  gives

$$\alpha \frac{dv}{d\alpha} + \beta \frac{dv}{d\beta} + \gamma \frac{dv}{d\gamma} = v.$$

Also

$$\delta ds = \delta x \alpha + \delta y \beta + \delta z \gamma = \delta \alpha ds + \delta \beta ds + \delta \gamma ds,$$

with  $\alpha^2 + \beta^2 + \gamma^2 = 1$ , and  $\alpha, \beta, \gamma$  functions of  $y$  and  $z$ .

By the help of the above, and a partial integration of the factors  $\delta \alpha, \delta \beta, \delta \gamma$ , we have

$$\begin{aligned} \delta V &= \frac{dv}{d\alpha} \delta \alpha + \frac{dv}{d\beta} \delta \beta + \frac{dv}{d\gamma} \delta \gamma \\ &+ \int \left[ \delta x \left( \frac{dv}{d\alpha} \alpha + \frac{dv}{d\beta} \beta + \frac{dv}{d\gamma} \gamma \right) + \dots \right], \end{aligned}$$

where the integrated part is to be taken between proper limits.

If the initial and final points of the path be fixed,  $\delta x, \delta y, \delta z$ , vanish in the integrated part, and the stationary condition shows that we must have

$$\frac{dv}{d\alpha} \alpha + \frac{dv}{d\beta} \beta + \frac{dv}{d\gamma} \gamma = 0,$$

with other two similar conditions, only two of the three being independent because of the necessary relation

$$\alpha^2 + \beta^2 + \gamma^2 = 1.$$

These may be regarded as the differential equations of the ray, or path of the corpuscle.

But the essence of Hamilton's method of *varying action* depends upon a change of the terminal point of the ray, and leads at once to the three equations

$$\frac{\delta V}{\delta x} = \frac{dv}{d\alpha}, \quad \frac{\delta V}{\delta y} = \frac{dv}{d\beta}, \quad \frac{\delta V}{\delta z} = \frac{dv}{d\gamma},$$

which follow directly from the general value of  $\delta V$  above, by taking account of the vanishing of the unintegrated part in consequence of the stationary condition. We may now write  $d$  for  $\delta$  everywhere in these expressions.

homogeneity in a refracting medium is capable of producing phenomena of the most extraordinary character.

**Mirage.** It is difficult to ascertain exactly what is the condition of the atmosphere when multiple images, mirage, &c., are seen; and it is obvious from the remarks and illustrations already given that many very different arrangements will produce sensibly the same result to a spectator in a given position. Comparison of the appearances seen simultaneously by a great number of scattered observers is the only way in which we can expect to obtain definite information on such a point. But the following investigation suggests the general nature of the explanation.

If we suppose the refractive index of the air to depend only upon the vertical height above the earth's surface, rays will all travel in vertical planes, and Hamilton's equation (neglecting the curvature of the earth's surface) takes the very simple form

$$\frac{d\tau}{dx} = \frac{f(dx)^2 - f(y)}{(dy)^2 - f(y)},$$

$x$  being measured horizontally, and the refractive index being proportional to  $\sqrt{f(y)}$ .

This equation gives, as before,

$$\tau = ax + \int dy \sqrt{f(y) - a^2},$$

and the equation of the path of a ray is

$$\frac{d\tau}{da} = A = x - a \int \frac{dy}{\sqrt{f(y) - a^2}}.$$

Here, on the corpuscular theory,  $a$  is the horizontal velocity of the light, and  $\sqrt{f(y) - a^2}$  the vertical velocity. If the form of  $f$  and the value of  $a$  be such that we can have  $f(y) - a^2 = 0$ , it is clear that at  $y = \eta$  the ray is for a moment horizontal. The form of equation of the ray shows that it has a *vertex* at this point, and that it is symmetrical about a vertical axis passing through the vertex. If  $\xi, \eta$  be the coordinates of the vertex for a ray passing through the point  $0, b$ , we have the relation

$$\xi = \sqrt{f} \int_0^b \frac{dy}{\sqrt{f(y) - f(\eta)}}.$$

This is the equation of the locus of the vertices of all rays which, starting from a given point, return again to the same level. To find, then, the various rays by which a distant object near the horizon can be seen, all that we have to do is to draw the curve of vertices which passes through the eye of the spectator, and to find the points in which it is intersected by a vertical line situated midway between the object and the eye. Each of the points is the vertex of a ray by which the object is seen. When the curve of vertices lies forward to and behind the eye, one of these points, two contiguous images are seen; when it is tangent to the eye, one image is erect, and an inverted image.

Now, when the curve of vertices is traced, from the above formula, for any horizontal stratum of air from a greater value below the stratum, the value above it, it is found that the stratum can in general be cut by a vertical line in one point. But if the refractive index have a nearly stationary value at the upper boundary of the stratum the curve of vertices is cut twice, or not at all by a vertical line. When there is no intersection we have only the direct image; but when there are two intersections a distant ship will be seen as usual uniform air, while there will be seen above it an image, and then a direct image, both due to the stratum.

This is a form of mirage very commonly seen at sea. The stationary value of the index at the upper boundary of the stratum is not given by the stratum, however, turned upside down, explain the phenomenon.

an image at some distance above (suggesting reflexion from a pool or lake) formed by the hot layer of air near the sand.

**Scatter- and absorption.** **ABSORPTION.** **FLUORESCENCE.** We must now take up the third and fourth of the categories under which light incident on the bounding surface of two media may fall—*scattering and absorption*. We take them together, because in the great majority of bodies, as we have already seen, scattering takes place not merely at the surface but within some distance below the surface, which in general is small, but in some cases considerable. And when the scattering takes place, even in part only, below the surface, the scattered light is usually modified by absorption.

See especially Vince, in the Bakerian Lecture, *Phil. Trans.*, 1799.

An excellent instance of this scattering from below the surface is afforded by a mass of thin films or small particles of transparent bodies, such as glass, water, or ice. Thus bounded glass, froth or foam, snow, clouds, &c., appear brilliantly white in sunlight, and are, in consequence, opaque when in layers of sufficient thickness. Here the light is obviously scattered by reflexion. What passes through one film, crystal, or particle is, in part, reflected from the next, and so on.

Even when the froth consists of bubbles of a highly coloured liquid, such as port for instance, it usually shows but slight traces of colour, for the great majority of the scattered rays have passed through very small thicknesses only of the liquid. In the same way, very finely bounded blue or red glass (unless it be exceedingly deeply coloured when in mass) appears nearly white. But when a mass of water is full of air bubbles, as, for instance, the case in the neighbourhood of a breaker, the light of the reflected from the surfaces of these bubbles suffers a double absorption by the water before it reaches the eye. This is one of the causes of the exquisite colours of the sea. Near shore, or in shoal water, another cause sometimes comes into play, viz., fine solid particles suspended in the water. When such particles, whether in air or in water, are exceedingly small, they may produce colours due to their minuteness alone, and not to their own colour nor to the absorptive properties of the medium. This, however, is a question of physical optics.

In general, even the most highly coloured opaque or translucent solids, such as painted wood or stained paper, are visible by scattered light whatever portion of the spectrum falls on them. This is very well seen with highly coloured paper-hangings, when illuminated by homogeneous light, such as that of a sodium flame (a Bunsen flame, into which is thrust a platinum wire dipped in strong brine). The red, orange, and yellow parts usually appear very bright under such treatment, the blue parts appearing but slightly illuminated. The colour of all is, of course, that of the incident light. It appears, therefore, that some of the light is scattered from the surface. It is by this, for instance, that the blue parts are feebly visible. But that which is scattered from the portions coloured red, orange, &c., must come mainly from under the surface.

An excellent proof of this is furnished by mixing, in proper proportions, a yellow and a blue powder, or yellow and blue paints. It is commonly imagined that the green colour which is thus produced is a mixture of blue and yellow. Far from it! When a disk divided into alternate sectors, coloured with the same blue and yellow pigments, is made to rotate rapidly in its own plane, it of course produces on the eye the true result of a mixture of these blue and yellow colours. This depends for its exact tint on the pigments employed, and on the angles of the sectors, but is usually a faint pink or a muddy purple,—utterly different from the green produced by mixing the powders or the paints. Helmholtz was the first to point out the true source of the green. It is the *one colour* which is not freely absorbed either by the yellow or by the blue pigment. For the scattered light by which the mixture is seen comes chiefly from below the surface, and has thus suffered absorption by each of the component powders. The yellow powder removes the greater part of the blue, indigo, and violet rays; the blue, the greater part of the reds, oranges, and yellows. Thus the light which finally escapes is mainly green.

For the accurate study of the absorptive power of a solid or liquid medium, it is necessary to compare the spectrum of white light which has passed through a plate or layer of it with a normal spectrum. This is easily effected by placing the absorbing medium (if a fluid, it must be in a

glass trough with parallel sides) in front of the narrow slit through which the light passes, and in such a position that one half of the slit only is thus covered. We have then side by side, under precisely similar circumstances, two spectra to be compared (one altered by absorption, the other not); and very minute differences between them can thus be detected. When the medium produces a general weakening of the whole spectrum, as well as particular local absorptions, the white light passing through the other half of the slit may be weakened to any desired extent by reflection at the proper incidence from a plate of glass, before it falls on the slit.

To give a satisfactory representation of the phenomena of absorption spectra by the help of a woodcut is not easy. The highest artistic skill could not adequately represent the ordinary solar spectrum by the use of the finest pigments. All optical colour phenomena must be *seen*, they cannot be reproduced by painting. In such circumstances the simplest method of indicating the locality and amount of the absorption is the best. As we have already seen that we cannot by the eye judge of the relative intensities of lights which differ much in colour, we shall represent the normal spectrum (for our present purpose) as equally bright throughout, and indicate the absorption at different parts by shading of various degrees of depth. A few of the Fraunhofer lines are introduced to indicate (in the absence of colour) the parts of the spectrum which are attacked by the various absorbents. These lines are, of course, in the same absolute positions in all the various spectra; for the spectra are all supposed to be given by the same prism. The line B is in the red, D in the orange, E and F in the green, and G in the indigo. They correspond, as we have already said, to perfectly definite kinds of homogeneous light, and therefore adequately represent the distribution of colours in the spectrum, however much irrationality of dispersion may be shown by the material of the prism.

In fig. 26  $\alpha$  represents the spectrum of light which has passed through diluted blood;  $\beta$  shows the spectrum when the blood has been acted on by a reducing agent; and  $\gamma$  the spectrum when the blood has been altered by acidulation with acetic or tartaric acid. These figures are taken from an important paper by Stokes (*Proceedings of the Royal Society*, 1864).

Fig. 27 shows in a rude way the absorption by cobalt

Fig. 26.

Fig. 27.

glass cut in wedge form, and corrected by an equal prism of clear glass.

The commonly received method of calculating the absorption by layers of gradually increasing thickness is to

suppose that, if a layer of unit thickness weakens in any ratio the intensity of any particular homogeneous ray, another unit layer will farther weaken in the same ratio that which reaches it, and so on. Thus the amount which passes through a number of layers diminishes in geometrical progression, while the number of layers increases in arithmetical progression. This is certainly true (neglecting the amount reflected), unless the *intensity* of the light have an effect on the percentage transmitted. And fig. 27 shows, in a very striking manner, the difference between similar terms of different geometric series, as the common ratio becomes less and less. This ratio is not much less than 1 for certain red and blue rays, is smaller for yellow, and is very small for the rest of the red, for orange, and for green. The latter colours are therefore rapidly got rid of with increasing thickness; then the yellow becomes too feeble to be seen; while, even after the blue becomes almost insensible, the specially favoured red rays are still transmitted in sufficient quantity to be observed.

If  $x$  be the fraction of any species of homogeneous light which is transmitted by a layer of unit thickness, that transmitted by a layer of thickness  $x$  is  $x^x$ . The following little table will greatly assist the reader in understanding the relative equality of extinction of different rays passing through various thicknesses of an absorbing medium. It is a table of double entries, the first column giving various values of  $x$ , and the upper row various values of  $x$ , while the value of  $x^x$  is in the same column as that of  $x$  and in the same row as that of  $x$ .

1	1	0.29	0.9	0.5	0.1
2	1	0.18	0.81	0.25	0.01
5	1	0.051	0.59	0.03	0.0001
10	1	0.004	0.14	0.0009	
100	1	0.0000	0.0000		

Thus a ray which loses 1 per cent. in unit thickness still preserves more than 99 per cent. after passing through ten units. But a ray which loses 10 per cent. in the first unit and which, therefore, will thus far appear scarcely more weakened than the first ray reduced to 35 per cent. by passage through ten units. After passing through a hundred units the first ray has lost only 63 per cent., the second is practically invisible.

In thin plates cobalt glass is blue, because the particular red which it does not absorb freely forms only a small fraction of the whole transmitted rays, while in thick masses it is nearly red, for then little but this favoured red is transmitted. For a similar reason Crody's fluid (permanganate of potash) changes its tint in a very singular manner (even when preserved from the action of the air) by gradual dilution with water.

The imperfection of the accommodation of the eye is readily proved by looking through a plate of cobalt glass at a small hole in the window-shutter of a dark room. The hole at first appears red with a blue space round it, but, by an effort of the muscles of the eye, we can see the hole blue, and then there is a red space surrounding it. Rays of so widely different refractive index cannot be seen in focus simultaneously.

Very curious effects are produced when we examine a landscape through such a glass. Foliage of certain kinds scatters scarcely any blue rays, and therefore appears reddish. Bluish green azarum, which scatter very little red, appear blue. The effects may be exaggerated in a very striking degree by combining the absorptions of two or more media, so as to allow of the free transmission of a few, far detached, portions of the spectrum.

Brewster made the very singular discovery that a solution of oxalate of chromium and potash produces one solitary, narrow, absorption band, almost resembling one of the broader lines in the solar spectrum.

Closely connected with intense local absorption in certain parts of the spectrum is the phenomenon of *abnormal dispersion*, one of the most singular discoveries of modern times. It seems to have been first observed by Fox

Talbot; and he discovered its real nature. But the first published notice of such phenomena is due to Le Roux. Christiansen and others have since greatly extended our knowledge of the subject, and Helmholtz and Ketteler have given theoretical explanations of it. Fox Talbot's experiment, though the earliest on record, is one of the easiest to perform, and we therefore quote his own account. The experiment was made about 1840, and the following account is from the *Proc. Roy. Soc. Edin.*, 1870 71.

**Talbot's experiment.** "I prepared some square pieces of window glass, about an inch square. Taking one of these, I placed upon it a drop of a strong solution of some salt of chromium, which, if I remember rightly, was the double oxalate of chromium and potash, but it may have been that substance more or less modified. By placing a second square of glass on the first, the drop was spread out in a thin film, but it was prevented from becoming too thin by four pellets of wax placed at the corners of the square, which likewise served to hold the two pieces of glass together. The glasses were then laid aside for some hours until crystals formed in the liquid. These were necessarily thin, since their thickness was limited by the interval between the glasses. Of course the central part of each crystal, except the smallest ones, was bounded by parallel plates, but the extremities were bevelled at various angles, forming so many little prisms; the smallest of them floating in the liquid. When a distant candle was viewed through these glasses, having the little prisms interposed, a great number of spectra became visible caused by the inclined edges. Most of these were no doubt very imperfect, but by trying the glasses at various points, one very distinct spectrum was obtained, and the result with some trouble isolated by covering the glass with a card pierced with a pin-hole. It was then seen that each prism or oblique edge of crystal produced two spectra oppositely polarized and well separated. One of these spectra was normal, that is, nothing particular about it. The colours of the other were very anomalous, and after many experiments, I came to the conclusion that they could only be explained by the supposition that the spectrum after proceeding for a certain distance, stopped short and did not appear at all."

**Iodine vapour.** Le Roux in 1860<sup>1</sup> discovered that vapour of iodine which allows only red and blue rays to pass, refracts red more than the blue. He, like Talbot, did not at first venture to publish his result, and it appeared only in 1862. Among the many convincing proofs of its accuracy he shows that the dispersion by an iodine-vapour prism can be nearly achromatized by a glass prism which gives refraction in the same direction. He also states that the dispersion in iodine vapour is less as the temperature is higher.

**Fuchsine.** Christiansen's<sup>2</sup> earliest determinations were made in 1870 upon an alcoholic solution of fuchsine (one of the powerful aniline colours). This solution gives a dark absorption band in the green; and it was found that the refractive index rises (as in normal bodies) for rays from the red to the yellow. But all the rest of the transmitted light, consisting of the so-called "more refrangible" rays, is less refracted than the red. Kundt and others shortly afterwards greatly extended these observations.

The explanation of this phenomenon, which has been advanced by Helmholtz,<sup>3</sup> depends upon an assumption as to the nature of the mutual action between the luminiferous ether and the particles of the absorbing medium, coupled with a further assumption connecting the absorption itself with a species of friction among the parts of each absorbing particle.

In 1879 De Klerker<sup>4</sup> made a very curious observation, which shows that the whole subject is still obscure. He employed two hollow prisms of equal angle, turned opposite ways, and filled with alcohol. Through such a combination light passes (as we have seen) without refraction or dispersion. When a few drops of the fuchsine solution were added to the contents of one of the prisms, the yellow, orange, and red rays (in the order named) began to separate themselves from the others. This process could be carried on until the solution was so strong that it transmitted no visible light. All this time the blue and violet

rays remained apparently unrefracted—the yellow, orange, and red showing continually increasing refraction. The conclusion from this, on either theory of light, is that the addition of fuchsine to alcohol alters the velocity of propagation of the (so-called) less refrangible rays, but not perceptibly that of the more refrangible.

**Fluorescence.**—The singular surface appearances presented by "canary" glass, by some specimens of fluor spar, and by certain liquids, such as a solution of sulphate of quinine acidulated with sulphuric acid, had been the source of much speculation long before their true nature was traced by Stokes in 1852.<sup>5</sup> By a series of well-contrived experiments, one or two of which will presently be described, he put it beyond doubt that the cause of these phenomena lies in a change of refrangibility of the light which has been absorbed by the upper layers of the medium, and then given off again. In every case the fluorescent light appears to belong to a less refrangible part of the spectrum than does the incident light which gave rise to it, thus affording an instance of dissipation, or degradation of energy.

The yellowish-green surface-colour of canary glass (coloured with oxide of uranium) is well known, as the substance is, mainly on account of this property, very commonly used for ornaments. If we admit a ray of sunlight (or light from the electric lamp) into a dark room, through a cobalt glass so dark that the feeble violet-coloured light it transmits is scarcely visible, we find that the canary glass shows its yellow-green colour vividly when placed in the track of the ray. Striking as this experiment is, it is not quite conclusive as to the true cause of the appearance. But if we take another piece of glass, slightly tinged of a brownish yellow (by oxide of gold), we find that it is quite transparent to the brilliant light from the canary glass; if, however, we place it in the track of the violet rays *before* they fall on the uranium glass, it prevents the production of the phenomenon altogether. That is, rays which cannot pass through the glass coloured with gold are rendered capable of freely passing through it after incidence on the canary glass. That the phenomenon is due to rays being stopped by the uranium glass itself is proved by the fact that a second piece of the glass, placed in the track of the rays which have passed through the first, does not show the phenomenon. Unless, indeed, the source of light be very bright, the appearance is confined to a mere surface-layer of the first piece of canary glass. The phenomenon is very well shown by an aqueous infusion of horse-chestnut bark. Some specimens of paraffin oil exhibit it most brilliantly.

To find the rays which are most effective in producing the fluorescence of any substance, we have only to place it in a pure spectrum of sunlight, (or, preferably, of the electric light),—prisms and lenses of quartz being used for producing the spectrum, because that material is found to be far less opaque than glass is to the violet and ultra-violet rays. When this is done with uranium glass we find scarcely a trace of effect until the substance reaches the blue rays, and the effect persists through all the higher colours, and even very considerably beyond the bounds of the visible spectrum. Stokes in fact used it as a means of studying the otherwise invisible, but far extending, spectrum of the ultra-violet rays of the electric spark.

The mechanism of the process by which these extraordinary results are produced is still somewhat obscure, and we cannot attempt to explain it here.

The duration of fluorescence is so very short that it is only by specially devised methods that we can make certain that it persists for any measurable time after the exciting

light is cut off from the fluorescent body. Becquerel's ingenious *phosphoroscope* was invented for the purpose of inquiries of this kind. It consists essentially of a shallow drum, in whose ends two excentric holes, exactly opposite to one another, are cut. Inside it are fixed two equal metal disks, attached perpendicularly to an axis, and divided into the same number of sectors, the alternate sectors of each being cut out. One of these disks is close to one end of the drum, the other to the opposite end, and the sectors are so arranged that, when the disks are made to rotate, the hole in one end is open while that in the other is closed, and *vice versa*. If the eye be placed near one hole, and a ray of sunlight be admitted by the other, it is obvious that while the sun shines on an object inside the drum the aperture next the eye is closed, and *vice versa*. If the disks be made to revolve with great velocity by means of a train of toothed wheels, the object will be presented to the eye almost instantly after it has been exposed to sunlight; and these presentations succeed one another so rapidly as to produce a sense of continued vision. By means of this apparatus we can test with considerable accuracy the duration of the phenomenon after the light has been cut off. For such a purpose we require merely to know the number of sectors in the disks and the rate at which they are turned. To guard against deception by the persistence of impressions on the retina, the eye should not be directed fixedly on the object, but should be kept travelling slowly round the position in which it is seen to lie.

Uranium glass shows, with rapid turning, nearly as vivid an effect as when exposed to continuous light, but fades rapidly when the speed of the rotation falls off. A pinkish kind of ruby, exposed to concentrated sunlight in the phosphoroscope, is seen to glow with a bright red like a piece of live coal. With very rapid turning, feeble fluorescence can be detected in a great many substances in which the ordinary methods will not show it. This is due in great measure to the fact that the phosphoroscope entirely does away with the scattered light, which in the ordinary mode of examining these substances overpowers their feeble fluorescence.

What is correctly termed phosphorescence has nothing to do with phosphorus (whose luminosity in the dark is due to slow oxidation), but it is merely a species of fluorescence which lasts for a much longer time after the excitation has ceased than does that just described. Pliny speaks of various gems which shine with a light of their own, and Albertus Magnus knew that the diamond becomes phosphorescent when moderately heated. But the first discovery of phosphorescent substance—such as are now so common, belongs to the early part of the 17th century. During that century the Bologna stone (sulphide of barium) and Homberg's phosphorus (chloride of calcium) were discovered. Canton's phosphorus (sulphide of calcium) dates from 1768. To the substances mentioned may now be added sulphide of strontium. Any of these sulphides, which must be carefully preserved from the air in sealed glass tubes, appears brilliantly luminous when carried from sunlight into a dark room, and for a long time after presents the general aspect of a hot body cooling. The rays which excite their luminosity are (as with the generality of fluorescent bodies) those of higher refrangibilities; but the colours of the phosphorescent light are of the most varied kind, even in specimens of almost precisely the same chemical composition, but prepared at different times. The causes of this strange diversity are as yet quite unguessed at; but the property has been taken advantage of for the production of what are called *luminous paints*. The behaviour of these substances is one of the most singular phenomena in optics. How they manage to store up so large a supply of energy during a short exposure to bright

light, and to dole it out continuously for so long a time and mainly in the form of light, is exceedingly puzzling, especially as no other physical or chemical change has yet been found to accompany the process. Another curious fact connected with their behaviour was discovered by Becquerel. He found that the less refrangible rays have in some cases the power of arresting the emission of light from these bodies when they have been previously excited by higher rays.

The chemical effects of light will be treated under PHOTOCHEMISTRY so far as they are connected with decomposition. Its effects in causing combination, as of hydrogen and chlorine, have already been treated under CHEMISTRY.

### UNDULATORY THEORY OF LIGHT

The explanation of the fundamental laws of Geometrical Optics by the wave theory requires some preliminary remarks. As the subject will be more fully discussed in a special article, we confine ourselves to what is strictly necessary for the immediate purposes of the present article.

(a) The essential character of wave motion is that a Wave-disturbance of some kind is added each in one portion of motion, a solid or fluid mass is set in motion, and moves only, this disturbance is unaltered in any and in kind as it proceeds.

(b) So far as light is concerned, the disturbance is each particular portion of disturbance, and it is the same for all directions. When the medium is isotropic, the velocity may vary from point to point. If the medium be not isotropic, the velocity of propagation is different in different directions. Example: double refraction. These peculiarities will be met with presently.

(c) When two or more separate disturbances are present, they only affect the same portion of a medium, and may be very complex. But, in the case of light, it has been found that a geometrical (or rather a physical) law of superposition or composition applies, at least to the results of the experiment, with all the accuracy that could be expected, as a dynamical law. The disturbance due to wave motion were always a periodic function of time, and of position. On the doctrine of *interference*, see below. Young's experiments confirm the wave theory (1801).

(d) The disturbance at any point and instant, is the due to the superposition of all the disturbances which are at that point at that instant, and the surrounding portions of the medium. The principle (in a somewhat generalized form) what is commonly called Huygen's principle, first enunciated in 1686.

(e) The *front* of a wave is defined at any instant as the Wave-continuous locus of all portions of the medium which, at that instant, are equally and uniformly disturbed. The word *contour* is inserted because, in oscillatory wave motion, such as that of light, a large number of successsive waves are exactly equal and similar to one another. Thus we have a *series* of wave-fronts following one another, which are not to be considered as parts of one wave-front. The distance between two successive fronts in which the distortions are similar, measured in the direction in which the light is travelling, is called the *wave length*.

(f) The *colour* of homogeneous light depends entirely on colour, the *period* of a wave, i.e., on the time of passage from one wave-front to the next. This is obviously the same thing as the time of a complete vibration of any one particle of the medium—whatever be the velocity of light in the medium, or the consequent wave length.

These being premised, let us take the propagation of homogeneous light from a luminous point in a homo-

Phosphorescence.

Luminous paint.

Wave-motion in homogeneous isotropic medium.

geneous isotropic medium. Here we have simply a succession of concentric spherical wave-fronts, their radii differing by one or more whole wave-lengths. The disturbance in any portion of one of these fronts is propagated radially. But we may consider it from a different point of view, as hinted in (d) above. Simple as this particular case is, the reader will probably find that it will greatly assist him in understanding the more complex ones which follow.

Every disturbed portion of the medium may be looked upon as a centre of disturbance from which a new set of spherical waves is constantly spreading. Take then, as common radius, the space described by a disturbance in any very short interval; and, with centres at every point of any one wave-front, describe a series of spheres. The ultimate intersections of these spheres will lie on a surface which is the *envelop* of them all. In the case considered, it is obviously a sphere whose radius exceeds that of the wave-front from which we started by the common radius of the set of spheres. This is shown in a central section in fig. 28 below, which suffices to prove that we arrive by this mode of construction at the result which we know in this simple case to be the correct one. It will be seen that the centres of the construction-spheres lie on a certain part of one wave-front, while their ultimate intersections lie on the corresponding part of the future wave-front. This holds for spheres of all radii, and for continually increasing radii shows that a plane wave moves perpendicularly to its front. This is so important a part of Huygens's work that we give it in his own words (*Traité de la Lumière*, 1690, pp. 18-20):—

"Pour venir aux propriétés de la lumière : remarquons premièrement que chaque partie d'où se doit étendre en sorte, que les extrémités soient toujours comprises entre les mêmes lignes droites tirées du point lumineux. Ainsi la partie de l'onde BG, ayant le point lumineux A pour centre, s'étendra en l'arc CE, terminée par les droites ABC, AGE. Car bien que les ondes particulières, produites par les particules qui remplissent l'espace CAE, se répandent aussi hors de cet espace, toutefois elles ne concourent point en même instant, à composer ensemble une onde qui termine le mouvement, que précèdent dans la circonférence CE, qui est la tangente commune.

"Et d'où l'on voit la raison pourquoi la lumière, à moins que ses rayons ne soient réfléchis ou rompus, ne se répand que par des lignes droites, en sorte qu'elle n'éclaire aucun objet que quand le chemin depuis la source jusqu'à cet objet est ouvert suivant des lignes.

Car si, par exemple, il y avoit une ouverture BG, bornée par des corps opaques BH, GI; l'onde de lumière qui sort du point A sera toujours terminée par les droites AC, AE, comme il vient d'être démontré : les parties des ondes particulières, qui s'étendent hors de l'espace ACE, étant trop faibles pour y produire de la lumière.

"Or quelque petite que nous fassions l'ouverture BG, la raison est toujours la même pour y faire passer la lumière entre des lignes droites : parce que cette ouverture est toujours assez grande pour contenir un grand nombre de particules de la matière éthérée, qui sont d'une petite étendue, et par conséquent de sorte qu'il paroît que chaque petite partie s'avance nécessairement suivant la ligne droite qui vient du point lumineux. Et c'est ainsi que l'on peut prendre des rayons de lumière comme si c'étoient des lignes droites.

"Il paroît au reste, par ce qui a été remarqué touchant la faiblesse des ondes particulières, qu'il n'est pas nécessaire que toutes les particules de l'éther concourent entre elles, quoique l'égalité soit plus propre à la propagation du mouvement. Car il est vrai que l'inégalité fera qu'une particule, en poussant une autre plus grande, fasse effort pour reculer vers une partie de son mouvement, mais il ne s'engendrera de cela que quelques ondes particulières en arrière vers le point lumineux, incapables de faire de la lumière : & non pas d'onde composée de plusieurs, comme étoit CE.

"Une autre, et des plus merveilleuses propriétés de la lumière est que, quand il en vient de divers costez, ou même d'opposés, elles

font leur effet l'une à travers l'autre sans aucun empêchement. D'où vient aussi que par une même ouverture plusieurs spectateurs peuvent voir tout à la fois des objets différens, et que deux personnes se voyent en même instant les yeux l'un de l'autre. Or suivant ce qui a été expliqué de l'action de la lumière, et comment ses ondes ne se détruisent point, ny ne s'interrompent les unes les autres quand elles se croisent, ces effets que je viens de dire sont aisé à concevoir. Qui ne le sont nullement à mon avis selon l'opinion de Des-Cartes, qui fait consister la lumière dans une pression continuelle, qui ne fait que tendre au mouvement. Car cette pression ne pouvant agir tout à la fois des deux costez opposés, contre des corps qui n'ont aucune inclination à s'approcher; il est impossible de comprendre ce que je viens de dire de deux personnes qui se voyent les yeux mutuellement, ni comment deux flambeaux se puissent éclairer l'un l'autre."

We will now, for the purposes of this elementary article, assume that something similar holds in all cases, and will not trouble ourselves with the fact that our construction, if fully carried out, would indicate a retrograding wave as well as a progressive one. The obvious fact that a solitary wave can be propagated in water, or along a stretched string, may assist the reader in taking the bold step which we have proposed to him. And we will also assume that this mode of representation leads to correct results even when we do not choose a wave-front as the locus of the centres of disturbance,—that in fact we may choose for our purpose any surface through which the rays pass, provided always that the radii of the spheres are so chosen that the length of each ray, from some definite wave-front to the centre of the sphere, together with the radius of that sphere, always corresponds to a path described in a given time.

We are now prepared to explain the reflexion of light, and we need do so for a plane reflecting surface alone, because the length of a wave, as we shall soon see, is an almost vanishing quantity in comparison with the radius of curvature of any artificial mirror, be it even the smallest visible drop of mercury.

Let a plane wave front be approaching a plane mirror, and at any instant let fig. 29 represent a section by a plane perpendicular to each, cutting the wave-front in AB, and the mirror in AC. From what has been already said, the motion of every part of AB is perpendicular to that line, and in the plane of the figure. During the time that the disturbance at B takes to reach C, the disturbance which had reached A will have (in part, for there is usually a refracted part also) spread back into the medium in the form of a spherical wave whose radius, AD, is equal to

Fig. 28.

Fig. 29.

its section is of course a circle. That from any other point, P will have reached Q, and then (in part) diverged into a spherical wave whose centre is Q and radius QT (= QT) = BC - PQ. Obviously all the circles which can be thus drawn ultimately intersect in the straight line CD. This is a section of the reflected wave-front. A plane wave, therefore, remains a plane wave after reflexion, each part of it obviously moves in the plane of incidence, and the similarity of the triangles ABC and CDA proves the equality of the angles of incidence and reflexion, for the ray is everywhere perpendicular to the wave-front. It is to be particularly noted that this is independent of the velocity of the light, so that all rays are reflected alike. In this, as in the preceding and the immediately following instances, the diagram has been taken (with but slight change) from Huygens.

This being true of any plane wave-front, large or small in area, is necessarily also true of any wave-front of finite

curvature. Thus, if a set of rays be drawn perpendicular to any wave-front, they will after reflexion be perpendicular to a new wave-front; and the lengths of all the rays, from wave-front to wave-front, will be equal.

This is merely another way of stating that if a set of rays can be cut at right angles by a surface (of finite curvature) they will always be capable of being cut at right angles by such a surface, even after any number of reflexions at surfaces of finite curvature, provided they move in a homogeneous isotropic medium.

**Usual explanation of refraction.** This proposition will be seen to be capable of extension to refraction, provided always that both media are homogeneous and isotropic. For a plane wave, falling on a plane refracting surface, our construction (fig. 30) is as follows:—

Let AB be, as before, a plane wave front in the first medium, and AC the plane surface of the second medium. As before, let BC be perpendicular to AB. Also let CD' be drawn parallel to BA. With centre A and radius AD equal to the space described in the second medium while BC is described in the first, let a sphere be described. The disturbance at A will have diverged in this sphere, while that at B has just reached C. The disturbance at any other point, as P, will have passed to Q, and then have diverged into a sphere of radius QT such that

FIG. 30.

$$QT : QT' :: AD : BC.$$

Obviously all spheres so drawn ultimately intersect along CD, which is therefore the front of the refracted wave. The angles of incidence and refraction, being the inclinations of the incident and refracted rays to the normal, are the inclinations BAC and DCA of the incident and refracted wave-fronts to the refracting surface. Their sines are evidently in the ratio of BC to AD, i.e., they are directly as the velocities of propagation in the two media.

Hence the law of refraction also follows from this hypothesis. But there will now be separation of the various homogeneous rays, because the ratio of their velocities in the two media is not generally constant.

Besides, it is clear from the investigation above that, in the refracting medium, the rays are still perpendicular to the wave-front. Thus the proposition lately given may now be extended in the following form:—

If a series of rays travelling in homogeneous isotropic media be at any place normal to a wave-front, they will possess the same property after any number of reflexions and refractions. And it is clear from the investigations already given that the time employed by light in passing from one of these wave-fronts to another is the same for every ray of the series.

**Test of theory.** We now see how crucial a test of theory is furnished by the simple refraction of light. On the corpuscular theory the velocity of light in water is to its velocity in air as 4 : 3 nearly; on the undulatory theory these velocities are as 3 : 4, since, as we have seen, the refractive index of water is about  $\frac{4}{3}$ . But Foucault's experimental method showed at once that the velocity is less in water than in air. This finally disposed of the corpuscular theory. Though it had been conclusively disproved long before, by certain interference experiments whose nature will presently be described, the argument from these was somewhat indirect and not well suited to convince the large non-mathematical class among optical students and experimenters. The true author of the undulatory theory is

undoubtedly Huygens. Grimaldi, Hooke, and others had expressed more or less obscure notions on the subject, but Huygens in 1678 first gave it in a definite form, based to a great extent upon measurements of his own. It was read to the French Academy, but not published till 1690, when it appeared with the title *Traité de la Lumière*. Huygens gives the explanation of the double refraction of Iceland spar, which had been described by Bartholinus in 1670. Unfortunately the remarkable step taken by Newton in explaining the law of refraction on the corpuscular theory—the earliest solution of a problem connected with molecular forces—had for some time been before the scientific world. The authority of Newton was paramount, in such matters, and the work of Huygens produced no effect at the time. Even the genius of Young, who at the commencement of the present century recalled attention to this all-but forgotten theory, and enriched it by the addition of the principle of interference, as well as by many important applications, failed to secure its recognition.

It was not till 1815 and subsequent year that, in the hands of Fresnel, the undulatory theory finally triumphed, and, even then, the battle was won against determined resistance on the part of the upholders of the corpuscular theory. Witness what Laplace said, in 1817, in the following excerpt from a letter to Young:—

"J'ai reçu la lettre que vous m'avez fait l'honneur de m'écrire, et dans laquelle vous cherchez à établir que, suivant le système des ondulations de la lumière, les sines d'incidence et de réflexion sont en rapport constant, lorsque le passage d'un milieu dans un autre. Quelque ingénieux que soit ce raisonnement, je ne puis le regarder que comme un aperçu, et non comme une démonstration géométrique. Je persiste à croire que le problème de la propagation des ondes, lorsqu'elles traversent différents milieux, n'a jamais été résolu, et qu'il surpasse peut-être les forces actuelles de l'analyse. Descartes expliquait ce rapport constant, au moyen de deux suppositions; l'une, que la vitesse des rayons lumineux perpendiculairement à la surface du milieu réfringent ne change d'un point par l'autre; l'autre, que sa vitesse entière dans ce milieu était la même, sous toutes les incidences; mais comme il ne faut point admettre de suppositions aux lois de la mécanique, son explication est évidemment combattue et rejetée par les plus grands et les plus habiles physiciens jusqu'à ce que Newton ait fait voir que ces suppositions résultaient de l'action du milieu réfringent sur la lumière; mais on a eu une explication mathématique du phénomène dans le système de l'émission de la lumière; système qui donne en outre l'explication la plus simple du phénomène de l'absorption, que nul autre point le système des ondes lumineuses. Avec les suppositions de Descartes, comme plusieurs aperçus de Kepler sur le système du monde, ont été vérifiées par l'analyse; mais le monde de la découverte d'une vérité appartient tout entier à celui qui l'a découvert. Je conviens que de nouveaux phénomènes de la lumière ont été présentés très difficilement à l'explication; mais en les étudiant avec un grand soin, pour découvrir les lois dont ils dépendent, on peut être parvenu un jour à reconnaître dans les molécules lumineuses des propriétés nouvelles qui donneront une explication mathématique de ces phénomènes. Remonter des phénomènes aux lois et des lois aux forces, est, comme vous le savez, la voie normale des sciences naturelles."

Poggendorff remarks that there is no other instance, in the whole history of modern physics, in which the truth was so long kept down by authority. Poggendorff further remarks that of the six chief phenomena of light known in Huygens's time he fully explained three—reflexion, refraction, and the double refraction of Iceland spar—at least so far as concerns the direction of the reflected or refracted rays. Phenomena such as diffraction, and the colours of thin plates, required the principle of interference for their explanation: which was first given by Young; and dispersion (not yet quite satisfactorily disposed of) was first accounted for in comparatively recent times by Cauchy. Huygens himself was the discoverer of polarization, but he could not account for it. Even Young also, because like Huygens he supposed the undulations to be in the direction of the ray, failed to account for it; and it was not explained till Fresnel reintroduced with the

<sup>1</sup> Young's Works, ed. by Peacock, vol. 3, p. 374. It is matter for curious remark that Laplace refers to Des. cartes only, and not to Huygens.

Opposition to the undulatory theory.

most brilliant success a guess of Hooke's (of date 1672), that the vibrations of light in an isotropic medium are *perpendicular* to the direction of the ray.

Classes  
of waves.

Taking the undulatory theory as the only one left possible by the experiments of Foucault, we will now consider the explanation it offers of various phenomena. It will be remembered that *we have as yet made no assumption whatever as to the precise nature of a wave*; and it will be found that a large class of important phenomena can be explained by it without our making any such assumption, but that other classes of phenomena compel us to adopt certain limitations of the very general hypothesis with which we started. As long as we deal with the first class of phenomena, we may take for granted those properties which are common to all ordinary forms of wave-motion, such as those in water or air. In ordinary water-waves the motion of a particle is partly to and fro in the direction in which a wave is travelling, partly up and down and therefore perpendicular to that direction. This is obvious to every one who watches a floating cork. In sound-waves, whether in air or in water, the displacement of each particle of the medium is wholly in the direction in which the wave is travelling. Directly connected with this there is another distinction between these classes of waves. In ordinary water-waves the water elements change only their *form* as the wave passes; in sound waves there is change of *volume* also. A third distinction, also directly connected with the first, is that sound waves in water travel at a much greater rate than the swiftest, *i.e.*, the longest, of surface waves.

Inter-  
ference.

But, in either case, when two similar and equal series of waves arrive at a common point they *interfere*, as it is called, with one another, so that the actual disturbance of the medium at any instant is the resultant of the disturbances which it would have suffered at that instant from the two series separately. Thus if crests, and therefore troughs, arrive simultaneously from the two series, the result is a doubled amount of disturbance. If, on the contrary, a crest of the first series arrive along with a trough of the second, the next trough of the first series will arrive along with the next crest of the second, and so on. One series is then said to be half a wave-length behind the other. In this case, the portion of the medium considered will remain undisturbed. Thus, at the port of Batsha in Tong King, the ocean tide wave arrives by two different channels, one part being nearly six hours, or half a wave-length, behind the other. As a result, there is scarcely any noticeable tide at Batsha itself, though at places not very far from it the rise and fall are considerable. This was known to Newton, and is noticed by him in the *Principia*, iii. 24. See also *Phil. Trans.*, vol. xiv. p. 677, for the observed facts and Halley's comments. Thus also (see Acoustics) two sounds of the same wave-length and of equal intensity produce silence if they reach the external ear with an interval of half a wave-length, or any odd multiple of half a wave-length.

Tides of  
Batsha.

Young's  
dis-  
covery.

It is not remarkable that Young's Bakerian Lecture (1801), in which the principle of interference is for the first time described and applied, should consist in great part of extracts from the *Principia*. For there are many passages in Newton's works which might have been written by an upholder of the wave theory. Unaccountably, however, Newton in the context almost always brings in a reference to the "rays of light" as something different from the vibrations of the ether, yet capable of being acted on by them so as to be put into "fit of easy reflexion or of easy transmission." These allusions are the most obscure parts of all Newton's scientific writings; and it is very difficult to form a precise conception of what he meant to express in them.

The following passage, extracted from Young's temperate

reply (*Works*, vol. i. p. 202) to the violent but ignorant assault on him by Lord Brougham in the *Edinburgh Review*, is chosen as showing his own estimate of his own work and of its relation to what was already known:—

"It was in May 1801 that I discovered, by reflecting on the beautiful experiments of Newton, a law which appears to me to account for a greater variety of interesting phenomena than any other optical principle that has yet been made known. I shall endeavour to explain this law by a comparison. —

"Suppose a number of equal waves of water to move upon the surface of a stagnant lake, with a certain constant velocity, and to enter a narrow channel leading out of the lake. Suppose then another similar cause to have excited another equal series of waves, which arrive at the same channel, with the same velocity, and at the same time with the first. Neither series of waves will destroy the other, but their effects will be combined: if they enter the channel in such a manner that the elevations of one series coincide with those of the other, they must together produce a series of greater joint elevations; but if the elevations of one series are so situated as to correspond to the depressions of the other, they must exactly fill up those depressions, and the surface of the water must remain smooth; at least I can discover no alternative, either from theory or from experiment.

"Now I maintain that similar effects take place whenever two portions of light are thus mixed; and this I call the general law of the interference of light. I have shown that this law agrees, most exactly, with the measures recorded in Newton's *Optics*, relative to the colours of transparent substances, observed under circumstances which had never before been subjected to calculation, and with a great diversity of other experiments never before explained. The *l'assort*, as a most powerful argument in favour of the theory which I had before revivied: there was nothing that could have led me in any other way with whom I am acquainted, except some effect hints in those inexhaustible but neglected mines of out-invention: the works of the great Dr Robert Hooke, which had not occurred to me at the time that I discovered the law; and except the Newtonian explanation of the combinations of tides in the port of Batsha."

Young's first application of the principle of interference was made to the colours of *striated surfaces*, the next to the colours of *thin plates*. These, however, are not so easily intelligible as the application to an experiment devised by Fresnel several years later. We therefore commence with Fresnel's experiment, which gives the most simple arrangement yet contrived, but it must be understood that the explanation is really due to Young. BCD (fig. 31) is an isosceles prism of glass, with the angle at C very little less than two right angles. A luminous point is

Inter-  
ference  
experi-  
ments.

Fig. 31.

placed at O, in the plane through the obtuse edge of the prism and perpendicular to its base. If homogeneous light be used, the light which passes through the prism will consist of two parts, diverging as if from points O<sub>1</sub> and O<sub>2</sub>, symmetrically situated on opposite sides of the line CO. Suppose a sheet of paper to be placed at A with its plane perpendicular to the line OCA, and let us consider what illumination will be produced at different parts of this paper. As O<sub>1</sub> and O<sub>2</sub> are images of O, crests of waves must be supposed to start from them simultaneously. Hence they will arrive simultaneously at A, which is equidistant from them, and there they will reinforce one another. Thus there will be a bright band on the paper parallel to the edges of the prism. If P<sub>1</sub> be chosen so that the difference between P<sub>1</sub>O<sub>2</sub> and P<sub>1</sub>O<sub>1</sub> is half a wave-length (*i.e.*, half the distance between two successive crests), the two streams of light will constantly meet in such relative conditions as to destroy one another. Hence there will be a line of darkness on the paper, through P<sub>1</sub>, parallel to the edges of the prism. At P<sub>2</sub>, where O<sub>2</sub>P<sub>2</sub> exceeds O<sub>1</sub>P<sub>2</sub> by a whole wave-length, we have another

Fringes  
in homo-  
geneous  
light.

bright band; and at  $P_2$ , where  $O_2P_2$  exceeds  $O_1P_1$  by a wave-length and a half, another dark band; and so on. Hence, as everything is symmetrical about the bright band through A, the screen will be illuminated by a series of bright and dark bands, gradually shading into one another. If the paper screen be moved parallel to itself or from the prism, the locus of all the successive positions of any one band will (by the nature of the curve) obviously be an hyperbola whose foci are  $O_1$  and  $O_2$ . Thus the interval between any two bands will increase in a more rapid ratio than does the distance of the screen from the source of light. But the intensity of the bright bands diminishes rapidly as the screen moves farther off; so that, in order to measure their distance from A, it is better to substitute the eye (furnished with a convex lens) for the screen. If we thus measure the distance  $AP_1$  between A and the nearest bright band, measure also  $AO$ , and calculate (from the known material and form of the prism, and the distance CO) the distance  $O_1O_2$ , it is obvious that we can deduce from them the lengths of  $O_1P_1$  and  $O_2P_2$ . Their difference is the length of a wave of the homogeneous light experimented with. Though this is not the method actually employed for the purpose (as it admits of little precision), it has been thus fully explained here because it shows in a very simple way the possibility of measuring a wave-length.

Measure of wave-lengths.

Effect of white light.

The difference between  $O_1P_1$  and  $O_2P_1$  becomes greater as  $AP_1$  is greater. Thus it is clear that the bands are more widely separated the longer the wave-length of the homogeneous light employed. Hence when we use white light, and thus have systems of bands of every visible wave-length superposed, the band A will be red at its edges, the next bright bands will be blue at their inner edges and red at their outer edges. But, after a few bands are passed, the bright bands due to one kind of light will gradually fill up the dark bands due to another; so that, while we may count hundreds of successive bright and dark bars when homogeneous light is used, with white light the bars become gradually less and less defined as they are farther from A, and finally merge into an almost uniform white illumination of the screen.

In this example, and in all others of a similar character which will be introduced into this elementary article, the solution is only *approximate*. The utmost resources of mathematics are in most cases required for the purpose of complete solution.

Additional proof that light moves slower in glass than in air.

We are now in a position to prove that light moves slower in glass than in air, by the process which was merely indicated while we were discussing the velocity of light. For, if we could slightly lengthen the paths of the rays which come from  $O_1$ , leaving those from  $O_2$  unaltered, the system of bands would obviously be shifted in the direction from A to P in the figure. This happens if a very thin film of glass be interposed in the path of the rays which appear to come from  $O_1$ . The best mode of making the experiment is to put a piece of very uniform plate glass, cut into two parts, between the prism and the screen, so that rays from  $O_1$  pass through one part and those from  $O_2$  through the other. So long as these pieces are parallel, no shifting takes place. But if one be slightly turned, so as to give the rays a longer path through it, the system of bands is at once displaced to the side at which it is situated.

Also, we can now see how it is possible to discover whether light has its velocity affected by that of the medium in which it is travelling. We know that sound travels faster with the wind, and slower against it, than it does in still air. We may, therefore, suppose a disposition of the interference apparatus such that the two rays which interfere have each passed through a long tube full of water. A rapid current may be established, in either

direction, in one or other of the tubes, or in opposite directions in the two, and the shifting of the interference bands will at once indicate the nature of the effect. We cannot describe the details of the process. The result, however, is analogous to that of wind on sound, but of course very much smaller; and it seems that the actual change of the velocity of light is less than the velocity of the current. See ERNIE.

Let us next consider the effect of a *grating*, a series of inter-fine parallel wires placed at small equal intervals, or a fence of equidistant parallel lines have been ruled by a diamond point. We take only the case in which plane waves of homogeneous light are incident in a direction perpendicular to the plane of the grating, and when the bars and openings of the grating are all equal in breadth.

Consider the effect on an eye or screen at a considerable distance, in the direction BE (fig. 32). If there were no grating, practically no light would reach the eye from the aperture AD unless ABE were very nearly a right angle.

FIG. 32

This is, of course, the statement of Huygens already quoted. But Young's principle enables us to see how this is the case. Let us divide AD into a series of equal parts by lines perpendicular to BE, and distant from one another by half a wave-length of the homogeneous light employed. The portions coming to the eye from any two adjacent parts AB, BC will be practically of the same intensity, and will exactly neutralize one another's effect on the eye. For if we take points *a* and *b* similarly situated with regard to A and B respectively, the distance of *a* and *b* from the eye differ by half a wave-length, and rays from *a* neutralize those from *b*. This is true whenever *a* be taken between A and B. Hence, under the conditions named, no light reaches the eye.

Now suppose the alternate parts AB, CD, &c., to be opaque. Similar reasoning will show that the remaining rays conspire to strengthen one another. Thus when homogeneous light from a distant point falls perpendicularly on a grating in which the breadth of the bars is equal to that of the interstices, it will be seen broadly in a direction inclined at an angle  $\theta$  (ABE) to the plane of the grating, the angle  $\theta$  being such that

$$AB \sin \theta = \text{wave-length}.$$

Similar reasoning shows that the light is reinforced whenever  $\theta$  is such that

$$AB \sin \theta = n\lambda$$

is an integral multiple of the wave-length. The appearance presented when a long narrow slit is the luminous object, and the bars of the grating are placed parallel to it, is therefore (with homogeneous light) a central image with others equidistant from it on each side, their angular distances from it being the values of the angle corresponding to the sines

$$\frac{\lambda}{a}, \frac{2\lambda}{a}, \frac{3\lambda}{a}, \&c.,$$

Here  $\lambda$  is the wave-length, and  $a$  is the sum of the breadths of a bar and an interstice. It is found in practice, and it is also deducible from the complete

theory, that the ratio of the breadths of the bar and interstice has but little effect on the result, unless it be either very large or very small. Hence if  $\lambda$  be expressed as a fraction of an inch, and  $n$  be the number of lines per inch in the grating, the angular deviations of the bright bands have the sines

$$n\lambda, 2n\lambda, 3n\lambda, \&c.$$

The mean wave-length of visible rays in air is about  $\frac{1}{50000}$ th of an inch. Thus a grating with 5000 equidistant lines per inch will give with such light an angular deviation of about 6° for the first bright diffraction line.

If we notice that the sine of the deviation is proportional to the wave-length, it will be obvious that when white light is used the result will be a series of spectra on each side of the central white image, their more refrangible ends being turned towards that image. When the grating is a very regular one, and the appearances are examined by means of a telescope adjusted for parallel rays, the spectra formed in this way show the Fraunhofer lines with as great perfection as do the best prisms. And they have one special advantage, which prisms do not possess. The relative angular separation of the various colours depends solely on their wave-lengths, and thus the spectra formed by different gratings are practically similar to one another. There is, in fact, almost no *irradiation* in this kind of dispersion. In glass prisms and especially in those of flint glass, the more refrangible part of the spectrum is much dilated, while the less refrangible part is compressed.

The counting of the number of lines per inch in a grating is not difficult, nor is the accurate measurement of the angle of deviation of any particular Fraunhofer line. Hence, by the help of the very simple formula given above, the wave-lengths of light corresponding to the various Fraunhofer lines have been determined with very great accuracy from the diffraction spectra of gratings. The following are, according to Angstrom,<sup>1</sup> a few of the chief values.  $\lambda$  is expressed in ten millionths of a millimetre.<sup>2</sup>

A	Atmospheric	7601	
B	Atmospheric	6867	
C	Hydrogen	6562	1.3317
D (double)	Sodium	5895	1.3336
E	Helium and Ir	5889	
F	Hydrogen	4861	1.3358
G	Ir	4307	1.3113
H (double)	Calcium and Iron	3968	1.3442
		3933	

For the sake of a discussion to be entered on later, we have appended the refractive index from air into water for each of these rays, as given by Fraunhofer himself.<sup>3</sup>

If now we suppose AB, CD, &c., to be transparent, while BC, &c., become opaque, it is obvious that the new grating will be the complement of the old one, and will give precisely the same appearances at points outside the course of the direct beam. For when there is no grating there is practically no illumination at such points. This statement of course is equally true of any grating, whatever be the ratio of the breadths of the bars to those of the interstices.

Another very curious result of the theory of interference, fully verified by experiment, is furnished by the fact that the central spot of the shadow of a small circular disk, cast by rays diverging from a distant point in its axis, is as brightly illuminated as if the disk had not been interposed.

The final example of interference which we can give here is noteworthy on account of a peculiarity which it

presents. Let us consider the case of homogeneous light reflected by a thin plate or film of a transparent material.

Let AB (fig. 33) be the direction of the incident ray, BzE the direction in which part of it is reflected to an eye E at a considerable distance; and let DE be the direction in which another part escapes after refraction into the plate at B and partial reflexion at the second surface of the plate at C. Then if Dd be drawn perpendicular to BE, the retardation of the wave in DE as compared with that in BE will be  $(2\mu BC - Bd)/\lambda$  wave-lengths, where  $\mu$  is the refractive index into the plate.

Fig. 33.

If  $a'$  be the angle of refraction, and  $t$  the thickness of the plate, it is easily seen that

$$BC \cos a' = t,$$

and  $BD = 2BC \sin a' = 2t \tan a'.$

Hence  $2\mu BC - Bd = 2\mu t \cos a'.$

Hence whenever, for a given thickness of plate,  $a'$  is such that

$$2\mu t \cos a'$$

is an integral multiple of  $\lambda$ , the two rays should reinforce one another at E. The same will happen for a given angle of incidence when the thickness of the plate is such that

$$2\mu t \cos a'$$

is an integral multiple of  $\lambda$ . When, on either account,  $2\mu t \cos a'$  is an odd integral multiple of  $\lambda/2$ ; the rays at E will weaken (perhaps destroy) one another.

Hence, in homogeneous light, a thin plate, turned about, alternately reflects and does not reflect to an eye in a given position. And a fixed plate of non-uniform thickness reflects light from some parts and not from others. When white light is used there will in general be colours seen which vary with the angle of incidence, and also with the thickness. If the plate is infinitely thin it would appear that there should be infinitely slight retardation only, and the plate should thus be bright in homogeneous light (and of course white in white light) at all incidences.

In general this is not the case. Thus when a soap bubble, or a vertical soap-film, is screened from currents of air, and allowed to drain, the uppermost (i.e., the thinnest) part becomes perfectly black. It can, in fact, be seen only by the feeble light scattered by little drops of oil or particles of soap or dust on its surface. Here, again, Young's sagacity supplied the germ at least of the explanation. It is given in the following extract from his *Theory of Light and Colours*, the Bakerian Lecture for 1801 already referred to:—

"PROPOSITION IV.—When an undulation arrives at a Surface *less of which is the Limit of Mediums of different Densities*, a partial *Reflection takes place, proportionate in Force to the Difference of the* *length.*

"This may be illustrated, if not demonstrated, by the analogy of elastic bodies of different sizes. If a smaller elastic body strikes against a larger one, it is well known that the smaller is reflected more or less powerfully, according to the difference of their magnitude; thus, there is always a reflexion when the rays of light pass from a rarer to a denser stratum of ether, and frequently an echo when a sound strikes against a cloud. A greater body striking a smaller one propels it, without losing all its motion; thus, the particles of a denser stratum of ether do not impart the whole of their motion to a rarer, but, in their effort to proceed, they are recalled by the attraction of the refracting substance with equal force; and thus a reflexion is always secondarily produced, when the rays of light pass from a denser to a rarer stratum. But it is not absolutely necessary to suppose an attraction in the latter case, since the effort to proceed would be propagated backwards without

Interference spectrum.

Wave-lengths for different homogeneous rays.

Complementary grating.

Shadow of circular disk.

<sup>1</sup> *Spectra Solvuta*, 1863.

<sup>2</sup> A tenth are nearly 25 millimetres in an inch, these numbers each multiplied by 4 give the wave-length approximately in thousand-millionths of an inch.

<sup>3</sup> Gilbert's *Annalen*, lvi., 1817.

It, and the undulation would be reversed, a rarefaction returning in place of a condensation; and this will perhaps be found most consistent with the phenomena."

This idea, of a rarefaction returning by reflexion when a condensation is incident, is equivalent to a loss or gain of half a wave-length when light in a denser body is reflected at the surface of a rarer body. Whether, then, the plate be denser or rarer than the medium surrounding it, one or other of the two interfering rays loses half an undulation more than the other in the mere act of reflexion. This completely removes the difficulty. But Young went farther, and pointed out that if a thin plate be interposed between two media, one rarer, the other denser than the plate, this half wave-length effect should disappear. He verified this conjecture by direct experiment, founded on a modification of a process due to Newton.

**Newton's rings.** Newton had, long before, devised and carefully employed an excessively ingenious (because extremely simple and effective) method of studying the colours of thin plates. It consisted merely in laying a lens of long focus on a flat plate of glass. The film of air or other fluid between the spherical surface and its tangent plane has a thickness which is directly proportional to the square of the distance from the point of contact. When such an arrangement is looked at in homogeneous light, the lens having been pressed into contact with the flat plate, there is seen a central black spot, surrounded by successive bright and dark rings, whose number appears to be practically unlimited. The radii of the successive bright rings were found by Newton to be as the square roots of the odd numbers 1, 3, 5, &c. Hence the thicknesses of the film of air are directly as these numbers. When rays of higher refrangibility are used the rings diminish in diameter. Hence when white light is employed we have a superposition of coloured rings of all sizes, but it is no longer possible to trace more than four or five alternations of *bright* and *dark* rings- the colours being then more and more compound. This series of coloured rings is named after Newton, and the successive colours, gradually more and more composite, form Newton's *scale of colours*. Thus we read, in books more than thirty years old, of a red or blue of the *third order*, meaning those colours as seen in the third bright ring round the central dark spot.

**Colours of grooved surfaces.** Many of the most vivid colours of natural and artificial bodies are due to one or other of the forms of interference we have roughly explained. Thus Barton's *buttons* (once employed for ornament as they produce an effect very similar to that of diamonds) were simply polished metal plates stamped by a die of hardened steel, on whose surface a pattern had been engraved consisting of small areas ruled in different directions with close equidistant parallel grooves. That the colours of a pearl and of mother-of-pearl are due to a similar surface corrugation was proved by Brewster, who took impressions from such substances in black wax, and found that it was thus rendered capable of giving the same play of colours. The scales from the wings of butterflies owe their bright colours to a delicate ribbed structure. On the other hand, the thin transparent wings of the house-fly, earwig, &c., owe their colours to their thinness. The same is true of the temper colour of steel, Nobili's rings, &c. Very beautiful examples of thin plates scaled off from decayed glass (found in Roman excavations) have been figured, with their play of colours, by Brewster.<sup>1</sup>

**Refractive index in terms of wave-length.** Here we can only say a word or two about the probable relation between the wave-length of homogeneous light and its refractive index for any isotropic medium. The existence of dispersion was attributed by Cauchy to the fact that even the most homogeneous media, such as water,

have grained or heterogeneous structure of dimensions not incomparably smaller than the average length of a wave of light. This grained structure has been recently proved to exist, by several perfectly independent processes arising from totally unconnected branches of physics; and its dimensions have been assigned, at least in a roughly approximate manner. See ATOM, and CONSTITUTION OF BODIES.

It appears from the theory of disturbances in such a medium that the velocity of a ray depends upon its wave-length in a manner which is expressed by a series of even inverse powers of that wave-length. Hence we have a relation such as

$$\mu = a + \frac{\beta}{\lambda^2} + \frac{\gamma}{\lambda^4} + \dots$$

in which, from our present ignorance of the precise connexion between matter and ether, we must be content to find the multipliers of the various terms by direct measurement. If we neglect all but the first two terms, we may determine  $a$  and  $\beta$  from the known wave-lengths of two of Fraunhofer's lines, and their refractive indices for a particular medium. We can then test the accuracy of the formula by its agreement with the corresponding numbers in the same medium for others of the fixed lines. Thus, taking the data for water given above, we have, from the numbers for the two hydrogen lines C and F, the values

$$a = 1.3243, \\ \beta = 0.00000000319.$$

Calculating from these, and the wave-length of H, we have for its refractive index 1.3447, instead of 1.3442 as determined by Fraunhofer. So far as we may trust this theory, which certainly accords fairly with the experimental data for substances of moderate dispersivity, though by no means well with those for substances of high dispersive power such as oil of cassia, the value of the quantity  $a$  is the refractive index for the *inferior limit* of the spectrum; i.e. it is that of the inferior limit of the spectrum.

**DOUBLE REFRACTION.**—We now come to phenomena which cannot be even roughly explained by processes based on the vague analogies of sound and water waves which have hitherto sufficed for our elementary treatment of the subject.

These phenomena were first observed in Iceland spar. They were described in a general way by Bartholinus, who showed that one of the two rays into which a single incident ray is divided by this substance follows the ordinary law of refraction. Huygens, who studied the subject only eight years later, verified the greater part of the results of Bartholinus, and added many new ones. From his point of view it was of course obvious that the ordinary ray is propagated by spherical waves, i.e., its velocity is the same in all directions inside the crystal. To explain the extraordinary ray, he assumed that it was propagated in waves of the form of an ellipsoid of revolution, the simplest assumption he could make. To test its accuracy he first noticed that a rhombohedral crystal of Iceland spar behaves in precisely the same way whichever pair of parallel faces he it passes through. Hence he acutely concluded that the axes of the ellipsoids of revolution (if such were the form of the waves for the extraordinary ray) must be symmetrically situated with regard to each of these planes. The only such lines in a rhombohedron are parallel to that which joins those corners which are formed by the meeting of three equal plane angles. In the case of Iceland spar these equal angles are obtuse. Huygens then verified, by experiments well contrived, though carried out by a very rough mode of measurement, the general agreement of his hypothesis with the fact; and he further tested it by comparing its indications as to the position of the two images for any position of the crystal

**Wave-surface of extraordinary ray.**

<sup>1</sup> *Trans. Roy. Soc. Edin.* 1861.

with the results of direct observation. There can be no question that the whole investigation was, for the age in which it was made, of an exceedingly high order. But it must not be left unsaid that far more accurate measurements than those of Huygens were necessary before it could be asserted that the form of the extraordinary wave is an ellipsoid of revolution, and not merely a surface closely resembling such an ellipsoid. These improved measurements were made 1802 by Wollaston, and they have recently been repeated with far more perfect optical means by Stokes, Mascart, and Glazebrook. The result has been the complete verification of Huygens's conjecture. The generating ellipse of the extraordinary waves is found to have its minor axis, which is that of revolution, equal to the diameter of the corresponding sphere for the ordinary ray. Its major axis is to the minor nearly in the ratio 1.654:1.183.

We are now in a position to trace the paths of the two rays into which a ray falling in any direction on a surface of the crystal is divided by refraction.

Refraction by Iceland spar.

Let fig. 31 represent a plane wave front AB (in air) falling on the surface AC of a piece of Iceland spar cut in any way. The figure is a section perpendicular to the surface, and parallel to the incident ray. The wave front AB cuts the surface of the spar in a line (not shown) at right angles to the plane of the paper. Draw from A the axis Aa (not necessarily in the plane of the paper) and the sphere and ellipsoid of revolution which have Aa for a common axis. Then, if C be taken such that BC is to Aa as the velocity of light in air is to that of the ordinary ray in

the crystal, the wave front of the ordinary ray is found by drawing a tangent plane to the sphere, passing through C and perpendicular to the plane of the paper. This touches the sphere in a point *a* (in the plane of the paper) and AaO is the ordinary ray.<sup>1</sup> To find the direction of the extraordinary ray, a plane perpendicular to the paper, and passing through C, must be drawn so as to touch the ellipsoid. Let *e* be the point of contact, which will in general not be in the plane of the paper unless Aa is in or perpendicular to that plane; then AaE is the extraordinary ray.

Thus, in general, the extraordinary ray is not in the plane of incidence. Also the ratio of the sines of the angles of incidence and refraction is generally different for different directions of incidence, in the case of the extraordinary ray.

In an elementary article we cannot attempt more fully to study these phenomena; so we merely state that all the observed appearances, so far as the directions of the

refracted rays are concerned, are explained by supposing the wave-surface in the crystal to be made up of the sphere and the ellipsoid of revolution above described. Thus, when both eyes are used, the two images of a plane object seen through a crystal of Iceland spar appear in general to be situated at different distances above the plane. One of them maintains its apparent position as the crystal is made to rotate about a perpendicular to the two faces employed; the other's position varies as the crystal is turned.

But we have now to inquire why the incident ray is divided into two, and why one of them follows the ordinary law of refraction. Here another experimental result of Huygens comes to our assistance. We paraphrase the author's description:—

"I will, before concluding, mention another remarkable phenomenon which I discovered after the above was written. For, though I have not yet been able to find the cause of it, I do not wish on that account to refrain from pointing it out, in order that others may have an opportunity of seeking to explain it. It appears that it will be necessary to make hypotheses additional to those already given, though these will lose none of their probability, confirmed as they have been by so many tests. The phenomenon is that, taking two fragments of the crystal (Iceland spar) and laying them on one another, or even holding them apart, if all the faces of the one be parallel to those of the other, a ray of light divided into two by the first fragment will not be further subdivided by the second. The ordinary ray from the first will be refracted ordinarily by the second, the extraordinary ray extraordinarily. And the same thing happens not only in this arrangement but in all others in which the principal sections<sup>2</sup> of the two fragments are in the same plane, whether the surfaces turned towards one another be parallel or not. It is, in fact, marvellous that these rays, falling on the second fragment, do not divide like the ray incident on the first. One would say that the ordinary ray from the first fragment had lost what is necessary for the production of extraordinary refraction, and the extraordinary ray that which is necessary for ordinary refraction; but there is something else which upsets this view. For when one places the fragments so that their principal sections are at right angles, whether the opposed surfaces be parallel or not, the ordinary ray from the first suffers only extraordinary refraction by the second, and *vice versa*.

"But in all the infinite number of positions other than those named, both rays from the first fragment are divided into two by the second. Thus the single incident ray is divided into four, sometimes equally, sometimes unequally bright, according to the varying relative position of the crystals. But all together do not seem to have more light than has the single incident ray.

"When we consider that, the two rays given by the first crystal remaining the same, it depends upon the position of the second crystal whether they shall be divided into two or not, while the incident ray is always divided, it appears that we must conclude that the rays of light which have traversed the first crystal have acquired a form or disposition which in some positions enables them to excite the two kinds of matter which give rise to the two kinds of refraction, in other positions to excite only one of them. But I have not yet been able to find any satisfactory explanation of this."

So far Huygens. His statements are perfectly in accordance with fact; and they were reproduced by Newton<sup>3</sup> in very nearly the same form. Newton adds:—"The unusual refraction is, therefore, performed by an original property of the rays. And it remains to be enquired, whether the rays have not more original properties than are yet discovered. Have not the rays of light several sides, endued with several original properties?"

It is very curious to notice how near each of these great men came to the true explanation, and yet how long time elapsed before that explanation was found. The date of Huygens's work is 1690, that of Newton's 1704. It was not till 1810 that farther information on the subject was obtained. Then one brilliant observation opened the way for a host of discoveries in a new and immense field of optics.

<sup>2</sup> Defined as passing through the shorter diagonal of one of the rhombic faces of the crystal, and through the edge formed by the two adjacent faces.

Images seen through Iceland spar.

Polarization by reflexion.

In the last-mentioned year Malus, while engaged on the theory of double refraction, casually examined through a doubly refracting prism of quartz the sunlight reflected from the windows of the Luxembourg palace. He was surprised to find that the two rays alternately disappeared as the prism was rotated through successive right angles, —in other words, that the reflected light had acquired properties exactly corresponding to those of the rays transmitted through Iceland spar. Even Malus was so imbued with the corpuscular theory of light that he named this phenomenon *polarization*, holding it as inexplicable on the wave theory, and as requiring a species of polarity (akin to the magnetic) in the light-corpuscles — a close reproduction of one of Newton's guesses.

Transverse vibrations.

But after a short time Hooke's old guess was independently reproduced, and in the hands of Young and others, but most especially of Fresnel, the consequences of the assumption, that the vibrations of the luminiferous medium take place *perpendicularly* to the direction of the ray, were the almost complete explanation of the cause of double refraction, and the discovery (often the prediction) of a long series of the most gorgeous phenomena known to science.

The real difficulty in the way of this conception probably lay in the fact that most of the familiar forms of wave-motion — such as sound-waves in air or in water, and ordinary water waves — are not of this character. In sound-waves the vibrations are wholly in the direction of the ray, while in surface waves in water they are partly parallel to and partly perpendicular to the direction in which the wave is travelling. That a body may transmit waves in which the vibration is perpendicular to the direction of a ray, it must have the properties of an elastic *solid* rather than of a fluid of any kind. And our experience of the almost entire absence of resistance to the planetary motion seems, at first sight at least, altogether incompatible with the idea that the planets move in a jelly-like solid, filling all space through which light can be propagated.

Analogies.

Without going into difficult dynamical details, we may obtain a notion of the nature of the motion now to be considered, by observing the propagation of a wave when a long stretched wire or string is struck or plucked near one end. Here the line of motion of each part of the wire is almost exactly perpendicular to the direction of the wire, i.e. to the line along which the wave travels. (When the string is extensible there may be another wave, due to extension; but this, which is analogous to sound, has its vibrations *along* the string, and it usually travels at a very different rate from the other, so that the two are not in any way associated).

Interference of polarized rays.

Now it is clear that waves of this wholly transverse character can have, in Newton's language, *sides*. And it is also clear that they cannot interfere so as mutually to destroy one another unless their corresponding sides are parallel to one another; nor can they interfere *at all* if their sides are perpendicular to one another. Hence a very severe test of the theory will be furnished by examining various cases of interference of polarized light, which ought to present in general marked differences from those of ordinary light. It was by experiments of this kind that Fresnel and Arago first firmly established the bases of the theory of polarization. The important fact discovered by Malus was soon generalized into the following statement:—

Polarizing angle.

Light reflected from the surface of substances so different as water, glass, polished wood, &c., at a certain definite angle, which depends on the nature of the substance, is found to possess all the properties of one of the rays transmitted through Iceland spar. If the plane of re-

flexion is parallel to the axis of the spar, the properties of the reflected light are those of the *ordinary* ray; if perpendicular to it, those of the *extraordinary* ray.

It was reserved for Brewster to discover, as the result of an extraordinary series of experimental measurements, the very simple law which follows:—

*The tangent of the polarizing angle is equal to the Brewster's law.*

This may be put in another form, in which its connexion with theory is a little more evident:—

*When the reflected ray is completely polarized, it is perpendicular to the refracted ray.*

Bearing in mind Huygen's observations on light which has passed through two crystals of Iceland spar, we can now see that a ray of light polarized by reflexion is in general divided into two by a crystal of Iceland spar. But there is only one ray when the principal plane of the crystal is parallel to the plane of reflexion, and none when the planes are perpendicular to one another.

We may now much simplify matters by passing the Polarizer Iceland spar, and using two reflecting plates of glass, so placed that a ray meets each of them in succession at the polarizing angle. It is then found that, when the planes of reflexion are parallel the ray is reflected (almost without loss) from the second plate, but when they are perpendicular to one another the ray is extinguished. In intermediate position the intensity was found by Arago to be as the square of the cosine of the inclination of these planes.

This very simple experiment, which any one may easily make for himself, by putting two pieces of glass at the proper angle in the ends of two wooden tubes which fit into one another, enables us to form a general notion of the modification which is called polarization. The "sides" of the reflected ray are obviously in, and perpendicular to, the plane of incidence; for a ray can be reflected over and over again in successive planes, and none can be reflected at once if one plane is perpendicular to the others.

Here, however, two new difficulties come in at once:—Diff.

(1) Are the vibrations of the reflected ray in, or perpendicular to, the plane of reflexion? (2) As ordinary sun or lamp light, reflected at the proper angle from a polarizing surface, shows no variation of intensity when the azimuth of the plane of reflexion is changed, what can be then the direction of its vibration? These questions have not yet been answered in a thoroughly satisfactory manner.

Many important phenomena are explained in terms quite independent of the proper answer to (1), and, in others which do depend on the answer, the theoretical differences between the results of the two hypotheses are so small as to have hitherto remained undetected. In an important test, suggested by Stokes, the experimental results have been at variance in a way which could not be explained. It is quite possible that, as is required by Clerk Maxwell's *electromagnetic theory* of light (see *Electricity*), there may be simultaneous displacements, but of different characters, in each of these planes, and then the question would be reduced to: Which of these displacements is the luminous one? But on this theory, *both* are probably essential to vision.

As to the second question, it may be said, *first*, that, Nature so far as the test of double refraction can inform us, is of common light. polarized ray whose plane of polarization is made to rotate rapidly produces precisely the same effects as a ray of ordinary light; and, *secondly*, that, so great is the number of vibrations even of red light in one second, it would be impossible to make the plane of polarization rotate fast enough to affect the circumstances of any of the phenomena of interference, even when they take place between two portions of the same ray, one of which is retarded

Plane of vibration and plane of polarization.

thousands of wave-lengths more than the other. But, *thirdly*, the fact that, when homogeneous light is used, Newton's rings have been counted up to the 7000th shows that, whatever be the actual nature of the vibrations of unpolarized light, they must for at least 7000 waves in succession be almost precisely similar to one another. Then, for other 7000 waves or so, we may have a totally different type of vibration. But, *fourthly*, in the course of  $\frac{1}{10}$ th of a second, at the very utmost, the vibrations must have been almost uniformly distributed over all directions perpendicular to the ray. Again, however, *fifthly*, another quite different view may be suggested. All common light has its origin from a practically infinite number of sources, consisting of the vibrating particles of the luminous body. The contributions from each of these sources (so far as one definite wave-length is concerned) may be and probably are at any one point as different in direction of vibration as they certainly must be in phase.<sup>1</sup> From this point of view, which we cannot develop here, the uniformity of optical phenomena becomes quite analogous to the statistical species of uniformity which is now found to account for the behaviour of the practically infinite group of particles forming a cubic inch of gas. The reader need only think of the fact that, so numerous are those particles, it is practically (though not theoretically) impossible that even a cubic millimetre of air should, even for  $\frac{1}{1000000}$ th of a second, contain oxygen particles alone.

**Reflexion not at the polarizing angle.** When light is reflected at an incidence either less or greater than the polarizing angle, it behaves as if part of it only were polarized and the rest ordinary light; and it is said to be *partially polarized*. Tested by a crystal of Iceland spar, it gives two images in all positions of the crystal; but their brightness is unequal except in the special positions where they would be of equal brightness were the ray wholly polarized.

**Polarization by ordinary refraction.** From the fourth of the remarks made above regarding common light, and the facts of double refraction, it follows at once that, when light is to any extent polarized by reflexion, there must be an exactly equal amount of polarized light in the refracted ray, and its plane of polarization must be perpendicular to that of refraction. This was established by experiment soon after Malus's discovery. But as the reflected ray from glass, water, &c., is in general much weaker than the refracted ray, the percentage of polarized light is generally much greater in the former. It was found, however, by experiment that refraction at a second glass plate parallel to the first increases the proportion of polarized to common light in the transmitted ray, and thus that light may be almost completely polarized by transmission, at the proper angle, through a number of parallel plates. The experimental data of this subject were very carefully obtained by Brewster. He has found, for instance, how the angle of incidence for the most complete polarization varies with the number of plates. The plane of polarization of such a bundle is *perpendicular* to the plane of refraction.

This, however useful on many occasions, is at best a rough arrangement for producing polarized light. By far the most perfect polarizer for a broad beam of light is a crystal of Iceland spar, sufficiently thick to allow of the complete separation of the two rays. But such specimens are rare and costly, so that the polarizer in practical use is now what is called *Nicol's prism*, invented in 1828 (*Jameson's Journal*, p. 83). By cutting a rhomb of Iceland spar in two, and cementing the pieces together with Canada balsam (after carefully polishing the cut faces),

Nicol produced an arrangement in which one only of the two rays is transmitted, the other being totally reflected at the surface of the balsam. The reason is simply that the refractive index of Canada balsam is intermediate to those of the ordinary and extraordinary rays in the spar. The ordinary ray, falling very obliquely on a medium of a smaller refractive index, is *totally* reflected; the extraordinary ray, falling on a medium of greater, but very little greater, refractive power, is almost wholly transmitted. The only defect of the Nicol's prism is that, to secure the total reflexion, its length must be considerably greater than its breadth; and thus it necessarily limits the divergence of the beam it allows to pass.

Certain doubly refracting crystals exert considerable **Polarization by absorption.** absorption on one of the two rays they produce, and can therefore, when in plates of sufficient thickness, be employed as polarizers. This is the case with some specimens of tourmaline when cut into plates parallel to the axis of the crystal. It is also found in the flat crystals of several artificial salts, such as, for instance, iodo-sulphate of quinine.

Let us now suppose that by one or other of these pieces **Two of apparatus, say a Nicol's prism, light has been polarized. Nicol's.** If we examine this ray by means of a second Nicol, placed in a similar position to the first, it passes practically unaltered. As the second Nicol is made to rotate, more and more of the light is stopped, till the rotation amounts to a right angle. Two well-constructed Nicols, placed in this position, are practically opaque to the strongest sunlight. During the next quadrant of rotation the transmitted ray gradually increases in brightness, until at 180° of rotation it passes practically unaltered. Precisely the same phenomena occur in the same order during the next half of a complete rotation. The reader will observe that this is merely Huygens's original statement, limited to one of the four rays which are produced by passing common light successively through two crystals of Iceland spar.

Whatever be the true mechanism of polarized light, **Symmetry of polarized ray.** there can be no doubt that its vibrations are *symmetrical* with respect to the ray, and also with respect to the plane of polarization. Hence we may, for many important purposes, symbolize them by simple harmonic vibrations taking place either in or perpendicular to the plane of polarization. But, if they be supposed to take place simultaneously in these two planes, their quality or nature must be essentially different in the two, else the symmetry above referred to would be violated. Hence it will be sufficient for the present to assume that they take place perpendicular to the plane of polarization. The nature of the resulting effects, so far as the eye is concerned, will not be different for the different hypotheses. Also, as no instance has yet been observed, even with the most intense beams of light, in which the joint effects observed are not those due to simple superposition, we may assume that the elastic force of the luminiferous medium, called into play by a displacement, is directly proportional to the displacement, and therefore that the vibrations for each wave-length follow the *simple harmonic law*, that of the cycloidal pendulum.

The subject of the composition of simple harmonic motions of equal period falls to be discussed as an important branch of *kinematics* (see *MECHANICS*). We will therefore here assume the following results,—referring to the above-quoted article for their proof:—

1. Two simple harmonic motions of the same period, in lines perpendicular to one another, give, in general, elliptic motion, which may be in the positive or negative direction of rotation. **Proper ties of simple harmonic motion.**
2. The ellipse becomes a straight line, and the resultant motion therefore simple harmonic, when the phases of the

<sup>1</sup> A curious exception occurs in the case of light radiated from a body which polarizes by absorption. See RADIATION.

components are the same, or differ by an integral multiple of  $\pi$ .

3. It becomes a circle when the amplitudes of the components are equal, and their phases differ by an odd multiple of  $\frac{1}{2}\pi$ . The motion takes place in one direction (say right-handedly) in the circle when this multiplier is 1, 5, 9, 13, &c., and in the opposite (left-handed) when it is 3, 7, 11, 15, &c. . .

Effect of a plate of doubly refracting material.

Homogeneous light.

Now, suppose a plane polarized ray to fall on a plate of a doubly-refracting crystal (a thin plate of mica or selenite, for instance). Within the plate it will in general be divided into two, which are polarized in planes at right angles to one another. The directions of vibration in these rays are determined by the physical properties of the material. Let them be represented by the lines  $Ox$ ,  $Oy$  in fig. 35. Then, if  $OA$  represents the semiamplitude of vibration in the incident ray, it may be looked on by (2) above as the resultant of two simple harmonic motions of the same period, whose semiamplitudes are  $OM$  and  $ON$ , and which are in the same phase. Each of these will pass through the plate of crystal unchanged. But one will, in general, travel faster than the other; for the essential cause of double refraction is the difference of velocities of the two rays. The portions of the two rays which simultaneously escape from the crystal, and which travel together outside it, will therefore differ in phase. Hence, to find the nature of the transmitted light, we must recombine the vibrations in  $OM$ ,  $ON$ , taking account of this difference of phase. By (1) above the result will be in general elliptic motion. The ellipse will necessarily be one of the infinite number which can be inscribed in the rectangle  $AA'BB'$ , whose construction is obvious. We have then, in general, what is called *elliptically polarized light*. This degenerates (by (2) above) into plane polarized light, whose vibrations are along  $OA$  or  $OA'$  according as the difference of phase is  $0, 2\pi, 4\pi$ , &c., or  $\pi, 3\pi, 5\pi$ , &c. And it will become *circularly polarized light* if  $OM = ON$  (i.e., if  $AOx = \frac{1}{2}\pi$ ) and the difference of phase be an odd multiple of  $\frac{1}{2}\pi$ . By (3) above this will be right or left handed, according to the value of the odd multiplier.

Elliptically and circularly polarized light.

This conclusion from the assumption above made is fully borne out by experiment. When a plate of mica, of such a thickness as to retard one of the two rays a quarter of a wave-length more than the other, is interposed between two Nicols, we observe the following phenomena:—

If the Nicols were originally placed so as to extinguish the light, the introduction of the mica plate in general partially restores it. Now, let the mica plate be made to rotate in its own plane. The light vanishes for successive positions, differing by a quadrant of rotation, i.e. whenever the directions of vibration in the crystal coincide with the principal planes of the Nicols. In each of these positions the light from the first Nicol passes unchanged through the mica, and is therefore entirely stopped by the second Nicol. Half-way between these positions the light transmitted through the system is at its brightest; and in these cases it is not altered in brightness by rotating the second Nicol. It is then circularly polarized, and in whatever direction the second Nicol is placed the component of the circular motion which is ready to pass through it is of the same amplitude. Here, then, is a case in which a Nicol (the second) cannot enable us to distinguish between common light and light very seriously modified.

Fig. 35.

In what precedes, we have assumed that *homogeneous* white light was used. In general, a doubly-refracting plate light produces a difference of phase in its two rays which will depend on their wave-length; and thus when white light is used we have a display of colour, sometimes extremely gorgeous, and we may distinguish light thus circularly polarized from common light by slight changes of colour and intensity as the second Nicol is turned.

Hitherto we have spoken of the polarizing angle for light reflected in air from bodies such as glass, water, &c., which have a higher refractive index than air, and we have seen that an equal amount of light is polarized in the refracted beam. But what if there be no refracted beam? This is the case of total reflexion inside the denser body. Fresnel discovered that in this case the two kinds of polarized light (in planes at right angles to one another) co-exist in the totally reflected ray, but that they differ in phase, and therefore in general recombine into elliptically polarized light. Guided by peculiar theoretical considerations, he was led to construct a piece of glass (*Fresnel's rhomb*), inside which light is twice totally reflected at a certain angle with the result that, if it be originally polarized in a plane inclined at  $45^\circ$  to the plane of reflexion, the emergent light is circularly polarized.

Reflexion from the surface of metals, and of very highly refractive substances such as diamond, generally gives all incidences elliptically polarized light. Attempts have been made to determine from such effects the refractive indices of metals and other opaque substances. These are all based upon theory, and cannot as yet command much confidence. With certain doubly-refracting substances the light reflected at a definite angle is differently polarized, and sometimes even differently coloured, for different azimuths of the plane of incidence.

When a thin plate of doubly-refracting crystal, which gives a bright colour when placed between two Nicols, is slightly inclined to the ray, the colour changes as the difference of phase of the two refracted rays is increased. If, now, we take a plate of Iceland spar cut perpendicularly to the axis, no colour will be produced by parallel rays passing through it perpendicularly, because both rays have a common velocity parallel to the axis; but, if divergent light be used, there is a gorgeous display of circular coloured rings surrounding the axis, which depends upon the increasing retardation of the ordinary ray behind the extraordinary as their inclination to the axis increases. When the principal planes of the Nicols are at right angles, this system of rings is intersected by two black diameters, in these planes respectively. When the second Nicol is turned through a right angle, we have exactly the complement of the former appearance, i.e., a figure such that, if superposed on the former, it would give an uniform field of white light.

It is to be noticed that none of these phenomena can be observed without the use of the second Nicol. This arises from the fact that, where the vibrations in any direction interfere so as to destroy one another, those in the direction perpendicular to the former interfere so as to strengthen one another. The second Nicol enables us to select one of these portions, and examine it independently of the other.

The only double refraction we have considered particularly is that of Iceland spar, where everything is symmetrical about the axis of the crystal. Such crystals, and they include as a rule all those of the second and third systems in *CRYSTALLOGRAPHY* (*q.v.*), are called *uniaxial*. Crystals of the first system are not doubly refractive. But it was one of the most valuable of Brewster's discoveries that the great majority of non-isotropic substances are doubly refracting, and in general are *biaxial*, i.e., have two

Effect of total reflexion.

Metallically reflexion.

Rings and cross in plate of uniaxial crystal.

Fresnel's wave.

equally important axes inclined to each other at angles of all values from 0 to 90°. The form of the *wave-surface* in such bodies was, at least very approximately, assigned by Fresnel. This forms one of the most brilliant of his many grand discoveries; and it led to Hamilton's prediction of the existence of the two species of *conical refraction*, which was experimentally verified by Lloyd.

Conical refraction.

Double refraction due to strain.

Fresnel also made the striking discovery that glass and other simply refracting bodies are rendered doubly refracting when in a state of strain. To this Brewster added the observation that the requisite strain might be produced by unequal heating instead of by mechanical stress, and also that unannealed glass is usually doubly refractive. Clerk Maxwell in 1873 (*Proc. Roy. Soc.*) showed that shearing stress in viscous liquids, such as Canada balsam, renders them temporarily doubly refractive. This subject has been elaborately investigated by Kundt (*Phys. Ann.*, 1879).

The details of these subjects, with those of the polarization of light reflected from small particles, the *rotatory polarization* produced by quartz, sugar, transparent bodies under the influence of magnetism, &c., must be deferred to OPTICS (PHYSICAL).

There is, however, one elementary point which must not be omitted here, as it is intimately connected with the wave-theory, that is, the alteration which light undergoes in consequence of the relative motion of the source and spectator in the line of vision.

Doppler's principle

When a steamer is moving in a direction perpendicular to the crests of the waves, she will encounter more of them in a given time if her course is towards them than if she were at rest, while, if she be moving in the same direction as the waves, fewer of them will overtake her in a given time than if she were at rest. The same thing is true of sound-waves. When an express train passes a level crossing at full speed, the pitch of the steam whistle is higher during

the approach to and lower during the recess from the listener at the gate than it would be if the engine were at rest. The successive sound pulses are emitted at the same intervals as before, but from points successively nearer to or farther from the listener. Hence more or fewer reach his ear in a given time. The principle is precisely the same as that of Römer's observation of the frequency of eclipse of Jupiter's satellites, which we have already given: the number of light-waves which reach the eye per second is increased if the source is approaching, and diminished if it be receding. We are now dealing with a phenomenon which occurs some 600,000,000,000,000 times per second instead of once every forty-two hours. Now, increased wave-frequency, with unaltered velocity of light, certainly implies shorter wave-length and most probably greater refrangibility, and *vice versa*. There is, undoubtedly, a weak link in this reasoning, due to our ignorance of the true nature of the luminiferous medium and of the species of vibration on which light depends. If we knew something definite about the nature of the ether, and the mechanism of its vibrations, this weakness would be at least in part got rid of. Observation has not yet settled the question of the relative motion of bodies, the ether they contain, and the ether in free space.

This principle has been applied with success by Huggins and others to find the rate at which we are approaching to or receding from different fixed stars, and the rate of motion in solar cyclones; and it may even be applied, as was ingeniously suggested by Fox Talbot (*B. A. Report*, 1871), to determine (from the relative velocities of the components of a double star in the line of sight, measured by its aid) the distance of the star itself from our system.

The reader is advised to consult, in connexion with the whole of the second part of this article, the previous article *ETHER*. (V. G. T.)

LIGHTFOOT, JOHN (1602-1675), an eminent rabbinical scholar, was the son of Thomas Lightfoot, vicar of Uttoxeter, Staffordshire, and was born at Stoke-upon-Trent in that county, on March 29, 1602. His school education was received at Morten Green near Congleton, Cheshire, and in June 1617 he entered Christ's College, Cambridge, where he made great progress in Latin and Greek, and was reckoned the best orator among the undergraduates. After taking his bachelor's degree, he became for some time assistant master at Repton in Derbyshire; at the canonical age he received ordination, and shortly afterwards was appointed curate of Norton under Hale in Shropshire. There he attracted the notice of Sir Rowland Cotton, an amateur Hebraist of some attainments it would seem, who made him his domestic chaplain at Bellaport, and was the first to awaken his taste for rabbinical learning. Shortly after the removal of Sir Rowland with his family to London, Lightfoot followed him thither, but for some unexplained reason soon left the capital again, and, visiting his parents at Uttoxeter, took a sabbatical leave of them, having resolved "to travel beyond the seas." An unexpected and pressing invitation induced him to change his determination, and to accept a charge at Stone in Staffordshire, where he continued for about two years, and where, on May 21, 1628, he married Joyce, daughter of William Crompton of Stone Park, and widow of George Copwood of Delverne, Staffordshire. From Stone he removed to Hornsey near London, for the sake of the library of Sion College, which he often had occasion to consult; his first published work, entitled *Erublin, or Miscellaneous Christian and Judaical, penned for recreation at vacant hours*, and dedicated to Sir R. Cotton, appeared at London in 1629. During the summer

and autumn of 1630 he lived at Uttoxeter, and in September of that year he was presented by Sir R. Cotton to the rectory of Ashley in Staffordshire, where he continued to discharge his pastoral duties, and to prosecute his rabbinical studies, for the next twelve years. For the more uninterrupted pursuit of the latter he is said to have bought a small piece of land near his parsonage, and to have built upon it a small house "containing a study and withdrawing room below, and a lodging chamber above." "Here he closely followed his said studies with great delight and unwearied diligence, and did choose to lodge here very often, though it were so near to his family and parsonage house." In June 1642 he left Ashley for London; the precise occasion of the removal is not known, but probably it arose out of the necessity for personal superintendence of the publication of his next work, *A few and new Observations upon the Book of Genesis: the most of them certain; the rest, probable; all, harmless, strange, and rarely heard of before*, which appeared at London in that year with a dedication to "my dear and loving countrymen of the county of Stafford, and other my friends residing in the city of London." Soon after his arrival in the capital he became minister of St Bartholomew's church, near the Exchange; and in 1643 he was appointed to preach the sermon before the House of Commons on occasion of the public fast of March 29. It was afterwards published under the title of *Elias Redivivus*, the text being Luke i. 17; in it a parallel is drawn between the Baptist's ministry and the work of reformation which in the preacher's judgment was incumbent on the parliament of his own day. Lightfoot was also one of the original members of the Westminster Assembly, which held its first formal meet-

ing on Saturday, July 1, 1643; his "Journal of the Proceedings of the Assembly of Divines from January 1, 1643 to December 31, 1644," now printed in the thirteenth volume of the 8vo edition of his *Works*, is a valuable historical source for the too brief period to which it relates. He was assiduous in his attendance from the first, and, though frequently standing almost or even quite alone, especially in the Erastian controversy, exercised a material influence on the result of the discussions of the Assembly. In 1643 Lightfoot published *A Handful of Gleanings out of the Book of Exodus*, dedicated to the inhabitants of Bartholomew Exchange, and in the same year he was made master of Catherine Hall by the parliamentary visitors of Cambridge, and also, on the recommendation of the Assembly, was promoted to the rectory of Much Munden in Hertfordshire; both appointments he retained until his death. In 1644 was published in London the first instalment of the laborious but never completed work of which the full title runs *The Harmony of the Four Evangelists among themselves, and with the Old Testament, with an explanation of the chief difficulties both in Language and Sense: Part I. From the beginning of the Gospels to the Baptism of our Saviour*. The second part *From the Baptism of our Saviour to the first Passover after* followed in 1647, and the third *From the first Passover after our Saviour's Baptism to the second* in 1650. On August 26, 1645, he again had the honour of preaching before the House of Commons on the day of their monthly fast; in the discourse, which was afterwards published (*A Fast Sermon*, on Rev. xx. 1, 2), after controverting as erroneous and false the doctrine of the Millenaries, he goes on to urge upon the parliament various practical suggestions for the repression with a strong hand of current blasphemies ("I do hold it a truer point in divinity that 'errans conscientia liganda' than 'ligat'"), for a thorough revision of the authorized version of the Scriptures, for the encouragement of a learned ministry, and for a speedy settlement of the church. "I rejoice to see what you have done in platforming classes and presbyteries, and I verily and cordially believe it is according to the pattern in the mount." In the same year appeared *A Commentary upon*

*the Acts of the Apostles, chronological and critical; the Difficulties of the text explained, and the times of the Story cast into annals. From the beginning of the Book to the end of the Twelfth Chapter. With a brief survey of the contemporary Story of the Jews and Romans (down to the third year of Claudius); and in 1647 he published *The Harmony, Chronicle, and Order of the Old Testament*, which was followed in 1655 by *The Harmony, Chronicle, and Order of the New Testament*, inscribed to Cromwell, with an epistle dedicatory to his highness's honourable council. In the last named year Lightfoot, who in 1652 had commenced doctor of divinity, was chosen vice-chancellor of the university of Cambridge, but continued to reside by preference at Munden, in the rectory of which, as well as in the mastership of Catherine Hall, he was confirmed, though the influence of nonconformity after the Restoration. The remainder of his life was passionately devoted to the production of the work by which his name now chiefly lives, the *Horæ Hebraicæ et Talmudicæ*, in which the volume relating to Matthew appeared in 1658, that relating to Mark in 1665, and those relating to Luke, John, and Acts, in 1664, 1671, and 1681 respectively. Towards the close of 1663, while still professor at Cambridge to Ely (where he had been called by Sir Orlando Bridgman to a prebendal stall), he caught a severe cold, upon which, by an indiscretion in diet and work, fever supervened; falling afterwards into a lethargy which continued for about a fortnight, he died at Ely on December 6, 1675. The *Horæ Hebraicæ et Talmudicæ*, composed in *Acta Apostolorum et in Epistolis Pauli ad Romanos* were published posthumously.*

The *Horæ* of Lightfoot were first edited by 2 vols. 4to, by Bright and Styrpe in 1684; the *Horæ* of *Acta Apostolorum et in Epistolis Pauli*, appeared at Rotterdam in 1686 (vol. 1 of 4), and edited by London, at Fenchurch in 1699 (4 vols. 4to). A volume of *Reveries* was published at London in 1700. The *Horæ Hebraicæ et Talmudicæ* were also edited in Latin by Casp. Weyling, 1775 (6 vols. 4to), in English, by Goodell (Oxford, 1859). The *Horæ* and the editions of the *Bible* by Lightfoot have been reprinted by Pearson (London, 1822 &c.). It is much to be regretted that only a few of his numerous commentaries, letters, and other works have been published. The *Postscriptum* is collected in the *Postscriptum* (London, 1650).

## L I G H T H O U S E

### I. LIGHTHOUSE CONSTRUCTION.

THE primary and most important consideration relating to the design and construction of a lighthouse tower which is to be built within the tide mark is the force of the waves which may be expected to assail it, and the directions and heights at which that force will act on the building. The great waves which are found in the open ocean cannot be generated in smaller seas, and, with a due regard to economy in construction, ought not therefore to be provided against. What is wanted is to ascertain in such shorter seas the height of waves in relation to the length of "fetch" in which they are generated, and next to determine their energy when on reaching the shore or a sunken rock, and so ceasing to be waves of oscillation, they enormously increase their destructive force by becoming waves of translation. Full information as to these points and as to the marine dynamometer—an instrument used for ascertaining the force of the waves on an exposed surface—will be found in the article HARBOURS, to which the reader is referred. It is enough here to state that the law of increase in the height of waves was found by Mr T. Stevenson to be proportional to the square root of the distance from the windward shore, and that the greatest force recorded on rocks exposed to the ocean was  $3\frac{1}{2}$  tons per square foot. The relative forces of summer

and winter waves were found to be as 1 to 3, and the vertical force, after acting on a curved sea wall, was eighty-four times greater than the horizontal force at a height of 25 feet above high water.

The history of the ancient lighthouses is of so scanty a nature that we may pass at once to more modern works, commencing with Winstanley's Eddystone light.

*Winstanley's Eddystone Light*.—The Eddystone Rocks, which lie about 14 miles off Plymouth, are fully exposed to the south-western seas. The lighthouse was completed by Winstanley in four seasons. In 1698 it was finished at a height of 80 feet and the light exhibited; but in 1699, in consequence of damage by storms, the tower was increased by an outer ring of masonry 4 feet thick, and made solid from the foundation to nearly 20 feet above the rock. The height was increased to nearly 120 feet, and completed in 1700. During the well-known hurricane of 20th November 1703 the tower was destroyed. In general design as well as in details this work must be placed among the *chef-d'œuvre* of maritime engineering. For example, in plan it was polygonal instead of circular. In his blind devotion to ornamentation Winstanley violated throughout the principle of uniformity of outer profile, so as to present great obstructions to the action of the waves.

*Rudyard's Eddystone Tower*.—This work was commenced

in 1706 and completed in 1709, in the form of a frustum of a cone 92 feet high. The work consisted principally of timber, the lower part being oak carefully bolted together, and also to the rock. Above the lower structure of oak courses of stone, cramped together and fixed to the timber work and to the rock, were added in order to give weight to the structure. This lighthouse stood for forty-six years, and was destroyed by fire in 1755. In every respect the simplicity of the structure and the judicious character of the details of the design may be regarded as models of engineering. First, it rested upon a stepped level base, was circular in plan, did not wholly depend upon fixtures but upon weight, preserved a uniform external surface devoid of outside projections and ornamentation; and, above all, the engineer did not by splaying out the base needlessly throw away the small diameter which the rock afforded, but with much judgment adopted the conical form.

*Smeaton's Eddystone Tower.*—This justly celebrated work, which consisted entirely of stone, was commenced in 1756, and the masonry was finished in 1759. Smeaton was the first engineer who adopted a structure of masonry for a sea tower and dovetailed joints for the stones, which averaged a ton in weight. This work cannot be regarded as a safe model for general imitation in exposed situations, and Rudyerd's earlier tower was certainly as successful in resisting the forces to which it was exposed. Rudyerd unquestionably selected for so small a rock as the Eddystone a preferable form to that adopted by Smeaton. The sharply curved profile in Smeaton's design greatly reduced the diameter of the building at a small height above the rock, and so reduced its strength.

Fig. 1.

Smeaton's reasoning about the similarity of a tower exposed to the surf and an oak tree resisting the wind was very conclusively shown to be fallacious by the late Mr Alan Stevenson. The arching of the floors, as shown in fig. 1, was also a source of weakness which the introduction of the iron chains, shown black in the diagram, was intended to counteract. Mr Douglass in 1878 stated that "for several years the safety of the Eddystone had been a matter of anxiety and watchful care to the corporation of the Trinity House, owing to the great tremor of the building with each wave stroke." He also stated that the projecting cornice at the top had been lifted, and that the rock itself had been considerably undermined. A new tower has now (1882) been erected in place of Smeaton's by Mr Douglass.

*Bell Rock Lighthouse Tower.*—The Bell Rock, which lies 12 miles off the coast of Forfarshire, is fully exposed to the assaults of the German Ocean. The rock is of considerable extent but of a low level, the tower being covered about 16 feet at high water of spring tides. Mr R. Stevenson, of Edinburgh, when he first landed on the rock, decided to adopt a stone tower as Smeaton had done at the Eddystone, but he deviated largely from that design in the thickness of the walls, in raising the tower to 100 feet instead of 68 feet, and the level of the solid to 21 feet

Fig. 2.

above high water instead of 11 feet. Instead of employing arched floors as at the Eddystone, he adopted lintel stones for the floors which formed part of the outward walls, and were feathered and grooved as in carpentry, besides having dovetailed joggles across the joints where they formed part of the walls. It will be seen on fig. 2 that the floors instead of being sources of weakness, as in Smeaton's tower, were converted into effective bonds tying

the walls together. He also used a temporary beacon or barrack on the rock for the engineer and his workmen to live in while the tower was in progress. The bill introduced into parliament for this work in 1802 was not passed in consequence of financial difficulties. As the Bell Rock was scarcely dry at low water, while the Eddystone was scarcely covered at high water, the commissioners, in order to fortify Mr Stevenson's views, consulted Mr Telford, and before going to parliament for the second time they also, on Mr Stevenson's suggestion, obtained for the scheme the support of Mr Rennie, with whom he could afterwards advise in case of emergency during the progress of the work. The second bill was passed in 1806, and the works, which were begun in 1807, were finished in 1810, and the light was exhibited in 1811. The total weight of the tower is 2076 tons.

*Skerryvore Lighthouse.*—The Skerryvore Rocks, 12 miles off the island of Tyree in Argyllshire, which is the nearest land, are wholly open to the Atlantic. The works, designed and carried out by the late Mr Alan Stevenson, were commenced in 1838 and finished in 1843. The first temporary barrack was destroyed in 1838, and another erected on a more sheltered part of the rock. The tower, which is of a hyperbolic curve, is 138 feet high, 42 diameter at the base, and 16 at the top. Its weight is 4308 tons.

*Bishop Rock.*—The Bishop Rock, lying off the Scilly Islands, is fully exposed to the Atlantic. It was designed by the late Mr James Walker, and carried out by Mr J. N. Douglass. It is 100 feet above high water, 34 feet in diameter at the base, and 17 at top. The lowest part of the foundation of tower is covered about 19 feet at high water springs; the solid is 20 feet above high water, where the walls are 9 feet thick, and decrease to 2 feet at the top. Owing to the great tremor in this building, it has lately been found necessary to strengthen it by an internal structure of ironwork.

*Wolf Rock.*—This much exposed rock is about midway between Scilly and the Lizard Point, and is submerged to the depth of about 2 feet at high water. The first design for a lighthouse was in 1823, by Mr R. Stevenson, but it was not till 1862 that a lighthouse was commenced under the superintendence of Mr Douglass, from a design by the late Mr Walker. It is 116½ feet high; 41 feet 8 inches diameter at the base, decreasing to 17 at the top, and the walls are 7 feet 9½ inches thick, decreasing to 2 feet 3 inches. The shaft is a concave elliptic frustum, and contains 3296 tons. The lower part of the tower has projecting scarcements in order to break up the sea, but, as has been already stated in the case of the Eddystone, such projections are not in accordance with the principle of uniformity of external surface, and are, therefore, more likely to produce disturbance of the masonry than to add to its stability.

*Dhu Heartach Rock Lighthouse.*—The Dhu Heartach Rock, which is 35 feet above high water, is 14 miles from the island of Mull, which is the nearest shore. The maximum diameter of the tower, which is of parabolic outline, is 36 feet, decreasing to 16 feet; the shaft is solid for 32 feet above the rock; the masonry weighs 3115 tons, of which 1810 are contained in the solid part. The temporary barrack for the workmen was made of malleable iron bars with an iron drum on the top in which the workmen lived. This tower was designed by Messrs D. & T. Stevenson, and occupied six years in erection, the length of the working season being only about two and a half months in each year.

*Chickens Rock Lighthouse.*—The Chickens Rock lies 1 mile off the Calf of Man. The curve of the tower, which is 123 feet 4 inches high, is hyperbolic, the diameter varying from 42 feet to 16 feet. The tower is submerged 5 feet at

high-water springs. The solid is 32½ feet in height, weighing 2050 tons, the whole weight of the tower being 3557 tons. The walls decrease from 9 feet 3 inches to 2 feet 3 inches in thickness. The work was designed by Messrs D. & T. Stevenson, and was begun in 1869 and completed in 1874.

*Great Basses Lighthouse near Ceylon.*—Great Basses lighthouse lies 6 miles from the nearest land, and was designed by Mr Douglass. The tower has a cylindrical base 32 feet in diameter, above which is a tower 67 feet 5 inches high and 23 feet in diameter. The walls vary in thickness from 5 feet to 2 feet. The tower, including the base, contains about 2768 tons, and the work was finished in three years.

There are several other lighthouses in Ireland, India, and America which merit more attention than our space admits of, and we shall therefore conclude with directing the attention of the engineer to the important influence of the configuration of rocks in modifying the breaking of waves. It cannot but excite surprise that some of the structures which were erected on the Eddystone should have withstood the waves so long as they did. This fact seems to lead to the conclusion that the Eddystone Rock, at one time at least, acted to some extent as a shelter to the structures which were built on it. During a summer gale when Dhu Heartach lighthouse was being erected fourteen stones each of 2 tons weight, which had been fixed on the tower by joggles and Portland cement at the level of 37 feet above high water, were torn out and swept off into deep water, as shown on Plate VII. At the Bell Rock stones of 2 tons weight were several times swept away during the construction of the tower, while it is a remarkable fact that no stones were ever moved at the Eddystone. But what is more striking, the thin glass panes of Winstanley's first tower stood successfully through a whole winter's storms at the same level above the water as that at which the fourteen heavy blocks were swept away at Dhu Heartach, where it was found necessary from the experience acquired when constructing the lighthouse to raise the solid base of the tower to nearly the same height above the water as the glass panes in Smeaton's tower, which have hardly ever been broken during the storms of more than a hundred years.

The conclusion then which seems fairly deducible from these facts is that the level of the plane of dangerous impact of the waves above high water depends upon the relation subsisting between their height and the configuration of the rocks above and below high water, as well as perhaps on the configuration of the bottom of the sea near the lighthouse. Thus, while the rock at Dhu Heartach, from its height above high water, forms a great protection against the smaller class of waves, it operates as a dangerous conductor to the largest waves, enabling them to exert a powerful horizontal force at a much higher level than they would had the rock been lower. The lighthouse engineer must therefore beware of taking it for granted that Smeaton's Eddystone tower is a model for general imitation, and must carefully consider as best he can in what way the configuration of the rock may affect the stability of the tower which he has to design. Unfortunately in the present state of our information no specific directions can be laid down for his guidance in this matter, but the following general rules of construction may be given:—

(1) The tower should have a low centre of gravity, and sufficient mass to prevent its being upset by the waves. (2) It should be throughout circular in the horizontal plane, and either straight or continuously curved in the vertical plane, so as to present no abrupt change of outline which would check the free ascent of the rising waves, or the free descent of the falling waves, or the free vent of those passing round the tower. All external scarpments in the vertical plane, or polygonal outline in the horizontal plane,

are therefore objectionable. (3) Its height, *ceteris paribus*, should be determined by the distance at which the light requires to be seen by the sailor. The rule for determining this height will be afterwards given. (4) Where the rock is soft, or consists of ledges which are easily torn up, the tower should spring from the foundation-course at a low angle with the surface of the rock, so as to prevent its being broken up by reaction of the waves from the building; or, in other words, the tower must have a curved profile. But special care should be taken to sink the foundation-course below the surface of the rock, as the superincumbent weight decreases with the sine of the angle of inclination of the wall. If the rock overhangs, owing to the wearing action of the waves, the tower should, if possible, be built at a distance from the place where this dangerous action is in progress. (5) Where the rock is hard and of ample area, the tower may be of such a curved form as will best suit the economic arrangement of the materials, so as to avoid an unnecessary thickness of the upper wall. (6) When the rock is hard, but of small dimensions, the diameter above the base should not be suddenly reduced by adopting a curved profile, but a conical outline should be adopted, and if the rock be hard, but of yet smaller dimensions, a cylindrical form or conical one should be adopted so as to thicken the walls, and to increase the weight and therefore increase the friction, when a conical profile is proportional to the weight of the blocks of masonry. In cases where the rock is small the thickness of the walls should decrease by steps or scarpments *alternately*, but never *continuously*. (7) The level of the top of the solid part of the tower, and the thickness of the walls above it, should, in different towers having the same exposure, be determined in each case by the level and configuration of the rock and of the bottom of the sea. (8) The best position for the tower is not necessarily the highest part of the rock. It should, in each case, be selected so as to secure the greatest protection in the direction of the maximum fetch and deep of water in the reef. (9) The tower should not, if possible, be erected on any ledge on which divides the rock, or on the crevices of the rock, which projects into it, especially if it be of converging form, which would concentrate wave action. (10) No permanent fastenings of the tower to the rock is required for increasing the stability of the structure. The foundation-course (unless where a conical profile is adopted) becomes, indeed, in the end the most stable of all, because it is the greatest weight above it, to keep it in its place. (11) The stones should, however, be sufficiently connected together and fixed to the rock, in order to prevent their being washed away during the construction of the work, when they have no other adequate weight to keep them in their beds. (12) The tower should rest on a truly level base, or on level steps cut in the rock. (13) The placement of all the materials within the tower should be carefully so as not to produce a resolved force acting laterally as an outward thrust. (14) The tower should be of such height and diameter, with walls of such thickness, as to prevent the masonry being disturbed by the impact of the waves. (15) The entrance door should be placed on that side of the tower where the length of fetch is shortest, or where from the configuration of the rock and the depth of water the force of the waves is least. This was determined at the Bell Rock by the destruction of the *goss* which grew on the lower parts of the tower during the last winter, the vegetation being lost where the waves were heaviest. (16) The materials should be of the highest specific gravity that can be readily obtained, and, in some special cases, lead, or dove-tailed blocks of cast iron set in cement, might perhaps be employed.

Plate VII. shows sections on the same scale of a number of the more remarkable lighthouse towers.

Fig. 3 shows an iron pile light erected at Haneda, in the Bay of Yedo, Japan.

*Modes of Uniting the Stones and Courses of Masonry.*—Fig. 4 (p. 618) shows the mode of combining the stones during construction at different lighthouses in the United Kingdom and in America.

FIG. 3

## II. LIGHTHOUSE ILLUMINATION.

What is required of every lighthouse apparatus is either the equal distribution of the rays constantly or periodically over the whole horizon, or else their unequal distribution over certain azimuths only.

The first of these two cases, viz., the equal distribution of the light, will be best understood by explaining the different manner in which the rays are operated on by the apparatus for a fixed light and by that for a revolving light. The characteristic of a *fixed* light, which is that of being seen constantly and always of the same power round the whole horizon, might no doubt be perfectly produced by a naked flame without any apparatus, but then all the rays which did not fall on the navigable track of shipping would be lost to the sailor. In order then to intercept and utilize those rays which, instead of falling on this navigable track, would either go upwards to the sky or downwards on the shore close to the lighthouse tower, and on that part of the sea which is very near the shore, we must have recourse to optical agents both for bending down the rays which naturally point too high, and for bending up those which point too low. It thus appears that the apparatus for a fixed light should bend the rays in the vertical plane only, but should not interfere with their natural horizontal divergence in azimuth.

The demands which are made on a light that has to *revolve* are not nearly so great as on one that is fixed, for the revolving light does not, like the fixed, require to illuminate the whole horizon simultaneously, but only each point of it at successive intervals of time. When the dark intervals occur, the rays from the flame which are then pointing in the direction of the dark spaces should therefore have their directions so altered laterally as to pass into the adjoining light spaces and thus to increase the power of the luminous flashes. A revolving light, though supplied by a flame of the same power as a fixed, will thus necessarily be far more intense, as it does not lose its power by diffusing the rays constantly over the whole horizon, but gathers them up into a number of separate bundles or beams of great intensity. The apparatus of a revolving light has consequently more optical work to do than that of a fixed, for the rays must be bent not only in the vertical plane but laterally in the horizontal and in all intermediate planes as well.

In the construction of lighthouse apparatus either metallic or glass agents may be employed, but it has been found by experiments that a great saving of light (about 25 per cent.) is effected when glass only is used. All kinds of apparatus may conveniently be ranged either under the *catoptric system*, where metallic reflexion only is used, the *dioptric* where the material employed is wholly glass producing refraction and total reflexion, or the *catadioptric*, in which both glass and metal are employed.

THE SYSTEM of Illuminating every Azimuth with Light of equal Power either Constantly or Periodically.

Passing over the early and rude expedients of such night marks as Catoptric as open coal fires or naked candles placed in glazed lanterns, we shall confine our attention to the gradual development of those

optical designs which are now or were lately adopted for lighthouse apparatus.

*Parabolic Reflectors.* In 1763, or at latest before 1777, parabolic reflectors were first used for lighthouse illumination by Mr

Hutchinson, dockmaster of Liverpool. In his work on *Practical Seemannship*, published in 1777, he states that the Mersey lights were fitted with reflectors (figs. 5 and 6) formed of small facets of silvered

Fig. 5.

Fig. 6.

Parabolic reflectors

Fig. 4. — Courses of various Lighthouse Towers.

glass, and made, as he says "as nearly as they can be to the parabolic curve." This is unquestionably the earliest published notice of the use of parabolic reflectors for lighthouse illumination. Up to 1782 the wicks of the lamps were of a flat form, but in that year Argand introduced wicks and burners of a hollow cylindrical form which admitted a central current of air through the burner so as to ignite the cone of gas issuing from the wick both within and without. Rumford afterwards split up the cone of gas into several concentric shells.

"It is remarkable," says Mr J. T. Chance in his excellent memoir (*Min. Ins. Civil Eng.*, vol. xxvi.), "how many inventors have contributed their respective parts to the multiple burner:— Arago, the double current; Lange, the indispensable contraction of the glass chimney; Carcel, the mechanism for an abundant supply of oil; and Count Rumford, the multiple burner, an idea made feasible by these contrivances, and finally realized by Arago and Augustin Fresnel."

*Optical Properties of the Parabolic Reflector.*—In the parabolic reflector all rays diverging strictly from the focus and falling on the paraboloid emerge in one beam of parallel rays. But as an oil light is not a mathematical point, but an object of considerable magnitude, the rays from the outside of the flame being efocal will, after reflexion, emerge as a cone whose divergence is directly proportional to the radius of the flame and inversely to the focal distance of the reflector. Its intensity must consequently vary as the squares of the distances from the lighthouse. Optical apparatus does not then prevent that divergence which is due to the flame being of sensible magnitude.

*Defects of the Paraboloid.*—It will be seen from fig. 7 that the parabolic mirror  $a$  is at best but a very imperfect instrument, for even if the radiant were strictly a mathematical point, the cone of rays (shown undotted) escaping past the lips of the mirror must be lost.

**FIG. 7.—Vertical Section.**

Fr. S. Plan.

Arrangement of reflectors.

*Mode of Employing Reflectors for Fixed and Revolving Lights.*

order to produce, on the catoptric system, a fixed light showing all round the circle, a number of reflectors ( $a, a, a$ , fig. 8) are fixed round the outside of a stationary chandelier  $n$ . As the ordinary paraboloid has about  $14^{\circ}$  of divergence, twenty-five reflectors were needed to light up continuously (though not equally) the whole horizon. If again the light was to revolve, then a revolving chandelier (fig. 9 and 10) was employed having a certain number of flat faces, on each of which was fixed a number of separate lamps and reflectors with their axes parallel to each other. When the chandelier revolved, and one of the flat sides was turned towards the sailor, he would, when at some distance from the shore, receive a flash at once from each of the mirrors which were on that face, but when the face was turned away from him a dark period would intervene until the next face came round again.

FIG. 9. Elevation.

FIG. 10. - Plan.

**Fanni  
sidéral.**

*Bordier Marcelet's Fanol Sideral*, 1819. - In order strictly to equalize a fixed light over the whole horizon, which could not possibly be done with separate reflectors, Marcelet proposed this ingenious instrument, which is generated by the revolution of the parabolic profile  $pp'$  (fig. 11) round its parameter as a vertical axis, instead of round a horizontal axis, as in all former reflectors. The vertices of the parabola are cut off, so as to permit of a common focus for the flame. The rays will therefore be reflected parallel to the horizontal axis in the vertical plane, while the natural divergence of the light in azimuth will not be interfered with. By this excellent contrivance the light was for the first time spread equally round the horizon in one continuous zone. But even though the radiants were reduced to a mathematical point, very

many of the rays (shown in hard lines in the elevation, fig. 11) are allowed to escape past the lips of the reflector, and this loss takes place all round the circle.

Fig. 11.

### DOPPEL SYMM.

Beginning in 1822, Augustin Fresnel, the eminent physicist and Dioptric mathematician, entirely revolutionized the previously existing light-system. By means of his annular lens, cylindrical refractors, and totally reflecting prisms. Before describing these and their combinations it is necessary to state that the size of the flame produces divergence with lenses as well as with reflectors. The measure of this divergence for any point of the lens is the angle whose sine is

### Colors of Names

*Practical Optical Methods*

*Annular Lens, 1748-1822.* -Bulfinch in 1748 suggested a new form **Fresnel's** of lens for burning purposes in order to save the loss of heat by annular absorption of the sun's rays in passing through a thick lens of large lens.

size whose outer profile is continuously spherical. He proposed to grind out of a solid piece of glass a lens in steps or concentric zones in order to reduce the thickness to a minimum (figs. 12 and 13). Condorcet, in his *Éloge de Buffon*, in 1773 (Paris edition, 1804, p. 35) proposed the capital improvement of building up Buffon's stepped lens in separate rings, and pointed out that the cutting of the surface into steps had the effect of correcting to a large extent the spherical aberration, or divergence from the parallel, of the rays emitted by any continuously spherical lens. Sir D. Brewster, in 1811, also described the same plan. But both these writers designed their lenses for burning purposes only, and not for optical use on light, while all the surfaces of their lenses were spherical. In 1822 Fresnel constructed a built-up lens for lighthouse purposes, in which the centres of curvature of the different rings receded from the axis according to their distance from the centre, so as practically to eliminate spherical aberration, the only spherical surface left being the small central part *a* (fig. 13). These lenses are used for revolving lights only.

FIG. 12.

*Cylindrical Refractor.* This instrument was introduced by Fresnel Cylindric for effecting dioptrically by refraction in front of the flame what refractor.

had been done before catoptrically by Muret's reflector by reflection from behind the flame. It consisted of a zone or hoop of glass (figs. 14 and 15) generated by the revolution round a vertical axis of the middle section of the annular lens just described, which lens, on the other hand, being generated by the same profile round a horizontal axis, paralleled the rays in every plane, whereas the cylindric refractor does so in the vertical plane only.

FIG. 14. - Plan.

*Totally Reflecting Prisms.*

Present next conceived the admirable improvement of employing the principle of "total" or internal reflexion by glass prisms. The ray  $F_i$  (fig. 16) falling on a prismoidal ring,  $ABC$ , is, on falling on the side  $AC$  the critical, is totally reflect on the side  $BC$  at  $c$ , it und horizontally. The highest reflexion by  $AC$  must (in

Fig. 15. Vertical Section.

Prisms.

along AB, and after a second refraction at B emerge horizontally. The lowest ray EB after refraction by AB must, for like reason, pass along BC, and after reflexion by AC and a second refraction by BC also emerge horizontally. Every other ray incident on the prisms between A and B is, after one reflexion and two refractions, emitted horizontally.

**Straight Refracting Prism.**—Fresnel's straight refracting prism which refracts the rays that fall on it, but in one plane only, requires no further explanation, as it is simply a straight prism of the same horizontal cross section as one of the prisms of his cylindric refractor, so as when placed in front of his fixed apparatus to produce a beam of parallel rays like a lens.

**Great Central Lamp.**—We will now go on to describe the manner in which Fresnel utilized the four new optical agents which he originated, by first referring to his central burner system. In all lighthouses prior to 1822 the mode of getting up the required power was by employing a sufficient number of separate reflectors, each of which (unless we except Boucher-Moreau's mirror) required its own separate lamp. Instead of numerous independent lamps and reflectors, Fresnel used a single lamp which had four concentric wicks, and was fed with oil by a pump worked by clock work. Surrounding this burner was a stationary cylindric refractor for a fixed light, and annular lenses revolving outside of it for a revolving light.

#### Fresnel's Combinations of his Optical Agents.

**Catadioptric Fixed Light.**—This apparatus (figs. 17 and 18), in which a central burner is used, consists of a dioptric cylindric refractor with zones of silvered mirror above and below similar in profile to Boucher-Moreau's reflector. By the adoption of the

Fig. 17.—Section.

Fig. 18.—Plan.

refractor the whole of the wasteful divergence which occurs in Moreau's reflector is prevented. We have here a geometrically perfect combination, but it is not so physically, because metallic reflexion is used. This physical defect Fresnel obviated in his next design.

**Dioptric Fixed Light.** First Application of Total Reflexion to Fixed Light.—In this apparatus Fresnel substituted his totally

Fig. 19.—Elevation.

Fig. 20.—Vertical Section.

refracting prism *p* and lens *R* for Moreau's reflector, and thus concentrated the whole light equally over the horizon by means of optical agents alone. This was the first application of total

reflexion to lighthouse apparatus, and this beautiful instrument continues till now in universal use. Figs 19 and 20 represent an elevation and section of this apparatus.

**Fresnel's Revolving Light.**—In this form of revolving light (fig. 21) the central burner is surrounded by annular lenses *L*, and ing light.

Fig. 21.—Vertical Section.

All these optical agents are made to revolve round the central lamp, and the sailor receives a full flash when axis of one of the merging beams passes his eye, and as it passes him he is in darkness until the next beam comes round. This design, unlike that of his fixed light, is imperfect on account of the employment of metallic reflexion, and because two agents are employed for all except the central portion of the rays.

**Fixed Light varied by Fresnel's.** This distinction (figs. 22 and 23) Fresnel produced by placing his straight refracting prisms *p* on a revolving frame outside of his fixed light apparatus *rr*, so that when the upright prisms come in line with the observer the light is increased to the power of the revolving light, a broad flash as in the annular lens being produced in place of a narrow strip of rays as in the unassisted fixed light.

Fig. 22.—Plan.

Fig. 23.—Vertical Section.

#### Alan Stevenson's Improvements

Mr Stevenson was the first to introduce the dioptric system into Britain, and in doing so he made the following improvements.

1. **Refractor of a Truly Cylindrical Form.** Owing to difficulties in construction, Fresnel adopted a polygonal instead of a cylindric prism for his refractor, but Mr Stevenson succeeded in getting Messrs Cookson of Newcastle to construct a first order refractor of a truly cylindric form.

2. **Helical Glass Joints for Fixed Lights.**—Mr Stevenson further improved the apparatus by constructing the refractor in rhomboidal instead of rectangular pieces (figs. 24 and 25), thus producing helical joints and preventing serious obscuration of the light in any azimuth.

**Helical Metallic Framework.** The internal metallic framework for supporting the upper cupola of prisms was also, for the same reason, made by him of a helical form.

3. **Diamond Framed Lantern.** The astragals or arch bars of the lantern were likewise made

Fig. 24.—Elevation.

Fig. 25.—Vertical Section.

and constructed of bronze instead of iron in order to reduce their sectional area. A small harbour light with inclined astragals was made in 1836 by Mr E. Sang. Mr Stevenson also prepared a design in 1846 for Start Point, Orkney, in which he extended the helical arrangement to the astragals, but it was never carried out. Mr Douglass independently designed and afterwards carried into practice this form of lantern.

**Alan Stevenson's Improved Revolving Light for Skerryvore.**—In 1835 Mr Stevenson, in a report to the Northern Lighthouse Board, proposed to add fixed reflecting prisms *p* (fig. 26) below the lenses of Fresnel's revolving light, and he communicated this proposal to M. L. Fresnel, who approved of his suggestion, and

assisted in carrying out the design in 1843. This combination added, however, but little to the power of the flash, and produced both a periodically flashing and constantly fixed light; but it must be remembered that the prism for fixed lights was the only kind of reflecting prism then known. The combination of trapezoidal lenses and mirror, was also, for the same reason, still used. The prisms for Skerrevore were the first that were made of the large size (first order), and were constructed by M. Soleil at Paris under the superintendence of Leonor Fresnel, the successor of his brother Augustin, then deceased.

Besides the designs which have been described for improving Fresnel's revolving light, there were many others, among which may be mentioned those of Leonor Fresnel, Sir David Brewster, W. H. Barlow, F.R.S., A. Gordon, Lepaute, Letourneau, Reynaud, and Tabouret; but in all these, as well as in those which have been described, the rays were either not parallelized in every plane or else unnecessary agents were resorted to for that purpose.

#### T. Stevenson's HOLOPHOTAL System.

It was not till 1849-50 that the problem was first solved of condensing the whole sphere of rays diverging from a flame into a single beam of parallel rays without any unnecessary reflexions or refractions.

**Catadioptric Holophote.**—In figs. 27 and 28 part of the anterior hemisphere of rays is intercepted and at once parallelized by the

FIG. 27. -- Vertical Section.

FIG. 26. -- Vertical Section.

FIG. 28. Front Elevation.

lens L, whose principal focus (i.e., for parallel rays) is in the centre of the flame, while the remainder is intercepted and made parallel by the paraboloid a, and thus the double agent in Fresnel's design are dispensed with. The rays of the posterior hemisphere are reflected by the spherical mirror b back again through the focus, whence passing onwards one portion of them falls on the lens and the rest on the paraboloid, so as finally to emerge in union with and parallel to the front rays. This was the first instrument which intercepted and parallelized all the rays proceeding from a focal point by the minimum number of agents. It is therefore geometrically perfect, and was called by Mr Stevenson a holophote, but it is not physically so, for it employs metallic reflexion, and with an ordinary oil flame and burner some of the rays reflected by the spherical mirror would fall upon the burner and be lost. This instrument was first employed at the North Harbour of Peterhead in 1849.

**Holophotal Catadioptric Apparatus Revolving round a Central Flame.**—If in place of Fresnel's compound arrangement of trapezoidal lenses and plane mirrors there are substituted mirrors R, R (fig. 29) generated by the revolution of a parabolic profile round a horizontal axis, all the light will be at once sent out in parallel beams by them and the lenses L, and the apparatus is therefore geometrically perfect, but metallic instead of glass agents are still employed.

FIG. 29. Vertical Section.

#### T. Stevenson's Holophotal Dioptric Agents.

The agents for rendering the holophote purely dioptric fall next to be described.

**Holophotal Prisms, 1850.**—If prisms are generated by the revolution of sections of Fresnel's prisms round a horizontal instead of a vertical axis, as shown in fig. 30, rays incident upon them will be made parallel in every plane instead of in the vertical plane only as in Fresnel's prisms.

In 1852 it was stated that A. Fresnel, in 1826, tried prisms of this kind on lamp-posts for the quays of a canal in Paris, but their use was discontinued. They were not so arranged as to be applicable to lighthouses, and no account of them was published.

**Double Reflecting Prisms giving Two Internal Reflexions instead of One, 1850.** The object of these prisms is to reflect the rays back through the focus. The rays from F (fig. 31) pass normally through

FIG. 30.

FIG. 31. -- Vertical Section.

the surface bc and fall upon the surfaces ab, ac, by which they are totally reflected and sent back to the flame F.

#### Optical Combinations of Dioptric Holophotal Agents.

**Dioptric Holophote with Dioptric Spherical Mirror.** All rings of dioptric holophotal prisms p, p (fig. 32), combined with a central refracting holophotal lens L subtending together 180°, be placed before a flame, the whole with the front half of the diverging sphere of rays will be at once mirror.

condensed by refraction and total reflexion into one beam of parallel rays. Next, if there be placed behind the flame a dome of glass a formed of zones generated by the revolution of the cross section of the double reflecting prisms round a horizontal axis, the back hemisphere of rays will, after the double reflexion, be returned by it through the flame so as to diverge along with the front rays; for this dome is a perfect mirror, not only for the faint light that is superlatively reflected by the first concave surface, but also for the main portion of the rays which enter the substance of the glass and are there totally reflected. Thus the whole light is parallelized entirely by glass agents. This combination would therefore produce a light of maximum intensity, being both geometrically and physically perfect when the radius is a luminous point. Still, some of the rays reflected by the upper and lower parts of the mirror will not clear the burner of an oil light, but falling on it will be lost.

FIG. 32. -- Vertical Section.

**Dioptric Holophotal Revolving Light, Application of Total Reflexion to Revolving Lamps, 1850.** If sections of the revolution of light

the dioptric holophote be arranged as a polygonal case round a large central flame and made to circulate round that flame, a revolving light with its periodic flashes will be produced (fig. 33), which is therefore geometrically and physically perfect, and the double agents used in Fresnel's revolving light are thus wholly dispensed with. Mr J. T. Chance says, "on the whole the modern plan (holophotal) must give light five or six times more intense than that of the former (Fresnel's) arrangement." The greater simplicity and compactness of this light may be seen in comparing figs. 21 or 26 with fig. 33.

The holophotal revolving light is now the only one that is employed for all new lights. It was first introduced in 1850 on the small scale by Messrs Stevenson at Honsburgh Rock, Singapore, and on the larger scale at North Ronaldshay in Orkney, the prisms of which were most successfully made in 1851 by Letourneau of Paris.

FIG. 33. Elevation.

Fixed  
light  
with  
flashes.

**Holophotal Fixed Light varied by Flashes.**—Fresnel's double agents (figs. 22, 23) are here also dispensed with by the single agency of panels of fixed light apparatus  $p, p'$  (fig. 34) and cylindrical retractors  $L, L'$ , alternating with panels of holophotal apparatus  $p, p', L, L'$ , both of which revolve together round the central burner.

Back  
prisms.

**Back Prisms.**—It will be noticed that, while perfection was attained by single agency in Fresnel's fixed apparatus and also in the holophotal revolving apparatus, a physical defect still attached to every form of holophote which compressed the light into a single beam where the rays require to be sent back through the flame. The defect is not a geometric one, and would be non-existent were the luminant a mathematical point. In order to remedy this objection, Mr T. Stevenson and Mr Brebner designed what they termed "back" prisms capable of deviating the rays through an angle of  $130^\circ$ , so that the engineer becomes virtually independent of the critical angle. Professor Swan of St Andrews also independently proposed the same kind of prism, accompanied by general formulae for its construction. The ray  $ab$  (fig. 35) is refracted at  $b$ , totally re-

Fig. 35.

flected at  $c$ , and again refracted at  $d$ , so as to pass out parallel to the horizontal axis. These prisms may be formed by the revolution of the generating section round either a vertical or horizontal axis, or they may be made straight as shown in elevation and section in the diagram. The "back prisms" which were first used in Lslac, Argyllshire, were made by Messrs Chance in accordance with Professor Swan's formula.

Perfect  
form of  
holo-  
phote.

**Perfect Form of Dioptric Holophote for an Oil Flame.**—By combining the back prisms  $abc$ , fig. 35, just described with a semi-holophote  $abc$  subtending  $180^\circ$  and a portion of the dioptric spherical mirror  $gh$ , no light is lost on the burner, and all the rays are parallelized, so that this apparatus, being all of glass, is both geometrically and physically perfect.

Fig. 36. Vertical Section.

Chance's  
improvement.

**Chance's Improvement of 1862.**—Mr Chance says, "The principle of generating zones round a vertical axis instead of the horizontal axis is introduced by this author, who adopted it in the first

Section in line AB

complete catadioptric  
exhibition of 1862.

was made and was shown in the  
donors of Northern Lighthouses,

for whom it was constructed, in order to further the realizing of what Mr T. Stevenson had ingeniously suggested about twelve years previously. During the progress of this instrument the idea occurred to the author of separating the zones (fig. 37) and also dividing them into segments like the ordinary reflecting zones of a dioptric light; by this means it became practicable to increase considerably the radius of the mirror and thereby to render it applicable to the largest sea light without overstepping the limits of the angular breadths of the zones, and yet without being compelled to resort to glass of high refractive power.\*

Mr Stevenson states (*Min. Civ. Eng.*, vol. xxvi.) that he originally intended to generate the prisms round a vertical axis, but adopted the horizontal as more practicable where flint glass which was taken out of the melting pot on the end of a rod had to be employed for the most important and smaller central parts of the apparatus, which at that date were the only ones that could be constructed.

**Professor Swan's Designs.**—Among several ingenious arrangements and new forms of agents proposed by Professor Swan's designs,

the mode of sending rays from prisms through interstices left between other prisms placed in front, and also a form of agent which he termed the trisopteric prism, in which the rays would undergo two refractions and three reflexions. In fig. 38  $a$  are the front and  $b$  the trisopteric prisms. The two upper and lower prisms  $a$  are constructed of flint glass of high refractive power. It will be observed from the drawing that this ingenious arrangement is nevertheless open to objection, for cones of light of  $30^\circ$  in front and of  $65^\circ$  at the back are lost through the interstices.

Fig. 38. Vertical Section.

**T. Stevenson's Azimuthal Condensing System for Distributing the Light Unequally in Different Directions either Constantly or Periodically.**

Previous to 1850 all apparatus was designed to emit light of Condensed power in every azimuth either constantly or periodically, so that when applied to illuminate seas extending farther in some directions than in others, such, for example, as long narrow sounds, the power was either needlessly great in some azimuths or not nearly strong enough in others. The only exception was where a tower was placed on a long straight coast, when a spherical mirror was used behind the flame to prevent the light passing landward. The light that would have been lost on the land was, in this way, sent seaward, but no attempt was ever made to condense the light over a given area or to allocate this auxiliary light in proportion to the varying lengths of the different ranges and the amplitudes of the arc over which it had to be seen, nor, where a light had to show all round the horizon, to weaken its intensity in one arc and with the rays so abstracted to strengthen some other arc which from its nature being longer ought to be of greater power. As the

agents which we have described were insufficient for this purpose, it became necessary to devise new agents possessing peculiar properties for distributing the rays not equally but equitably. Some of the more important of these agents and their combinations will be described, but before doing so it is necessary to make some preliminary explanations.

The beam of the emergent light from a condensing apparatus is neither a solid beam of parallel rays like that from an annular lens nor yet a zone of rays diverging naturally in azimuth all round like that from an ordinary fixed apparatus, but is intermediate between these, being a solid angle or wedge of light strengthened by those rays which would naturally diverge in other directions, but which are diverted and spread over the given sector as shown perspective in plan in fig. 39, in which  $L$  represents the position of the lighthouse,  $LD'$

Fig. 39.

\* "Professor Swan's Designs," *Trans. Roy. Scot. Soc. of Arts*, 1867-68.

the range, or distance at sea from which the light can be seen, and  $DAD'$  the solid horizontal angle that is to be illuminated and into which all the light  $DAD'$  which would naturally diverge over the rest of the circle must be compressed, and over which it must be uniformly spread.

**Requirements for FIXED Condensing Lights.**—1. Where a light has to be seen constantly over only one arc of the horizon, the apparatus must compress all the rays within that one arc whatever its amplitude may be, and spread them uniformly over it.

2. Where the whole horizon has to be constantly illuminated, but the light has to be seen at greater distances over some parts of the sea than over others, as much light must be abstracted as can be spared from the shorter ranges and diverted to the longer so as to allocate the rays in the compound ratio of the number of degrees and the squares of the distances from which the light has to be seen in each arc; and the light thus diverted from one arc to strengthen another must be spread uniformly over the one that has to be strengthened. By this mode of abstraction and addition there is produced a constant equitabie distribution over the whole horizon of all the rays from any single flame. Where the whole horizon has not to be lighted, and where more than one arc has to be strengthened, the rays which would be lost on the land or can be spared in some other direction must be diverted to and spread uniformly over these arcs in proportion to their amplitudes and ranges.

**Requirements for REVOLVING Condensing Lights.** 1. Where a light has to give its flashes periodically over only one arc of the horizon, all the rays must be collected and sent out periodically in solid beams of equal power over that arc.

2. Where the whole horizon has to be periodically illuminated, but where its flashes have to be seen at greater distances over some parts of the sea than over others, the apparatus must be made (as in number 2 of the fixed condensing light) to vary proportionally the power of the flashes whenever they begin to pass over those parts of the sea where the ranges are of different lengths so as to produce an equitabie periodic distribution of all the rays.

3. Where the whole horizon has not to be lighted, and where more than one arc has to be strengthened, the rays which would be lost on the land or can be spared in some other direction must be diverted to and spread uniformly over these arcs so as to strengthen the flashes in proportion to their amplitudes and ranges.

If  $a$  be the number of degrees in an arc to be illuminated, and  $d$  the distance in miles to be traversed by the light, then, neglecting atmospheric absorption, the quantity of light to be allocated to that arc will be proportional to  $nd^2$ ; but if we take account of atmospheric absorption, supposing  $q$  to be the quantity out of a unit of transmitted light which escapes absorption after passing through a mile of air, then the whole light needed by the arc to be illuminated will be proportional to  $m \cdot nd^2q^d$ . Supposing now that  $L$  is the whole  $360^\circ$  of available light from the lantern, the quantity to be apportioned to the given arc will be  $\frac{L \cdot nd^2q^d}{\Sigma m}$ , where  $\Sigma m$  denotes the sum of the several numbers  $m$  computed for the respective arcs of the horizon.

## The Principal Optical Condensing Agents.

**Condensing Straight Prisms.** These, either by reflexion or refraction or both, cause a ray  $fr$  (fig. 40) proceeding in any compass

Fig. 40.

bearing from a fixed light apparatus  $AA$  to emerge in the direction, e.g., parallel to the corresponding ray  $fb$ , which proceeds in the same compass bearing from another part of the apparatus and so of any other ray  $fr$  which is bent parallel to the ray  $fa$ .

**Right-angled Expanding Prisms.** These (fig. 41) are right-angled vertically, while in *plano* two of them  $C_1C_2$  are semi-cylinders, and the third  $C_3$  a semi-cone. A semi-cylindric beam of parallel rays passing vertically upwards and falling normally on the bases  $a$  of the prisms enter the glass, are reflected

Fig. 41

by the sides  $b$ , and pass out horizontally and normally to the other sides; but, as the prisms are bent through a circular segment  $adad$  in *plano*, the emergent rays will be spread over the same angle in azimuth, and this will be true of any angle in azimuth subtended by the prisms. As those in the diagram subtend  $180^\circ$ , the light will in this case be spread over half the horizon  $dad$ .

**Two Prisms.**—These are for carrying out Professor Swan's mode of causing light coming from prisms behind to pass through spaces left for the purpose between others in front. The two prisms (fig. 42) are formed by cutting out the apex (shown black on diagram) of a straight prism so as to leave a sufficient space between it and the next prism for the passage of rays coming from behind. The length of glass traversed by the rays is lessened by this arrangement, and the size of the apparatus and lantern can at the same time be very greatly reduced.

Fig. 42.—Section.

**Differential Lens.** Horizontal divergence may be obtained to any required amount by varying the curvature of the inner focal lens and refractor.

Fig. 43.

Fig. 44.

The outer face (fig. 43) is the same as that of an ordinary annular lens, while the other face (fig. 44, though straight in the vertical, is ground to the required curve in the horizontal plane. The rays  $fr$  (fig. 45) falling upon the lens converge to the vertical focal plane  $ff'$  and afterwards diverge through the smaller horizontal angle  $a'f'a'$ , and so for any other case.

**Differential Refractor.** This is the application to the cylindrical refractor of the same principle which has been described above for the ordinary annular lens.

**Condensing Cylindrical Spherical Mirror.** If a large part of a spherical mirror be cut opposite to a short range of sea, and a smaller one be cut in the mirror opposite to the longer range which has to be strengthened, then the light passing through the larger cut is received on an elliptic reflector placed behind it, so as, with the help of an additional reflector and lens, to concentrate the larger cone of rays to be compressed into the smaller arc which has to be strengthened.

**Spherical Mirror of Unequal Area.** This may be cut down in height in such a way that its different heights represent inversely the different distances of the neighbouring land to the light-house, so as to reflect less light in the shorter and more in the longer ranges.

## Application to Fixed Condensing.

**Fixed Condensing Light for a Single Sector.** 1850. The heliophote light for  $pLp$  (fig. 46) throws its whole light on straight condensing prisms single sector, each of which distributes the rays over the required sector.

**Condensing Apparatus for Steamers' Side Lights.** By means of this application of the condensing principle (figs. 47 and 48) all the light can be distributed with strict equality over  $112^\circ 30'$ , which is the arc prescribed for steamers by the Board of Trade. Several of the Transatlantic and other steamers have adopted this kind of apparatus, which is hung below and placed in iron towers, having an entry from below the deck, which can be made use of in bad weather.

Fig. 46.—Vertical Section.

**Condensing Quadrant.** The fixed apparatus  $Bb$ , with a spherical condensing mirror behind, throws its rays directly through the arc of  $90^\circ$  of quadrant  $abf'$ , while the supplementary rays falling on the straight condensing prisms  $p, p', p''$  (fig. 49) are sent out parallel to the corresponding rays in the unobstructed central quadrant of the main apparatus. The whole light will therefore be spread over equally over  $90^\circ$ .

**Condensing Octant.**—The central fixed apparatus *bb* (figs. 50, 51) with spherical mirror *dd* throws its rays directly over the angle of  $45^\circ$  *ppp*, while the supplemental rays fall upon the straight condens-

vertically upwards, when, falling on the expanding prisms *gfe*, it also is finally spread over the required arc. Thus the whole light is condensed and distributed with strict equality over the  $45^\circ$  by means of six different optical agents. Two apparatus of this kind form the leading lights to the River Tay.

**Condensing Twin Prism Light.**—Fig. 52 shows part of the Lamplash light in the Firth of Clyde. Its action will be easily understood by the numbers shown on the diagram.

**Fixed Condensing Lights for more than one Sector of Unequal Range.**—Fig. 53 is a chart of the Sound

of Glenelg, in which the Isle Oronsay light has to be seen generally at a distance of 3 or 4 miles across the Sound, but in the direction AB down the sound an angle of  $10^\circ$  has to be seen about 15 miles and

FIG. 47.—Side Elevation.

ing prisms *p*, each of which spreads the incident rays parallel to the corresponding rays in the central angle *ppp*. In this way the whole of the front hemisphere of rays is parallelized in the vertical

FIG. 48.—Horizontal Section.

plane and spread equally over the  $45^\circ$  in azimuth. The hemisphere of back rays is condensed into the same arc seawards by the dioptric spherical mirror, which returns the rays incident upon it through

FIG. 49.—Horizontal Section.

FIG. 50.—Vertical Elevation.

the same, where mingling with the front rays they are finally distributed over the arc of  $45^\circ$ . The light passing over the spherical is parallelized by a half holophote *th* (fig. 50), and sent

FIG. 51.—Horizontal Section.

Condensing twin prism.

Lights for sectors of unequal range.

FIG. 52.—Horizontal Section.

another up the sound between C and D an angle of  $10^\circ$  has to be seen about 7 miles. Fig. 54 shows in plan the apparatus, which was for certain local reasons not constructed according to the

FIG. 53.

formula, but  $193^\circ$  of the spare light which would otherwise have fallen upon the land were allocated down Sleaf Sound and  $139^\circ$  down the Sound of Glenelg. That for Sleaf Sound was given

FIG. 54.—Horizontal Section.

FIG. 55.—Vertical Section.

directly by the main apparatus through the arc  $\beta$ , and that to Glenelg through the arc  $\beta$ , but these arcs were respectively strengthened by portions of the holophotes B and C, the light from which was condensed respectively over the arc  $\beta$  by each of the straight prisms *a* and over the arc  $\beta$  by each of the prisms *b*. The condensed light at Isle Oronsay, which is of the fourth order, appears to be equal to that of a first order, so that with a

lamp consuming annually only 170 gallons of oil a light is obtained in the only direction in which great power is required equal in effect to a lamp consuming 800 gallons per annum.

**Fixed Condensing Lights of Unequal Range which constantly illuminate the whole Horizon.**—For this purpose the condensing spherical mirror or spherical mirror of unequal area will be found applicable.

**Revolving or Intermittent Lights for Condensing the Rays into one Sector.**—The holophote in fig. 55 throws its rays on straight condensing prisms P, each of which spreads the light over the prescribed sectors, while masks M turning horizontally on pivots cut off the light either slowly or suddenly so as to produce a revolving or an intermittent light, both of which condense all the rays uniformly over the one sector.

**Application of Condensing Principle to Revolving Lights of Unequal Range, which do not illuminate the whole Horizon.**

**Repeating light.** **Repeating Light.**—Plane mirrors M (fig. 56) revolve on an endless chain placed outside of the apparatus and alter the direction of the

flashes after they pass into the dark arc on the landward side so as to cause the lenses L, L to repeat their flashes over the seaward arc which requires strengthening. The condensing spherical mirror and mirror of unequal areas will also be found applicable in cases where the flashes do not require to sweep over the whole horizon.

**Revolving lights.** **Condensing Revolving Lights which Periodically Illuminate the whole Horizon, but which Vary the Strength of the Flashes in Passing over Certain Sectors.**—The spherical mirror of unequal areas and the condensing mirror are equally well suited for those that revolve.

**Intermittent lights.** **Condensing Intermittent Lights.**—Figs. 57 and 58 show straight refracting or reflecting prisms, which revolve and intercept as they pass round certain fixed rays from a central fixed light apparatus so as to produce perfect darkness over the sectors which they subtend at the time, while they spread the rays which they intercept uniformly over and thus strengthen the intermediate sectors which are illuminated directly by the central apparatus. The peculiar property of this arrangement is that the power is increased in proportion to the duration of the intervening periods of darkness. Thus, neglecting the loss by absorption, &c., the power is doubled when the periods of light and darkness are equal, tripled when the dark periods are twice as long as the light, and so on in proportion, while in every case the rays are spread uniformly over each illuminated sector.

**Intermittent light with Differential Refractor.**—Figs. 59 and 60 show the new apparatus of Mull of Galloway in which ABA is the differential refractor, by the compound horizontal and vertical action of which single agent the whole condensing intermittent effect is produced, so that condensing prisms are done

away with opposite the central, which is the most important, part of the apparatus. The centre of the inner curve of the refractor is at O in fig. 60. Though there is no relative motion in this apparatus, every part of which revolves together, the parts may be arranged so that the condensers only move. This apparatus was constructed in the most satisfactory manner by Messrs Barbier & Fenelette, Paris.

**Attraction of Fixed to Intermittent Apparatus.**—Any existing fixed light can at once be made intermittent so as to show either equal or unequal periods by simply causing condensing prisms to circulate round it, while the power will be increased in proportion to the ratio of the duration of light to dark periods.

FIG. 60.

Change of fixed to intermittent apparatus.

## Beacons and Buoy.

Beacons in exposed situations are constructed sometimes of Beacons, stone, and cement-concrete or cement-rubble, but generally of cast-iron columns let into heavy base plates which are fixed to the rock by strong lewis bats. The small class iron beacons are generally of malleable iron and the larger of cast-iron, but steel or bronze might with advantage be used in very exposed places. Fig. 61 shows a first order cast-iron beacon as used in Scotland.

**T. Stevenson's Apparent Light.**—This kind of light is specially useful at places where there is a sunk rock with little sea-room round it, and at the mouths of harbours which must be closely hugged by vessels seeking entrance. It consists of certain forms of optical apparatus for reflecting and redistributing at a beacon placed on a submerged rock parallel rays which proceed from a lamp and apparatus placed on the land. An optical deception is thus produced, as the sailor naturally supposes that there is a lamp burning on the beacon itself. The first light of this kind, which has been in use since 1851, was placed in a beacon on a sunk reef in Stornoway Bay, and is shown pictorially in fig. 62. This light is 530 feet distant from the lighthouse where the lamp is placed. Others have since been established at Grangemouth, which is 535 feet from the light, and at lesser distances at the harbours of Ayr and Arbroath, at Odessa in the Black Sea, and at Gatcombe Head, Queensland.

**Beacon Lights.** Lamps without glass chimneys, as used in the Beacon early experiments with paraffin, and as used with gas in Pintel's lights, buoy, having iron tubes placed at certain distances above the flame, and supplied with very large cisterns of crystal oil, have been kept continuously burning in Scotland for about a month without trimming. These lamps are for rocks at sea which can only be reached when the weather is moderate.

**Illumination of Beacons by Gas to Produce a Fixed Light.**—A light near Port-Glasgow has been illuminated by gas since 1861. The tower is about 300 feet from the shore, and the supply and pressure of gas are regulated by self-acting arrangements on the shore.

FIG. 59.

**Intermittent light with Differential Refractor.**—Figs. 59 and 60 show the new apparatus of Mull of Galloway in which ABA is the differential refractor, by the compound horizontal and vertical action of which single agent the whole condensing intermittent effect is produced, so that condensing prisms are done

Pintsch's buoy. Pintsch's Gas Illuminated Buoy for Producing a Fixed Light.— sounds the whistle. It is said that an undulation of even 12 inches is sufficient to sound the whistle. These buoys are gas and water tight, and are charged to a pressure

FIG. 62.

of ten atmospheres. The buoy is filled with gas sufficient to burn night and day for three or four months; the burning pressure is kept constant by Pintsch's regulator. These buoys promise to be of great service, and have now been in use for more than a year at several places both in England and Scotland.

*Automatic Meter for Producing Intermittent Lights by the Flow of the Tides.*—In order to distinguish one buoy or beacon from another, Mr T. Stevenson has proposed to make the flow of the gas itself produce automatic intermittent action without using clockwork. The full flame continues to burn until the action of the meter reduces the supply, but leaves a small jet still burning in the sockets of the burner till the full flame is again produced. This meter has been tried successfully on shore for twenty eight hours consecutively.

*Uniform System of Beacons and Buoys.* The first proposal for dealing systematically with the colours of beacons and buoys was in 1828, when Mr R. Stevenson proposed for the navigation of the

FIG. 63. Courtenay's Automatic Buoy. A cylinder, 27 ft. 6 in. long; B, ball valve; C, manhole; D, buoy; E, diaphragm; F, ball valve; G, inlet valve; H, air compressor; I, outlet valve to buoy; J, manhole; K, steps; L, steps; M, steps; N, steps; O, steps; P, steps; Q, steps; R, steps; S, steps; T, steps; U, steps; V, steps; W, steps; X, steps; Y, steps; Z, steps.

river, both to starboard and port, should be taken on the starboard and port of the vessel, and going up the river. This system has since been adopted generally in the United Kingdom. In 1857 Admiral Fitz-Roy proposed a uniform system for all the coasts of the country, and it was carried out in Scotland by Mr A. Cunningham. A uniform system has been adopted in England by the Trinity House, and in 1879 Mr J. F. Campbell suggested what is now the system in use, that a buoy shall indicate by its shape and colour the nature of the obstruction, in which a vessel should avoid.

*Argand's Automatic Buoy.* This is a cylindrical form of buoy (fig. 63) first used in 1810. It has a vertical tube A projecting below the level of the water, on the upper part of which cylinder there is a valve N and also two inlet valves F, so that the rising and falling of the buoy draws in and expels the air alternately which

*Tolling of Bells by the Hydrostatic Tolling of Pressure of the Tide.*—In 1810 Mr R. Stevenson designed apparatus for tolling tide. A bell on the Carr Rock beacon, which was to have been effected by a float when ascending with the pressure of the flowing tide, when descending with the fall of the ebb tide and by means of a peculiar arrangement of weights for keeping the bell in action during the time of slack water.

#### Illuminants.

After Argand's ordinary single-wick oil illuminant, Fresnel still adhering to Argand's principle of the double air current intro-

duced two, three, and four concentric wick burners, Mr Alan Stevenson the five, and Mr Douglass the six wick burner. These burners are suitable for the consumption of animal and vegetable oils, which were in use in the various lighthouse services of the world till within the last few years. These oils are, however, superseded by hydrocarbons, which at one half the cost give an increased enormous intensity for an equal consumption, but they require a larger supply of air for their combustion, and consequently an improved form of burner. M. Marié in 1856 devised a single-wick burner for this purpose which gave good results, but many and all attempts to construct a multiple-wick mineral oil burner failed till 1868, when Captain Doty's form was devised.

By a happy choice of proportions in the various parts of his burner (fig. 64), and by the addition of an exterior cylinder surrounding the outer wick, and a central disk, both placed in such a manner as to throw a current of air into the flame at the right place, Captain Doty succeeded in producing single and multiple-wick hydrocarbon burners, which carry a flag of great luminous intensity and regularity. The following table gives the details of these burners, and also the candle power and consumption, as determined by Dr Stevenson Macadam:—

FIG. 64.

Wicks	Mean Diameter of Outer Wick - Inches	Height of intense part of Flame, excluding Tails, in Inches	Candle Power in Sperm Candles, each consuming 120 grs. Sperm per Hour.	Value of Light from Consumption of 1 Gallon of 1 lb Sperm.	Consumption per Hour in Gallons.
1-75	1	1	23-65	27-39	0148
	1 1/4	1 1/4	80-13	27-04	0508
	1 1/2	1 1/2	200-75	27-2	1262
	1 3/4	1 3/4	287-62	27-3	1801

Mr J. N. Douglass has also introduced a mineral oil burner, which, however, Doty claims as similar in principle to his. By igniting only half the number of wicks (the outer in a six-wick for instance) the power of the burner can be diminished by one half. This is Mr Douglass's lamp of single and double power for use in clear and foggy weather respectively.

The mineral oil employed most extensively in lighthouse illumination is Scotch paraffin. The specific gravity, which is a test of the relative richness of the oil, should be from 0.8 to 0.82 at 60° Fahr., and the flashing point or temperature at which it begins to evolve inflammable vapour should not be lower than 125° nor higher than 135° Fahr. The Board of Northern Lighthouses was the first lighthouse authority in Britain that adopted paraffin and Doty burners, and by doing so an annual saving of between £4500 and £5000 in the maintenance of the lights on the Scotch coast was effected.

Single-wick burners are supplied with oil from the cistern by the capillary action of the wick alone. But in the case of multiple-wick burners other methods must be employed to secure a sufficient supply. If the cistern be placed above the level of the top of the burner, the flow of the oil to the wick cases is effected by the direct

action of gravity, regulated by a contrivance which maintains a constant head. If, however, the cistern be placed below this level, either a *mechanical* lamp is employed, in which the oil is forced into the burner by pumps worked by clockwork, or a *moderator* lamp, in which this is effected by the pressure exerted by a weighted piston descending in a cylinder forming the cistern.

**Coal-Gas.**—Coal-gas was first used as a lighthouse illuminant at Salvo, near Trieste, in 1817. For many years it has been used in the harbour lights of Great Britain where in the neighbourhood of gas-works. Mr J. B. Wigham has designed a compound or crocus burner consisting of a group of twenty-eight vertical tubes, each carrying an ordinary double fish-tail burner, and the ignited gases issuing from all these jets unite into one large flame. Additional groups of twenty jets each can readily be arranged around the first, which forms a central nucleus, and in this way, depending on the state of the atmosphere, the power of the burner can be made to will 28, 48, 68, 88, or 108 jets. Fig. 65 shows the arrangement

Coal-gas

Fig. 65.

Fig. 66.

Fig. 67.

for 28 jets, and fig. 66 one for 108 jets. In his triflor or quadri-flor systems Mr Wigham places two, three, or four of the burners already described vertically one above the other (fig. 67), with lenses opposite to each. The following table gives the candle powers, &c., of Mr Wigham's burners.

Number of Jets.	Consumption of Candle Gas per Hour.	Candle Power in Specimen Candles, consumm. 150 grs. per Hour
28	51.4	129.6
48	93.2	8.240
68	116.3	1.4019
88	241.0	2.6880
108	308.0	2.923.0

The diameter of the 108-jet burner is 12 inches.

Electric light

**Faraday and Holmes's Magneto-Electric Light.** In 1853 Professor Holmes made the first magneto-electric machine for lighthouses, which was tried by the Trinity House in 1857, and the electric light was first shown to the mariner in 1858. The Trinity House subsequently introduced it at Dungeness in 1862 and at Souter Point in 1871. The optical apparatus for these lights was designed by Mr J. T. Chance. In 1869 Holmes constructed for the Trinity House a dynamo-electric machine (in which no permanent magnet is used), giving a light of about 2800 candles. The magneto-electric light of Holmes as exhibited from a third order dioptric apparatus at the South Foreland light has been estimated at 152,000 candles, or twenty times that of the old first order dioptric fixed white light. The following table shows the results which have been obtained by Dr Tyndall and Mr Douglass by the magneto-electric and dynamo-electric machines, tried at the South Foreland, 1876-77:

Name of Machines.	Co. d.	HP. Absorbed.	Revolutions per Minute.	Light produced per HP. at Stand and Candles.	Order of Merit
	£			Max.   Mean.	
Holmes's Magneto-Electric.....	550	3.2	400	476   476	6
Alliance do.	494	3.6	400	513   543	5
Gramme Dynamo-Electric (No. 1)...	320	5.3	420	1,257   758	4
Do. do. (No. 2)...	320	5.74	120	1,257   768	4
Siemens's do. (large)...	265	9.8	480	1,512   911	3
Do. do. (small, No. 58)...	100	3.5	850	1,582   954	2
Do. do. (small, No. 68)...	100	3.3	850	2,080   1,254	1
Two Holmes's Magneto-Electric ....	1,100	6.5	400	432   432	...
Two Gramme Dynamo.....	640	10.5	420	1,085   654	...
Two Siemens's do. (small, Nos 68 and 68).....	200	6.6	850	2,141   1,291	...

It must be kept in view that in the electric as well as in every other light the following requirements must be fulfilled:—(1) it shall be constantly in sight during those periods of time at which it is advertised to the mariner as being visible; (2) it shall be seen as far as possible in a thick and hazy atmosphere; (3) it shall constantly maintain the distinctive character of the station where it is employed so as not to be mistaken for another light; and (4), when revolving, its flashes shall remain long enough in view to let the sailor take the compass bearing of the light. The electric light practically fulfils all these conditions, and, when we consider its transcendent intensity, and the smallness of the luminous radiant which enables the engineer to adapt it to any required conditions far more strictly than oil light, we may certainly conclude that the electric is the best though the most costly of all illuminants.

The only question which has not yet been decided is whether an electric light of equal initial power will penetrate a hazy atmosphere as far as an oil light. Experiment made at Edinburgh in 1866 seemed to show that the highly distinctive flash of the electric light when acted on by optical apparatus is perhaps not so much due to a greater amount of light as to the more complete parallelism of the rays issuing from the smallness of the radiant. The apparatus of a small size which was first used both in England and France necessarily produced a wasteful vertical divergence, and has therefore been now justly discarded.

## Allard's Statistics of Lighthouse Apparatus.

The following useful formulae are taken from M. Allard's very valuable *Mémoire sur l'Éclairage de la Mer*, Paris, 1876.

**Consumption of Oil in Relation to Diameter of Burner.** If we denote the consumption of mineral oil in grains per hour, and the diameter of the burner in centimetres, then

$$c = 1.967m^2.$$

**Luminous Intensities.** A Candel burner consuming 40 grammes of coal oil per hour being taken as unity, if  $I$  denote the intensity for mineral oil in a burner of diameter  $d$  in centimetres, then

$$I = 0.22d^{2.1}.$$

**Luminous Intensities of Apparatus.** Loss due to Reflection, Absorption, and Framing of Apparatus. The loss due to surface reflexion on entering and leaving the glass may be valued at .050, .052, .058, .075, .120, .230, for angles of incidence respectively of 0°, 15°, 30°, 45°, 60°, 75°. In totally reflecting prism, the luminous ray suffers three deviations instead of two, therefore the above values should be multiplied by  $\frac{1}{2}$ .

The loss by absorption in the glass, although properly given by an exponential formula, may, with sufficient accuracy, be taken as .03 per centimetre of glass traversed.

The loss due to the horizontal joints of the lenses, and to the intervals between the reflecting times, varies from .02 to .03, or from .01 to .04, in passing from the first to the fifth order.

**Coefficients.** These are the ratios in which the intensity of the lamp is increased by the apparatus. When  $c$  is the coefficient,  $f$  the focal distance,  $d$  the diameter, and  $h$  the height of flame in a fixed light apparatus, they can, if expressed in centimetres, be calculated from the formula

$$m = \left( \frac{f}{h} \right)^{1.15}, \text{ or } m = 2.12 \left( \frac{f}{h} \right)^{1.15}.$$

**Annular Lens.** The intensity of an annular lens is obtained by multiplying that of the corresponding fixed light by  $\frac{\phi}{\alpha}$  where  $\phi$  is the angle subtended by the annular lens, and  $\alpha$  the horizontal semi-divergence. The intensity of light from an ordinary fixed light apparatus is increased 38 per cent. by the use of the dioptric spherical mirror.

## Distinctions of Lights.

The most important characteristic distinctions of lights are the Distinctions following:—(1) The *fixed light*. Two of these are sometimes shown together at different heights from the same tower. (2) The *revolving light*, which at equal and comparatively long periods comes slowly and gradually into full power, and then as gradually disappears. (3) The *flashing light*, which at short periods (such as a few seconds) comes very quickly, though gradually, into full power, and as quickly and gradually fades away, was first introduced by the late Mr Robert Stevenson in 1825. (4) The *coloured light*, which is obtained by using coloured media, and was first employed by Mills of Bridlington. (5) The *intermittent light*, introduced by the late Mr R. Stevenson in 1830, which bursts instantaneously into full power, and after remaining as a fixed light for a certain length of time is as suddenly eclipsed and succeeded by a dark period. When the periods are very short the intermittent is now

1 This result as to total reflexion is not in accordance with the experiments of Professor Potter, which, however, were made with a very finely polished prism made for optical purposes.

called an occulting light. (6) The *intermittent light of unequal periods*, first proposed by Mr R. L. Stevenson in 1871, showing from the same apparatus different durations of the dark periods with equal periods of light, such as fixed for 2" eclipsed 5", fixed 2" eclipsed for 2", and then, as at first, fixed for 2". (7) *Group flashing light*. This distinction consists in giving a series of groups of two or more flashes separated by short eclipses, the groups being separated from one another by a larger eclipse. Mr Wigham of Dublin first proposed this distinction, and applied it to a dioptric revolving apparatus illuminated by gas, the effect being produced by raising and lowering the gas as Mr Wilson of Truro had done in 1827. Dr Hopkinson produced the same effect optically and for any illuminant by altering the arrangement of the ordinary revolving apparatus. (8) *Fixed lights illuminating the whole horizon, but showing revolving or intermittent characteristics over small arcs*. These can be produced by masks arranged like venetian house blinds placed opposite the arc where the characteristic is to be different from the main light. This arrangement and No. 9 were lately proposed by Mr T. Stevenson. (9) *Intermittent flashing light*. This is produced by condensing prisms revolving round a fixed light apparatus. The flashing light continues giving its rapidly recurring flashes for a certain period, which is succeeded by a dark period. The light which is not required during the dark periods is condensed by the prisms so as to strengthen the light periods.

**Uniform System of Characteristics.**—Various modes of distinguishing lights have been at different times proposed, such as Balbag's, which represented the stations by numbers, and Sir W. Thomson's by the Morse alphabet, or dots and dashes; but the following results seem to show that the present system is satisfactory, while it is free from many objections to which the other modes are liable. The Board of Trade records of shipwrecks show that during the space of twenty years (1857 to 1876) 2716 vessels were wrecked by stranding on the coasts and islands of Scotland and the Isle of Man, and that of all these there were only twenty-six, and the great majority of them were small vessels, in which it was even alleged that the cause was a failure in identifying the distinctive characteristic of some one of the Northern lighthouses, and in one-third of these cases the sailors were foreigners, and made such glaring mistakes as taking a fixed light for a revolving light. It is surely more probable that in many of these cases they did not confound the characteristics at all, but really did not know what they were. But, waiving all these considerations, there were after all only about 1 per cent. of all the wrecks which were alleged to have been caused by mistaking one light for another.

**Power of Coloured Lights.**—Experiments, and particularly those of M. Reynaud, have shown that red of the same initial power as white penetrates a fog to a greater distance than the white, owing to the red rays not being so much dispersed by refraction. Experiments made at Edinburgh in 1868 show that a light should, before passing through red glass, have four and a half times the initial power of a white light. The same results have since been obtained by M. Allard of Paris.

An objection to all coloured lights is the fact that some persons are unable to detect any difference between certain colours. According to the experiments of Professor Hologuen on from sixty to seventy thousand persons in Europe and America, about 4.2 per cent. are congenitally colour-blind, and the commonest form of this defect is inability to distinguish between red and green, which are the only tints employed for lighthouse distinctions. This objection, however, must gradually lose its weight, as the Board of Trade has now adopted the "colours test" as part of their examinations for certificates in navigation.

**Distribution of Lights on a Coast.**—Mr Alan Stevenson gives the following as a few of the chief considerations which should guide us in the selection of sites and characteristic appearance of the lighthouses to be placed on a line of coast.

"1. The most prominent points of a line of coast, or those first made on *over-sea* voyages, should be first lighted; and the most powerful lights should be adapted to them, so that they may be discovered by the mariner as long as possible before his reaching land.

"2. So far as is consistent with a due attention to distinction, revolving light, of some description, which are necessarily more powerful than fixed light, should be employed at the outposts on a line of coast.

"3. Lights of purely identical character and appearance should not, if possible, occur within a less distance than 100 miles of each other on the same line of coast which is made by over-sea vessels.

"4. In all cases the distinction of colour should never be adopted except from absolute necessity.

"5. Fixed lights and others of less power may be more readily adopted in narrow seas, because the *range* of the lights in such situations is generally less than that of open sea-lights.

"6. In narrow seas also the distance between lights of the same appearance may often be safely reduced within much lower limits than is desirable for the greater sea-lights. Thus there are many instances in which the distance separating lights of the same

character need not exceed 50 miles; and peculiar cases occur in which even a much less separation between similar lights may be sufficient.

"7. Lights intended to guard vessels from reefs, shoals, or other dangers should, in every case where it is practicable, be placed *seaward* of the danger itself, as it is desirable that seamen be enabled to make the lights with confidence.

"8. Views of economy in the first cost of a lighthouse should never be permitted to interfere with placing it in the best possible position; and, when funds are deficient, it will generally be found that the wise course is to delay the work until a sum shall have been obtained sufficient for the erection of the lighthouse on the best site.

"9. The elevation of the lantern above the sea should not, if possible, for sea-lights, exceed 200 feet; and about 150 feet is sufficient, under almost any circumstances, to give the range which is required. Lights placed on high headlands are subject to be frequently wrapped in fog, and are often thereby rendered useless, at times when lights on a lower level might be perfectly efficient. But this rule must not, and indeed cannot, be strictly followed, especially on the British coast, where there are so many projecting cliffs, which, while they subject the lights placed on them to occasional obscuration by fog, would also entirely and permanently hide from view lights placed on the lower land adjoining them.

"10. The best position for a sea-light ought rarely to be neglected for the sake of the more immediate benefit of some neighbouring port, however important or influential; and the interests of navigation, as well as the true welfare of the port itself, will generally be much better served by placing the sea-light *where it ought to be*, and adding, on a smaller scale, such subsidiary lights as the channel leading to the entrance of the port may require.

"11. It may be held as a general maxim that the fewer lights that can be employed in the illumination of a coast the better, not only on the score of economy, but also of real efficiency. Every light needlessly erected may, in certain circumstances, become a source of confusion to the mariner; and in the event of another light being required in the neighbourhood, it becomes a *deduction* from the means of distinguishing it from the lights which existed previous to its establishment.

"12. Distinctions of lights, founded upon the minute estimation of intervals of time between flashes, and especially on the measurement of the duration of light and dark periods, are less satisfactory to the great majority of coasting seamen, and are more liable to derangement by atmospheric changes, than those distinctions which are founded on what may more properly be called the *characteristic appearance* of the lights, in which the times for the recurrence of certain appearances differ so widely from each other as not to require for their detection any very minute observation in a stormy night. Thus, for example, flashing lights of five seconds' interval, and revolving lights of half a minute, one minute, and two minutes, are much more characteristic than those which are distinguished from each other by intervals varying according to a slower series of 5", 10", 20", 40", &c.

"13. Harbour and local lights, which have a circumference of less than 10 miles, should generally be fixed instead of revolving; and in such cases, for the same reason, be safely distinguished by coloured lights.

"14. In many cases also, where they are to serve as guides into a narrow channel, the leading lights, which are used should, at the same time, be so arranged as to serve for a distinction from any neighbouring lights."

Table of Distances at which Objects can be seen at Sea, according to their respective elevations, and the elevation of the eye of the observer. Distances at which objects are visible.

Heights in Feet.	Distances in Geographical or Nautical Miles.	Heights in Feet.	Distances in Geographical or Nautical Miles.	Heights in Feet.	Distances in Geographical or Nautical Miles.
5	2.565	70	9.598	250	18.14
10	3.628	75	9.935	300	19.87
15	4.443	80	10.26	350	21.46
20	5.136	85	10.57	400	22.9
25	5.736	90	10.88	450	24.33
30	6.283	95	11.18	500	25.65
35	6.787	100	11.47	550	26.90
40	7.255	110	12.08	600	28.10

Distribution of lights.

### *Floating Lights.*

**Floating lights.** Prior to 1807 the only kind of floating light was a ship with small lanterns suspended from the yard-arms or frames. The late Mr Robert Stevenson introduced in that year a lantern which sur-

rounded the mast of the vessel, and was capable of being lowered down to the deck to be trimmed. By his plan a lantern of much greater size could be used, and with this increase of size a larger and more perfect apparatus could be employed which admitted of gearing for working a revolving light, as adopted by the Trinity House. In fig. 68, *aa* is the mast, *b* tackle hook, *c, c* brass flanges for fixing parts of lantern together, *e* and *g* weather guards, *h* plate glass front of lantern, *i* shutter by which lamps are trimmed, *k* lamps, *l* silver reflector. Revolving catoptric apparatus was applied to floating lights in England, and M. Lecomte, in 1851, proposed to employ a number of sets of dioptric apparatus in one lantern; figs. 69 and 70 show elevation and plan of one of the Hooghly floating lights on the dioptric principle, designed for the Indian Government by Messrs Stevenson. It will be observed that not fewer than four of the separate lights are always in view from every part of the compass at once.

**Lanterns.** *Lanterns* are generally constructed of diagonally framed astragals (fig. 71) to avoid the obscuration of light in any one azimuth as would be the case with dioptric fixed light apparatus were vertical astragals used. The astragals are made of gun-metal, having a tensile strain of 33,000 lb to the square inch; the dome is made of copper plates rivetted

together; and the glass is the best plate  $\frac{1}{4}$  inch thick. Storm panes are kept at hand which can be applied in a few minutes in the event of a pane being broken, which sometimes occurs from large birds driving against the lantern and by stones thrown up from the face of cliffs by sea and wind during storms. Mr Douglass's cylindrical or helical lanterns (fig. 72) have steel astragals, and the panes, which are also cylindrical, are  $\frac{1}{4}$  inch thick.

**Machinery.**—Involving lights are provided by clock-work Machinery actuated by a falling weight. The machines are provided with a maintaining power which keeps the apparatus moving while the machine is being wound up, and a bell is attached which rings to warn the keepers when the machine requires winding up. A clock face is also attached which keeps time with the lightroom clock when the apparatus is revolving at the proper speed.

**Masking Screens.**—For the purpose of *cutting off* sharply the light proceeding from any fixed light apparatus, the late Mr. J. M. Bolton devised what he called radial masking screens. These screens, which are in use at several lighthouses where the farway far-chips is narrow, consist of a series of thin plates placed with their edges towards the apparatus, and with such a distance between them, and of such a length as will secure that only rays having the desired divergence can pass through between them.

With revolving lights it is not possible to effect a "cut off" as in the case of fixed lights, on any particular bearing; for the direction of the axis of the luminous beam projected by the lens or reflector is being continually changed in the horizontal plane by the revolution of the frame on which it is axed. Mr. Stevenson's mode of overcoming this difficulty is by fixing a light metallic screen or coloured glass shade outside of the revolving apparatus and on the safety side of the danger arc. These screens are fitted with rollers for running on a slightly inclined plane or camber path. Small projecting rods or sings fixed to the sides of each lens are, in revolving, brought against the edge of the screen, and gradually press the screen before it up the inclined plane. By the time the lens reaches the edge of the danger arc the screen has been pushed to the top of the inclined plane, and the full beam of light, coming from the now entirely uncovered lens, points in the required line of cut off, which is the border of the danger arc. But whenever the further revolution of the apparatus causes the sings to pass clear of the edges of the screen so as to free it from their pressure it immediately runs back again to its original position in front of the lens, so as to prevent any of the light being now sent seawards. By this continued reciprocal movement of the screen, as lens after lens comes round, the same effect will be successively produced and the light will always be cut off on the lines of observation, so that the flashes can never be seen within the danger arc.

**LIGHTING, ELECTRIC.** Artificial light is generally produced by raising some body to a high temperature. If the temperature of a solid body be greater than that of surrounding bodies it parts with some of its energy in the form of radiation. Whilst the temperature is low these radiations are not of a kind to which the eye is sensitive; they are exclusively radiations less refrangible and of greater wave-length than red light, and may be called infra-red. As the temperature is increased the infra-red radiations increase, but presently there are added radiations which the eye perceives as red light. As the temperature is further increased, the red light increases, and yellow, green, and blue rays are successively thrown off. On pushing the temperature to a still higher point, radiations of a wave-length shorter even than violet light are produced, to which the eye is insensitive, but which act strongly on certain chemical substances; these may be called ultra-violet rays. It is thus seen that a very hot body in general throws out rays of various wave-length, our eyes, it so happens, being only sensitive to certain of these, viz., those not very long and not very short, and that the hotter the body the more of every kind of radiation will it throw out, but the proportion of short waves to long waves becomes vastly greater as the temperature is increased. The problem of the artificial production of light with economy of energy is the same as that of raising some body to such a temperature that it shall give as large a proportion as possible of those rays which the eye happens to be capable of feeling. For practical purposes this temperature is the highest temperature we can produce. As an illustration of the luminous effect of the high temperature produced by converting other forms of energy into heat within a small space, consider the following statements. 120 cubic feet of 15 candle gas will, if burned in ordinary gas burners, give a light of 360 standard candles for one hour. The heat produced by the combustion is equivalent to about 60 million foot-pounds. If this gas be burned in a gas-engine, about 8 million foot-pounds of useful work will be done outside the engine, or four horse power for one hour. This is sufficient to drive an "A" Gramme machine for one hour; the energy of the current will be about 6,400,000 foot-pounds per hour, about half of which, or only 3,200,000 foot-pounds, is converted into radiant energy in the electric arc, but this electric arc will radiate a light of 2000 candles when viewed horizontally, and two or three times as much when viewed from below. Hence 3 million foot-pounds changed to heat in the electric arc may be said roughly to affect our eyes six times as much as 60 million foot pounds changed to heat in an ordinary gas burner.<sup>1</sup> Owing to the high temperature at which it remains solid, and to its great emissive power, the radiant body used for artificial illumination is nearly always some form of carbon.

The consideration of electric lighting naturally divides into two parts—the production of suitable electric currents, and the conversion of the energy of such currents into radiations. Although electric lights were first produced from currents generated by batteries, they have only attained commercial importance by the use of machines for converting mechanical energy into electric current.

*Dynamo-Electric Machines.* In the widest sense a dynamo-electric machine may be defined as an apparatus for converting mechanical energy into the energy of electrostatic charge, or mechanical power into its equivalent electric current through a conductor. Under this definition would be included the electrophorus and all frictional machines<sup>2</sup> but the term is used in a more restricted sense

for those machines which produce electric currents by the motion of conductors in a magnetic field, or by the motion of a magnetic field in the neighbourhood of a conductor. The general laws of electromagnetic induction need not be set forth here; as they are fully explained in the article **ELECTRICITY**, they will be assumed in all that follows. Since, if the current in a closed circuit be in one direction when the number of lines of force is increasing, it will be in the opposite direction when they are diminishing, it is clear that the current in each part of the circuit which passes through the magnetic field must be alternate in direction. Hence also the current in the wire outside the machine must also be alternate, unless something of the nature of a commutator be employed to reverse the connexions of the internal wires, in which the current is induced, and the external circuit. We have then broadly two classes of dynamo-electric machines:—the simplest, the alternate current machine,<sup>3</sup> where no commutator is used; and the continuous current, in which a commutator is used to change the connexions to the external circuit just at the moment when the direction of the current would change.

The mathematical theory of alternate current machines is comparatively simple.<sup>3</sup> Let  $\tau$  be the period of the machine, that is, the time taken to move the armature from one position to the next exactly similar position, e.g., in a Siemens alternate current machine of sixteen magnets on each side, one-eighth of the time of revolution; let  $\gamma$  be the coefficient of self-induction of the whole circuit, and  $R$  the resistance of the whole circuit; and let  $t$  denote the time at any instant counting from any epoch as initial, and  $I$  the magnetic induction at time  $t$  multiplied by the number of convolutions. The electromotive force in the circuit at time  $t$  will be

$$\frac{dI}{dt};$$

and the equation of the current will be

$$dI + RI = \dots$$

where  $x$  is the current. Now  $I$  may be expressed in the form

$$\sum A_i \sin 2\pi s_i \frac{t}{\tau},$$

where  $A_i$  and  $t_i$  are constants for the machine with given excitation of the fixed magnets. Hence

$$\gamma \frac{dI}{dt} + RI = \sum A_i \frac{2\pi s_i}{\tau} \cos 2\pi s_i \frac{t}{\tau},$$

$$I = C e^{-\frac{Rt}{\gamma}} + \sum \frac{A_i}{\tau} \frac{\sin 2\pi s_i \frac{t}{\tau}}{\sqrt{\left(\frac{2\pi s_i \gamma}{\tau}\right)^2 + R^2}},$$

where

$$\tan \frac{2\pi s_i \tau}{T} = \frac{2\pi s_i \gamma}{RT}.$$

The term  $C e^{-\frac{Rt}{\gamma}}$  is unimportant except just after closing the circuit. In the Siemens machine M. Joubert states that the only

<sup>1</sup> For descriptions of various alternate current machines, consult the following authorities: ALLIANCE: H. Fontaine, *Éclairage à l'Électricité*, Paris, 1879, p. 114; Dr H. <sup>2</sup> *Journal de Physique*, x. 141; Joubert, "Théorie des machines à courants alternatifs," in *Phil. Mag.*, x. 298, 384.

<sup>3</sup> *Proc. Inst. C. E. En.* 69, *Report from the Select Committee on Electric Lighting*, 1879.

important term is that of longest period. Hence, properly choosing the epoch, we write

$$2\pi A \frac{\cos 2\pi \frac{t}{T}}{T} \sqrt{\left(\frac{2\pi\gamma}{T}\right)^2 + R^2},$$

where

$$\tan \frac{2\pi\tau}{T} = \frac{2\pi\gamma}{RT}.$$

Hence we see the current is diminished either by increasing  $\gamma$  or increasing  $R$ , also that the moment of reversal of current is not coincident with that of no electromotive force, but occurs after that time by an amount depending on the relative magnitudes of  $\gamma$  and  $R$ . This explains in a general way what is known as the lead of the brushes in a continuous current machine. If we wished to apply a commutator to the Siemens alternate current machine for the purpose of producing an external current constant in direction, the change effected by the commutator should occur at an epoch after that of greatest electromotive force, an epoch which, with varying external resistance or varying speed, will depend on the resistance and speed.

The power of the current is  $Ri^2$ , and the energy in any considerable time,  $\Theta$ , is

$$\Theta R \frac{2\pi^2 A^2}{T^2} \left( \frac{1}{T} \right)$$

which shows that most power will be required to drive the machine when

$$R = \frac{2\pi\gamma}{T}$$

In what precedes it has been assumed that the copper wires are the only conducting bodies moving in the magnetic field. In most cases the moving wire coils of these machines have iron cores, the iron being in some cases solid, in others more or less divided. It is found that if such machines are run on open circuit the iron becomes hot, very much hotter than when the circuit of the copper wire is closed; in some cases the phenomenon is so marked that the machine actually takes more to drive it when the circuit is quite open than when the machine is short-circuited. The explanation is that on open circuit currents are induced in the iron core, but that when the copper coils are closed the current in the latter by its induction diminishes the current in the iron. The effect of currents in the iron cores is not alone to waste energy and heat the machine; the current produced is also actually less for a given intensity of field and speed of revolution. The cure of the evil is to subdivide the moving iron as much as possible in directions perpendicular to those in which the current tends to circulate.

**Continuous or Direct Current Machines.**—It has been shown that to produce a continuous current a commutator is needed. If there is but a single wire in the armature, or if there are more than one, but all are under maximum electromotive force at the same time, the current outside the machine, though always in the same direction, will be far from uniform. This irregularity may be reduced to any extent by multiplying the wires of the armature, giving each its own connexion to the outer circuit, and so placing them that the electromotive force attains a maximum successively in the several circuits. A practically uniform electric current was first commercially produced with the ring armature of Pacinotti as perfected by Gramme. Suppose a straight bar electromagnet surrounded by a coil of copper wire from end to end. Let the electromagnet be bent with the copper wire upon it until its ends meet and it forms an annulus or anchor ring. Let the two ends of the copper wire be connected, so that the iron core is surrounded by an endless copper wire, and you have the Pacinotti or Gramme ring. This ring rotates about its axis of figure between two diametrically opposed magnetic poles of opposite name. The ring may at any instant be supposed divided in halves by a diameter perpendicular to the diameter joining the centre of the poles. Equal and opposite electromotive forces act on the copper wire of the two halves, giving two opposite electric poles half way between the magnetic poles. If electric connexions could be maintained with these two points as the ring revolves, a continuous current would be drawn off. In practice this

is only approximated to. The copper wire is divided into a series of equal sections, and at the point of junction of each section with its neighbour a connexion is made with a plate of a commutator, having as many divisions as there are divisions of the copper coil. Collecting brushes bear upon the commutator plates, which are connected to the coil nearest to the point of maximum potential. Owing to the self-induction and mutual induction of the several coils of the armature, this point is displaced in the direction of rotation when a current is being drawn off, to an extent greater as the current is greater in relation to the strength of the magnetic field. The magnetic field in the Gramme and other continuous dynamo electric machines may be produced in several ways.<sup>1</sup> Permanent magnets of steel may be used, as in the smaller machines now made, and in all the earlier machines; these are frequently called magneto-machines.<sup>2</sup> Else

excited by a current from a smaller dynamo electric machine, were introduced by Wilde; these may be described shortly as dynamos with separate exciters. The plan of using the whole circuit from the armature of the machine itself for exciting the magnets was proposed almost simultaneously by Siemens, Wheatstone, and S. A. Varley.<sup>3</sup> For some purposes it is advantageous to divide the current from the armature, sending the greater part through the external circuit, and a smaller portion through the electromagnet, which is then of very much higher resistance, as the electromagnet is a shunt to the external circuit.

Each of these machines is called a shunt dynamo.<sup>4</sup> The last two arrangements depend on residual magnetism to initiate the current, and below a certain speed of rotation give no practically useful electromotive force.

In discussing the comparative efficiency of these machines there are two points to be examined. (1) How much of the power applied is converted into energy of current in the whole circuit, whether external or in the wires of the armature or of the electromagnets, and (2) how much of the power is available outside of the machine. The

practical sources of loss are friction of bearings, and of the brushes on the commutator, electric currents induced in the iron of the machine, production of heat in the copper wire of the armature due to its resistance, and production of heat in the wire of the electromagnet due to its resistance. There is also a certain loss in sparks upon the commutator. The currents in the iron are reduced by dividing the iron by insulating surfaces perpendicular to the electromotive force tending to produce such currents. The loss by resistance of wire in armature and magnets greatly depends on the dimensions of the machine. For imagine two exactly similar dynamo-electric machines, the one being  $n$  times the dimensions of the other, we have the following relations between them, assuming the same magnetic field per square centimetre, and the same speed of rotation:—

The electric resistances of the several parts are as  $1:n$ ;

The electromotive force of the armature as  $n^2$ ;

Current round magnets required to produce the field as  $n$ .

Thus the work wasted in heating the wire of the electromagnets varies as the linear dimensions of the machine. The current which the armature can carry with safety to the insulation will increase more rapidly than the linear dimensions of the machines, but less rapidly than the square of the linear dimensions. If the current vary as the linear dimensions  $n$ , the whole electric work done by the machine will vary as its weight  $n^3$ , and the work wasted in the coils both of the electromagnets and of the armature will only vary as  $n$ , showing a great theoretic advantage in favour of the larger machines.

*Electric Lamps. Incandescent Lamp.*<sup>1</sup>—The simplest way of obtaining light from an electric current is by passing it through a considerable resistance in such small compass that the conductor becomes intensely hot. It is of course necessary that the conductor shall be able to endure a very high temperature without injury. Iridium and platinum-iridium wire have been employed, but are too expensive for commercial use. Hitherto the only available substance is carbon, in the form of a thread or filament. This carbon must be protected from the air by enclosing it in a glass globe from which every trace of air has been removed. An electric current passing through a carbon filament obeys Ohm's law, as through a metallic wire. But in metals the resistance increases as the temperature rises, in carbon it diminishes.<sup>2</sup> The filament or thread of carbon being enclosed in a vacuum space, the energy of current converted into heat in the filament only leaves it in the shape of radiations. To light economically, it is necessary to heat the filament to such a temperature that the greatest possible proportion of these radiations shall belong to that part of the spectrum to which the eye is sensitive, i.e., to the highest temperature the filament will stand. The fundamental problem of incandescent electric lighting is to produce a carbon thread the substance of which shall permanently stand the highest possible temperature, to make good electrical connexion between the ends of the filament and the conducting wires, and above all to secure that the thread shall be uniform throughout its length, for the current which can be safely used is limited by the weakest point of the filament. Several inventors have recently succeeded in meeting these

conditions, but their relative merit and priority cannot be discussed here.<sup>3</sup>

*Semi-incandescent Lamp.*—The lamps of Werdermann, Reynier, and Joel are intermediate between arc lamps and incandescent lamps, and present the distinctive advantages of neither.<sup>4</sup>

*Arc Lights.*—Sir Humphry Davy discovered that if two pieces of carbon were placed in contact with each other, and the current from a battery of a sufficient number of elements were passed from one piece to the other, the current did not cease when the carbons were slightly parted, but that the current passed across the intervening space, causing an intensely high temperature and consequently brilliant light. The pieces of carbon gradually burned away, the positive carbon being consumed more rapidly than the negative. When an electric current passes through a conducting solid body maintained at a constant temperature, the difference of potential on the two sides of the body has a constant ratio to the current passing through; this constant ratio is known as the electric resistance of the body at its then temperature. No such constant ratio exists in the case of the electric arc. If you increase the current passing between two carbons at a small distance apart, you do not materially change the difference of potential at the two ends of the electric arc. It is, therefore, not strictly appropriate to speak of the resistance of the electric arc; the appropriate constant, or approximate constant, for an electric arc is the difference of potential between the two sides of the arc.<sup>5</sup> However near the carbons approach without touching, this does not fall below a certain minimum value, and as the carbons are separated its value increases. In ordinary practice with continuous currents the potential of the electric arc may be taken as ranging from 35 to 45 volts. If the current in amperes be multiplied by the difference of potential in volts, and the product be divided by 746, we have the power used in the arc itself in horse-power, that is, the power effectively used in lighting. The mechanism of an electric lamp has two functions to perform, it has first to bring the carbons into contact and then part them, or simply part them if they are initially in contact when the light is started, or when it is accidentally extinguished (this is called striking the arc); it has also to bring the carbons together as they are consumed. The former function is always accomplished by an electric magnet or solenoid. In the electric candles, e.g., those of Jablochkoff, Rapiéff, Wildo, or Siemens, the carbons are approximately parallel, and they burn down as does a candle,—the arc being forced to the ends of the carbons by the repulsion of the current in the carbons on the electric arc.<sup>6</sup> In the ordinary arc lamps the carbons have their axes in the same line, and their approach or recession must be controlled by the current passing through, by the difference of potential, or by both combined. When the same current passes through a succession of lamps in series, it is clear that the regulation cannot be by the

<sup>1</sup> The application of incandescent lighting on a large scale has been thoroughly worked out in all its details by Edison. For a description of the whole system see *Engineering*, xxxiii. 226, 250, 305, 407.

current alone, as this is the same for all the lamps, and might be maintained constant by the adjustment of any one only of the lamps. When lamps are burned in series, it is essential that the difference of potential shall be an element in the control. This is done by using an electromagnet bound by fine wire so as to have a resistance of some hundreds of ohms, and connecting it to the two sides of the arc. In the Siemens differential lamp, and in some others, a potential or shunt coil and a current coil oppose each other; as the arc lengthens the current becomes less, and the potential greater, each acting to cause the carbons to approach. It will be seen that the possible combinations of mechanisms and electromagnets for adjusting an electric arc are endless; and so also are the patents for such combinations.<sup>1</sup> When an alternate current is used for an electric arc, the phenomena are much more complicated, owing to the difference of potential being a discontinuous function of the time. The difference of potential will be (say) 40 volts in one direction for a certain fraction less than half of the periodic time of the current; the current then entirely ceases, generally for a finite time, and is then reversed with a sudden reversal of difference of potential.<sup>2</sup> The work done in the arc is measured by the time integral of the product of difference of potential and current passing. A knowledge of neither the mean strength of the current, nor of the difference of potential, nor of both, gives the means of ascertaining the work done in an arc with alternate current. The only satisfactory electrical method is the quadrant electrometer suitably connected, and this is open to the objection that a considerable resistance must be introduced into the circuit.

*Electric Light Measurements.*—Under this head we content ourselves with a warning. A bare statement that an electric arc light is of so many candle power really conveys no accurate information at all. The light from an electric arc differs greatly in colour from that of a candle;<sup>3</sup> a given arc light may have three thousand times as much red of a certain wave-length as a standard candle has of the same wave-length, but ten thousand times as much green light. Any one will admit that green light is not measurable in terms of red light; a mixture of red and green is not

measurable in terms of another mixture in which the proportions of the colours are wholly different. Again, the intensity of the light obtained from an arc light depends greatly on the direction in which it is viewed.<sup>4</sup> Neither of these considerations applies in the same degree to incandescent lamps. (J. HO.)

**LIGHTNING.** See METEOROLOGY and THUNDER-STORMS.

**LIGHTNING CONDUCTOR, or LIGHTNING ROD** (*Paratonnerre, Blitz-ableiter*), is the name usually given to apparatus designed to protect buildings or ships from the destructive effects of lightning. The title, alike in English, French, and German, is misleading; for, when properly constructed, lightning rods serve rather to prevent the occurrence than to ward off the effects of a flash of lightning. Damping the enemy's powder would be a most efficient precaution against cannon shot, but it would be very inappropriately termed fortification. When a conductor charged with electricity is brought near to another conductor connected with the earth, it induces on it a charge of the opposite kind of electricity. The result is an attractive force which tends to bring the conductors nearer to one another, and to augment the electric density on their opposed surfaces. When the density is sufficiently great, there is rupture of the dielectric (air) between the conductors, and the disruptive discharge takes place as an electric spark. If one of the conductors have projecting points or angles, the electric density is usually much greater at such places than over the rest of the surface. But, though the density is great at such places, the charge on them is usually small, and the discharge takes place in an almost continuous manner by a brush or glow. When, for instance, a large conductor, connected with an electric machine, is giving a rapid succession of bright sparks to a ball connected with the ground, the sparks cease as soon as a pointed wire, connected with the ground, is held in the vicinity of the conductor. No discharge is heard, but in the dark a faint glow is seen at the end of the wire, which continues as long as the machine is turned. Remove the wire and the sparks instantly recommence. This glow is known to sailors as St Elmo's (San Telmo's) fire, in old days Castor and Pollux (Min., H. N., ii. 37). Suppose now one of the conductors to be a thundercloud, the other the surface of the earth, the discharge will usually take place between the places of greatest surface density; and it will in general be the more gradual as these are more pointed, and of less capacity. Hence Franklin's idea of furnishing buildings or other prominent objects with a projecting metal spike well connected with the ground, for the purpose of preventing a lightning discharge by substituting for it what is practically a continuous electric current.

To effect this object thoroughly, only three things are necessary:—(1) the points should so project from the building or ship to be protected as to prevent any great development of electric density elsewhere than on themselves; (2) they should be effectually connected with the earth; (3) the connecting rod ought to be so good a conductor as not to be injured even by a powerful electric discharge.

The first of these conditions is realized by making the rod branch out to all the salient portions of the building or ship, and furnishing it with points projecting beyond each of them. No general rule can be laid down as to the extent of the region protected by a single point, though it may usually be assumed with safety that the region extends throughout a vertical cone whose vertex is at the point,

and whose semivertical angle is about  $45^\circ$ . This is probably not true if the point be very high, — on the top of a tall chimney or tower, for instance. Objects not far from the base of such a protected tower, and within the cone just described, have occasionally been damaged by lightning.

The second condition is easily fulfilled in towns by connecting the lower end of the rod with the iron gas and water mains, which form an excellent "earth," as it is technically called. Water pipes, being usually jointed with metallic lead washers, are preferable to gas-pipes, which are usually put together with white lead. This condition is also easy to secure in ships and in lighthouses, where large metal plates (in the case of a ship, the copper sheathing is precisely what is required) can easily be permanently immersed in sea-water. In country houses it is usually more difficult to obtain a proper earth. Plates and tubes of metal, of large surface, buried in ground which is permanently damp, form usually the best arrangement. A well makes a good earth; a carefully constructed water tank (of stone or cement) is not an earth at all.

The third condition, so far as experience can guide us, seems to be effectually realized by making the conductor throughout of iron rod of an inch in diameter, or of copper rod not less in diameter than  $\frac{1}{16}$ ths of an inch. Such rods of equal length have nearly the same conducting power, and therefore would have equal amounts of heat developed in them by a given discharge. But if such a discharge took place, the copper would be heated much more than the iron, in consequence of its smaller mass per foot (the specific heat being approximately the same in the two materials). Hence iron is, in this respect, preferable to copper, if the conducting powers of the rods are equal. Another advantage possessed by the iron rod is that it is much less likely to be wilfully damaged or stolen. Against this may be set the objections that it is easily injured by rust, and is not nearly so flexible as the equivalent copper rod. Conductors are now usually made of wire rope, so that the question of flexibility is no longer of serious importance; but when iron is used it should always be protected by zinc, *i.e.*, be what is absurdly called "galvanized." Many fantastic forms of lightning rods were devised in consequence of the old erroneous notion that their efficiency depended on their surface and not on their cross section. In reality all conductors of equal length, and of the same material, are equally efficient if their cross sections be equal.<sup>1</sup> Thus, instead of stating the diameter of a rod, we may speak of its weight per foot, and say that a copper conductor should weigh at least about half a pound, and an iron one at least two pounds and a half per foot, — provided the materials be of good conducting quality.

The points need not be very sharp, but they ought to be protected by a coating of platinum or other non-oxidizable metal. And they should be in a group of two or three at the end of each branch of the rod, lest one of them should be fastened or impaired in efficiency by an accumulation of electricity so rapid as to make the silent continuous discharge impossible. Joints should be avoided as far as possible; where they are unavoidable they should be made, not by screw or bolting, but by means of a large mass of solder completely enveloping the ends to be connected.

Another point to be carefully attended to is that all large metallic bodies, such as lead or zinc roofing, metal tanks, &c., should be in good conducting connexion with the rod, so as to prevent discharges of electricity inside the ship or building. In many buildings we see the lightning rods

attached by means of glass or porcelain insulators, such as are employed for telegraph wires. This is a perfectly needless, expensive, and possibly dangerous practice.

The literature of this subject is very extensive, as may be seen from Ronald's *Catalogue of Works on Electricity*. The reader may also consult Anderson on *Lightning Conductors* (1880), and the *Report of the Lightning-Rod Conference* (1882). In the latter work will be found abstracts of many valuable papers, especially the reports on lightning-rods made to the French Academy by some of its most distinguished members, including Coulomb, Laplace, Poisson, Gay-Lussac, Fresnel, Pouillet, Cagniard, de la Tour, Regnault, &c. There will also be found hints about some of the most ludicrous devices employed by men ignorant of the laws of electrical phenomena. One of the most singular of these was the so-called "Repeller." A lightning-rod, in all respects sufficient, was wont to be capped by a piece of glass like a thick soda-water bottle, inverted upon its point. The effect of this could only have been to prevent the possibility of the silent discharge, to produce which is the proper function of the rod, and to make probable a lightning flash, just as if the rod had been terminated by a ball instead of a point. One of these dangerous monuments of ignorance was removed from a British lighthouse within the last ten years. In an Irish lighthouse, which was recently examined after suffering serious damage, it was found that the lower end of the lightning-rod was jumped into the solid rock — a truly original form of "earth!"

In 1876 Clerk Maxwell suggested to the British Association the idea (based on Faraday's experiments) of protecting a building from the effects of lightning by surrounding it with a sort of cage of rods or stout wire. Here an "earth" would not be absolutely required. The present writer had some months previously suggested the same idea in a Report to the Board of Northern Lights. It is possible, though not certain, that this form of defence might be useful against globe lightning, which undoubtedly occurs, and against which ordinary lightning-rods would probably be of little use.

These hints contain all that is yet known to be necessary to the complete solution of an important practical problem about which many treatises have been written. (P. G. T.)

LIGNUM VITÆ. See GUAIACUM.

LIGUORI, LIGUORIANISM. The name Liguorianism has been popularly given in the present century to a particular school of moral and devotional theology in the Roman Catholic Church by the controversial opponents of that school, whether themselves Roman Catholics or not. It is derived from the name of one of its principal and most influential exponents, Alfonso Maria de' Liguori, a theologian, saint, and doctor of the Roman Church. In strictness, the term is not accurate, for Liguori was in no sense the founder of the school, nor did he innovate upon, develop, or exaggerate its principles and maxims. He was simply a fair representative of the national type of piety of Italian devotees in his day; and, as a casuist, he was a diligent compiler, whose avowed design was to take a middle course between the two principal varieties of teaching in moral theology current in his own time, avoiding their extremes of severity or laxity. His own words, in the preface to his *Homos Apostolicus*, a work intended for the guidance of priests in hearing confession, explain clearly the intention of his bulkier treatise, the *Theologia Moralis*. He says: — "When compiling that work, I spent the labour of fifteen years in perusing and weighing the teaching of very many writers whom I examined, some of whom I found more lenient than is just; . . . while I found others who, strongly disliking such indulgence, fell into the other extreme of *excessivo rigour*. And this was my principal task, to select from such a mass of opinions those decisions which, on the one hand, should uphold the obedience due to the precepts of God and of the church, and on the other should not add burdens which God has not imposed, by binding every one to that perfection which, through human weakness, is morally impossible to the general body of believers." A brief glance at the names of those casuists whom he cites most frequently, as Covarruvias, Soto, Lessius, Vasquez, Bonacina, the doctors of Salamanca, Sanchez, Diana, &c., shows them to belong mainly to the hundred years between 1580 and 1680, and

<sup>1</sup> Some curious modifications of this statement are introduced when we deal with magnetizable metals, but they are unimportant in practice.

therefore to the period of Jesuit predominance in moral theology, and of the prevalence of those maxims which Pascal lashed in the *Provinciales*, many of which were soon after condemned by Pope Innocent XI. in 1679. But, as Liguori embodies also in his materials the casuistical authors of the succeeding century, who were taught some caution by those mishaps of their predecessors, his works represent the final stage of casuistry in what is accounted a purified and moderate form, and have a yet greater importance, in that they have been accorded an official approval and authorization from the highest authorities of the Roman Catholic Church, such as those of no previous casuist of the post-Reformation era can allege. They are fully sanctioned, encouraged, and recommended for general use amongst the Roman Catholic clergy, and in fact only just fall short of being actually enjoined. Consequently they themselves, and the works based on them by Scavini and Gaume, as also the kindred manual of Gury, are all but universally found in use, and it is thus easy to learn from them what is now the accredited moral theology prevalent throughout the Latin obedience. So much being premised, we may now turn to the life of Liguori himself, and thence to the analysis of the system which he expounds.

Alfonso Maria de' Liguori, son of Giuseppe de' Liguori, a Neapolitan noble, and of Anna Cavalieri de Brindes, his wife, was born at Marianella, near Naples, on September 27, 1696. He was educated chiefly at home, though he attended an Oratorian school at Naples for a time; and, as his father desired that he should rise to office in the magistracy, he was especially directed to the study of jurisprudence, both civil and canonical. He took the degree of doctor in this faculty in January 1713, being then little more than sixteen years old. He was called to the bar in due course, and obtained considerable practice, while his biographers dwell much on the high moral tone of the rules he laid down for his guidance in the conduct of professional business. The loss of an important suit in which he was engaged as counsel for a Neapolitan noble against the grand duke of Tuscany, and in which he had entirely mistaken the force of a leading document, so mortified him that, acting on a temper already disposed towards the monastic life, it induced his withdrawal from the legal profession, which he never resumed after this defeat. He soon adopted the ecclesiastical dress as a candidate for orders, which he received in December 1721, when he entered as a novice into the Congregation of Missions, being ordained priest in December 1726.

He soon became popular as a preacher and as a confessor, obtaining much influence in Naples and its vicinity. In 1732 he founded the "Congregation of the Most Holy Redeemer," usually known as Redemptorists, or, as they are often named, Liguorians, whose special object is the religious instruction of the rural poor and other uneducated classes, establishing the first house of the society, in the face of much opposition, at the little town of Scala, about 8 miles from Salerno. The headquarters were transferred somewhat later to Giorani, and in 1743 to Nocera dei Pagani, which is still the chief house. The confirmation of the rule and institute was obtained from Benedict XIV. in February 1749, and in the following year Liguori, who had previously made some minor literary ventures, published one of his most famous and popular books, *Le Glorie di Maria*, a book intended to promote the cultus of the Blessed Virgin; and in 1753 he issued his yet more celebrated *Moral Theology*, dedicating it to Pope Benedict XIV., expressly as a "via media" treatise. An Italian version of this book, somewhat abridged, recast, and adapted for the use of the clergy, was his next task; and, on this shorter treatise becoming

popular, and a demand for it arising outside of Italy, he translated it into Latin, and issued it in 1755 as the *Homo Apostolicus*.

In 1762, being then sixty-six years of age, he accepted the bishopric of Sant' Agata dei Goti, a small town in the province of Benevento, at the express desire of the pope (though he had several years before refused the archbishopric of Palermo, offered him by the king of Naples), and by a very unusual concession was permitted to retain his superiority of the Redemptorists, governing them by means of a vicar general. He worked diligently in this sphere of labour for thirteen years, busying himself with practical reforms of various kinds in his diocese, notably in trying to raise the standard of clerical life and work, while not intermitting either his literary pursuits or his efforts to promote the growth of his Redemptorist institute. In 1775, being then seventy-nine years of age, he obtained permission from Pius VI. to resign his bishopric, on the plea of enfeebled health, and retired to the Redemptorist house at Nocera dei Pagani, where he died August 1, 1787, aged nearly ninety-one. He was raised the rank of "Venerable" very speedily, being canonized by Pius VI. in 1796, was beatified by Pius VII. in 1816, canonized by Gregory XVI. in 1839, and finally declared a "Doctor of the Church" by Pius IX., March 11, 1871. He is one of the most copious of the later Roman theologians, and his productiveness extended over a period of thirty years, from the issue of his *Visits to the Blessed Sacrament* in 1717 till the appearance of no fewer than eleven treatises in 1777; but his only writings necessary to be added here to those already named are his treatises *De Usu Moderato Opinioni Probabilis*, 1754, recent and issued in 1756; *Pœnis Confessorii*, 1766, six apologies in defence of his views on probabilism and of his *Moral Theology*, in the same year, followed by three more in 1768; *Verba della Fede*, against Helvetius and the deists, 1767; *Storia della Eresia*, directed chiefly against the Jansenists and Molinists, 1772; *Dissertationi teologiche*, 1772, and *Vindice pro supremo Pontifici potestate adversus Justinum Feltrinum*, in the same year.

He was a man of naturally amiable and gentle disposition, ascetic and self-denying in his personal habits, indefatigably diligent in many forms of activity, and of more than respectable abilities, though with the emotional side of his character in greater relief than its intellectual side. He was learned, as learning was understood amongst the Italian clergy of the 18th century, though altogether lacking in critical faculty, whence he is quite untrustworthy as a controversialist, not only as habitually quoting spurious or interpolated authorities, but by adding matter of his own to amplify genuine quotations which fall short of proving his case. In estimating the nature of his moral teaching, not only have these personal characteristics to be steadily kept in mind, but also the fact that his life exactly synchronizes with that epoch of European history which was the seed time of the Revolution, and when, owing to reaction from the fervid theological controversies of the 16th and 17th centuries, a general languor, coldness, and indifference towards religious questions reigned in all parts of Western Christendom. It was Liguori's firm belief that only the most lenient and gentle treatment could win back the alienated laity; and consequently, though he professed to steer a middle course between errors of laxity and severity in moral teaching, and fully believed himself to have done so, yet in fact such a treatment was impossible to one who viewed the question as he did. For, while he regarded errors on the side of laxity as pardonable mistakes committed through excess of zeal in winning over penitents, contrariwise he looked on the stricter method of the rigorists, who upheld a loftier

morality, as not merely inexpedient, but as positively and intentionally evil, as designed to make religion odious by making it impossible, and so to prepare the way for the triumph of unbelief. He identified all teaching of the sort with Jansenism, and Jansenism, from its resistance to various pontifical decrees, seemed to him all but equivalent to atheism.

Hence the opinions of rigorist theologians find almost no place in his writings, save for the purpose of censure, since he did not regard them as authorities to be relied on; and accordingly the line he draws is not, what he probably thought it, an intermediate one between rigorism and laxity, but between a greater and a lesser degree of laxity, depending on the working of the principle known as "Probabilism." The meaning of this principle (due to the scholastic form of the Aristotelian dialectic, and thus visible in germ as early as St Thomas Aquinas, though not taking final shape till the writings of Medina, Valencia, Vasquez, and others, mainly, but not exclusively, Jesuits, at the close of the 16th century) is simply this:—when a doubt arises as to the binding force of some divine or human precept in any given case, it is permissible to abandon the opinion in favour of obedience to the law—technically known as the "safe" (*tuta*) opinion—for that which favours non-compliance, provided this laxer opinion be "probable." And by "probable" is meant any judgment or opinion based on some reasonable grounds, though with some doubt that the opposite view is perhaps the true one (Gury, *Theol. Mor.*, vol. i. n. 51). It may be probable in two chief ways,—intrinsically, because of reasons drawn from the nature of the thing itself, or extrinsically, because supported by one or more theologians of repute; and its degree of probability may vary according to a variety of conditions. Casuists are divided into six classes according to their mode of regarding probability:—(1) Rigorists, who lay down that the safer way, that of obedience to the law, is always to be followed; (2) Mitigated Rigorists, or "Tutorists," who, holding that the law is always the safer and better way, yet allow that an opinion of the highest intrinsic probability in favour of liberty may sometimes be followed; (3) Probabiliorists, who hold that the law is always to be obeyed unless an opinion clearly very probable (*probabilior*) is opposed to it; (4) Equiprobabilists, who teach that in a balance of opinions the less safe opinion may be lawfully followed, provided it be as probable, or nearly as probable, as its opposite; (5) Moderate Probabilists, according to whom it is lawful to follow the less safe and somewhat less probable opinion, provided it have some degree of real probability, even if the opposite opinion be clearly more probable; (6) Laxists, who hold that even slightly probable opinions may be followed; but, as they were condemned by Innocent XI., they no longer exist as an avowed school, but are still latent under classes 4 and 5.

On further examination, it appears that the right of judging of the *intrinsic* probability of an opinion is restricted to persons of considerable learning, and specially versed in moral theology, since they alone can know that there is not any certain argument in opposition. All other inquirers must fall back on *extrinsic* probability, that is, on what may be called "counsel's opinions." And, in forming a judgment on this basis, the following rules are laid down by F. Gury—a moderately educated person may accept as probable any opinion which he finds asserted by distinguished theologians of the present day, and may follow even a single author of repute, though teaching contrary to the commonly received view, provided he brings forward some fresh argument, and can urge reasonable pleas against former solutions; while an ignorant man may take the word of any person whom he thinks trustworthy, able, and

learned, that a particular opinion is probable (*Theol. Mor.*, vol. i. n. 54). Some classes of things are, however, excluded by Roman casuists from the operation of this principle; as, for example, all questions relating to matters of faith, in which the very highest degree of probability is not sufficient to excuse from following the safe opinion, which is that of the Roman Church. Liguori's own position is that of an equiprobabilist, and he therefore, as a rule, leans to the laxer side.

Before proceeding to illustrate the exact nature of his teaching by extracts from his works, it is desirable to ascertain what degree of authority attaches to those works in virtue of the position now accorded to him. In the first place, one of the earliest steps in the process of canonization is a strict review of every writing of the candidate proposed, whether published or unpublished. Every single proposition therein must be separately considered, and be judged on its own merits, without taking the author's probable intention into account, and if even one passage be found which fails to stand this test, as containing any moral or theological error, the process is stopped at once, unless proof be adduced that the author had in his lifetime formally and fully retracted the erroneous opinion. But a decree of the Congregation of Rites, confirmed by Pius VII. in 1803, declared that in none of the writings of Alfonso de' Liguori was anything found, meriting censure, and the testimony of Artico, bishop of Asti, and prince-bishop of the papal household, is that the examination had been unusually severe, that Liguori's system of morality had been discussed more than twenty times, and that the approval of the congregation was perfectly unanimous. Next, in the year 1831, Cardinal Rohan-Chabot, archbishop of Besançon, submitted a case to the cardinal grand penitentiary, desiring to know, whereas the teaching of Liguori's *Moral Theology* was resisted by some persons in his diocese, as too lax, dangerous to salvation, and contrary to the moral law, whether a professor of theology might safely follow and teach the opinions in that work, and further, whether a confessor should be molested for following those opinions in the confessional, solely on the ground that they had been pronounced free from censure by the apostolic see, and without having examined them independently himself. To the former of these questions an affirmative reply was given, to the latter a negative one. Thirdly, in the bull of canonization, issued by Gregory XVI. in 1839, the entire absence of error in Liguori's writings is once more asserted.

So far, no more is implied than the entire orthodoxy and moral soundness of Liguori's writings, vouched for to the ordinary Roman Catholic by the fact of his canonization. And, though the liberty is thereby taken away of directly censuring any proposition in the writings of a saint as doctrinally or morally untenable, yet there is no precise obligation to follow all things contained therein. It is still lawful to challenge the opinions of a saint, if it be done modestly and with the production of strong reasons (Bened. XIV., *De Canoniz.*, ii. 32, 12); but this liberty is very seriously abridged if the saint be also a "Doctor of the Church." For the meaning of that title is that the person who bears it is one who has not merely transmitted the teaching of the church to others, but has taught the church itself (Bened. XIV., *De Canoniz.*, iv. ii. xi. 11), and whose doctrine has consequently been generally followed and authorized by the church. The number of the doctors of the church is very small; and, in the special case of Liguori, he is not only the latest so named, but the only post-medieval casuist who has yet been canonized. Accordingly, it is not merely permissible, as heretofore, to follow his teaching, but it is now clothed with so high a degree of authority that it becomes matter of grave doubt

whether even such a modified expression of dissent from his teaching as occurs in the *Apologia* of Cardinal Newman in 1864 be now feasible without risk of censure. For the letters apostolic of Pius IX. declare that the works of Liguori may be used publicly in the same manner as the writings of other doctors of the church, such as Augustine, Gregory the Great, and Thomas Aquinas; with, however, this notable difference that, whereas the teaching of those earlier doctors is necessarily qualified and conditioned by the subsequent development of theology, and by the successive glosses which they have received, on the other hand, Liguori's recent date makes him the sole authoritative interpreter of all moral theologians earlier than himself, while no writer has yet appeared to modify authoritatively, much less to supersede, his own moral teaching.

It may seem, at first sight, that a great advantage is gained by having thus a standard text-book on morals, even if some exceptions may be taken to its rulings in certain cases, because it may be expected to check serious divergency of opinion, and to put, indirectly at least, a high ethical ideal before the body of religious teachers. This, however, can be the case only when such a text-book expressly repudiates the principle of probabilism, and so comes to be ranked amongst rigorist works. For once probabilism is conceded as part of the system, as is the case with Liguori, then every opinion not officially condemned by authority, which is set down in the text-book itself, and is fortified with the names of any casuists of repute, becomes thereby probable and sanctioned, even though it be not the one professed by Liguori himself. Thus it may freely be followed by any priest in the confessional; and, what is yet more startling, it is the common and preferable doctrine that a penitent in confession can require absolution to be given him as a right, if he claim to have followed a probable opinion as to the act involved, even though not only the opposite opinion may be the more probable in the confessor's judgment, but that of the penitent seem absolutely false, and the confessor is therefore bound *sub gravi* to absolve in such a case (*Lig., Theol. Mor., vi. 605*); nor is it necessary that the opinion which the penitent advances should really convince or satisfy his own conscience. It is enough that it stands in the books, and is citable. Accordingly, the only practical effect of such a text-book as Liguori's is to undermine all rigorist propositions, and to make tenable every lax proposition, except the very few which have been specifically condemned.

As regards Liguori himself, his usual method is to begin with taking very high ground, and to state in unexceptionable terms the moral obligation of the precept with which he is concerned, but then to evacuate it of all real force by exceptions and qualifications. That such was felt to be the case, even in the relaxed society of his own day, appears from the frequency with which, even before his death, his moral teaching was impugned in Italy and France as of dangerous consequences, and from the number of apologies he was obliged to put forward in its defence.

He lays down broad general propositions, such, for example, as that all voluntary departure from the divine rule, whether of human and natural law or of revealed law, is sin (*Theol. Mor., ii. 1, 1*); that nearly all sins against the decalogue are mortal sins (*Ibid., ii. 52, 2*); that all sins, whether mortal or venial, deserve punishment (*Ibid., ii. 51, 1, 2*); and, specifically, that all lying and falsehood is a breach of one precept of the decalogue (*Ibid., vi. 1, proem.*), and all theft and dishonesty a breach of another (*Ibid., iv. 518*); but the favourable impression which such unimpeachable rulings produce is not maintained on further inquiry.

In the first place, he lays down that, to make any act sinful, three conditions must be fulfilled:—(1) it must be

done with consent of the will; (2) it must be free, that is, it must be in the power of the will to do it or leave it undone; (3) there must be intellectual consciousness (*advertentia*) of its evil nature. These look specious enough, and against the first no objection can be raised. But Liguori then alleges that violent gusts of passion or desire, which disturb the reason, and take away liberty of action, sometimes excuse from sin (*Ibid., ii. 1, 2*). He is not speaking of actual insanity, which is not under consideration; and he adds that evil acts done by a drunken person are either not sinful at all, or are at most venial sins (*Ibid., ii. 1, 4*), because the effect cannot be more sinful than the cause. And as to the degree of advertence necessary as a condition of sin, he first mentions the stricter view, that actual and immediate attention to the nature of the act is not required, but that a virtual knowledge of its character suffices, by which a man might reasonably be expected to recognize it, since otherwise all evil doers who are blinded by their passions, or by a long course of malpractices, may go on taking no notice, and continue to commit sins with moral impunity. He then states the laxer and commoner view, that some direct advertence of the sinful nature of the act is necessary to constitute sin in doing it, and proceeds to reconcile these two opinions by ruling that voluntary ignorance, whether due to conscious neglect, to deliberate following of passion, to a course of evil habit, or to omission of the degree of consideration which the act demands, does not excuse from sin; but that all other forms of it do acquit the offender. The obscurity inseparable from some of these qualifications complicates a sufficiently simple matter, and in any case the doubter is at liberty to fall back on the laxer opinion. But there is one exception;—unbelievers and heretics cannot plead ignorance as their excuse. All their errors, of whatever kind, are imputed to them as sin (*Ibid., ii. 1, 1*). A farther difficulty is created by the distinction made between mortal and venial sins, and by the inferences drawn from this distinction. "A mortal sin is that which, by reason of its gravity, dissolves grace and friendship with God, and merits eternal punishment. It is called mortal, because it takes away the principle of spiritual life, that is, habitual grace, and brings death on the soul. A venial sin is that which, by reason of its slightness, does not take away grace and friendship, though it abates the warmth of charity, and deserves temporal punishment. It is called venial, because, without damage to the principle of spiritual life, that is, grace, it brings on the soul an easily curable weakness, and easily obtains pardon" (*Ibid., ii. 51*). This seems at first merely a recognition of the broad practical distinction between serious and trifling offences acknowledged by every sound ethical thinker and by every civilized penal code. But its consequences go much further, for in the Roman system of casuistry the aim is as a rule to attenuate mortal sins into venial ones; while these latter are regarded as of such little moment as scarcely to deserve the very name of sin. This appears from the fact that, whereas the canon (xxi.) *Omnis utriusque sexus fidelis* of the council of Lateran (1215), which first made private confession compulsory, enjoins the confession of all one's sins at least yearly, on the other hand, the council of Trent (Sess. xiv. c. 5) lays down that only mortal sins need be so disclosed, while venial sins, though they may be named in confession, according to the practice of devout persons, can be passed over in silence without any fault. And Liguori gives his own sanction to the proposition that a Christian does not sin gravely who proposes to commit *every one* of the venial sins (*Theol. Mor., v. 1, 12*). Such being the light estimate of these sins, it might be fairly supposed that great care would be taken to mark them off so clearly from mortal sins that even the least instructed conscience could not

confuse them with each other. But every sin which, considered in itself, is mortal, becomes venial if any one of these three conditions be absent:—full advertence and deliberation; entire consent; for the most part, gravity of the subject matter. Insufficient deliberation may be known in three ways:—imperfect consciousness of the sinfulness of the act, as if one were half asleep; subsequent regret, and a conviction that you would not have done the act had you fully apprehended it; such disturbance, through passion, alarm, or distraction, as to confuse the sense of what you were doing. Imperfect consent is established by the presence of a doubt in any one's mind whether he did really consent; by the habitual disposition being that of regarding mortal sin as a worse evil than death; by consciousness of having proceeded very timidly and hesitatingly in the action; by being half asleep, so as to be only doubtfully conscious, and being of opinion that the act would not have been done in case of full possession of the senses. And gravity of the subject matter is to be decided, not merely on the merits of the thing in itself, but in its relation to the end proposed by the agent. It makes but little for this if it is trifling; if much, then it becomes serious (*Theol. Mor.*, ii. 51, 55, 56).

It is obvious that each of these subdivided qualifications admits of indefinite hair-splitting, and so that the security apparently provided by the general distinction between mortal and venial sins is elusive. It is true that there are also cases which will raise a venial sin to the rank of mortal; but the ascending process is more uncertain and difficult than the descending one. A venial sin, committed deliberately as a stepping-stone to a mortal sin, is to be judged in respect of this its object, and so becomes mortal. A venial sin, so passionately clung to as to make its voluntary ready to commit a mortal sin rather than forego its indulgence, also becomes mortal. But in neither of these cases is it necessary to regard the venial sin, only the mortal to which it has led up. The third mode of a venial sin becoming mortal is when it is committed with the formal and express purpose of disobedience to a superior, or to precept, just because it is a precept. And in this case alone, because of the supreme place given to obedience in the Roman system, wherein it is not only the first and highest of virtues, but practically almost the only one insisted on for all, there is no manner of withdrawal from the category of mortal sins (*Theol. Mor.*, ii. 59, 60, 61).

So much, then, for the general principles on which Liguori's system is based. In the next part of his treatise, he proceeds to exhibit three practical applications, each in regard to his own statements, and also to certain suppositions of others. First, which, therefore, not accepting them for his, he yet cannot without censure in his work, thereby saving them from the force and sanction of probability. It will amplify the foregoing, but not, though not exclusively, to the full length of his book and plan.

Both of the cases of the first, second, and third of grave character, and in regard to the former he cites, amongst other authorities, the condemnation of the words of Pope Innocent III.: "Not contented and urged to be heard to speak falsely." He adds that persons who are being lawfully questioned by such as have a right to interrogate, such as judges, or a priest in the confessional, are bound to tell the truth, and that they know of the matter inquired into. The second case is questioned by such as have no right to interrogate, but are questioned irregularly by lawful authority, and not by the confessor, and their knowledge, and may at a side and not a side, answering by any lawful means, such means however, as a false statement, or an answer made with mental reservation, and the words actually spoken false, this latter mode of evasion, long been formally condemned by Innocent XI. in 1679, there is a great probability by the authority of the immediately preceding period. The second is a double-edged sword, but its apparent force is easily due to the fact of its ambiguity.

In the first place, then, we have an ambiguity or equivocation in mental reservation, which has three varieties of equivocation: (1) that of a word having two or more different senses, as *color* in Latin may mean "with" and "with" to which may be added the frequent English habit of using a word having the same sound, as *car* and *here*; (2) a sentence having two main meanings, as "This

book is Peter's," which may signify his ownership or his authorship; (3) that of words having two senses, one more common than the other, or one literal and the other metaphorical. The example he gives of this last form is the phrase "I say No," uttered by a person who wishes to conceal something as to which he is questioned. The words seem to his hearer to denote express denial of the fact; the meaning in which he uses them is merely "I utter the word 'No,'" this sentence being complete in itself. "It is certain," adds Liguori, "and the common opinion of all, that it is lawful for a just cause to use equivocation in the manners described, and to confirm it with an oath. . . . And the reason is because we do not then deceive our neighbour, but for a just cause permit him to deceive himself; and besides, we are not bound, if there be a just cause, to speak so that others may understand. And any honest object for retaining any good things that are useful to our body or spirit may be a just cause" (*Theol. Mor.*, iv. 151).

But suppose that it is impossible to allege a just cause, is it then mortal sin to swear with such equivocation? Some of the stricter casuists say so, but Liguori sides with the laxists, and declares it merely venial, except in a court of law or in formal contracts,—alleging that, save in these two cases, any reasonable cause, such as desire to be quit of troublesome and irregular questioning, is sufficient to mitigate the sin. He adds, however, two cautions—that a more serious cause is required to justify equivocation with an oath than without one, and that,

employed as a greater occasion for mistake, a graver cause is required for their proper use, a qualification instantly modified by the next clause, which lays down that, when words which are in themselves equivocal, having two equally valid meanings, are used, then they give little or no cause for error, and may be used on the very highest grounds.

Next, as to mental reservation, or "restriction," which is the technical name, this was expressly condemned in three propositions by Innocent XI., forbidding it in all cases. According to the analogy of all prohibitory laws, this general prohibition of the genus should include prohibition of all the species also. But the casuists, unable to oppose direct resistance to the papal decrees, have turned its flank by inventing a new distinction which was not known in 1679. They have now divided mental restriction into two main heads, the first of which, absolute or "pure" mental restriction (by which is meant such reservation as cannot possibly be observed by the hearers, or conjectured from the attendant circumstances), is always illicit, whether with or without an oath. But "non-pure" mental restriction (that is, such as may possibly be observed and inferred from attending circumstances, such as an inclination to whisper, or a qualifying gesture) does not, they allege, fall under the ban of Innocent XI., and is always lawful for a just cause. The reason of this opinion is that, if it were not permissible to use non-pure mental restriction, there would be no lawful means of concealing a secret, which one could not disclose without loss or inconvenience, which would be as hurtful as lying to human intercourse, therefore the condemnation passed by the pope on mental restriction is rightly to be understood of a restriction taken absolutely truly, for that alone can be called true mental restriction and takes place in the mind alone, and so remains hidden, and no wise be recognized from external circumstances" (*Theol.*, iv. 152). And the following illustrations are supplied. (1)

One may affirm with an oath that he is ignorant of a crime which he has heard in confession, secretly meaning thereby that he knew of it as a mere man, though not as a minister of religion.

An accused or a witness, if irregularly questioned by the judge, may swear that he knows nothing of a crime which he in fact knows of, understanding thereby that he does not know what is to be legally bound to answer or depose concerning it. This ruling proposition is apparently corrected by the warning that, on the interrogation of the judge is in due form, then the person questioned is bound to obedience, and barred from all equivocation. If this safeguard is at once fatally weakened by the further proposition that, if the act be not a crime in the witness's opinion, he need not disclose it, and that if the crime be altogether hidden, where only the criminal himself and the witness know the fact, the witness is not merely permitted, but is actually bound, to that the accused did not commit it. And the accused is equally free to do so, unless there be already "half-full" proof against him, or, in the absence of such a degree of presumption, the judge has a legitimate right to question him as to his guilt. Those who have deceived the court by such sworn equivocation are, Liguori rules, entitled to absolution without the declaration of the truth being imposed as a condition.<sup>1</sup> (3) A needy man, who has made

<sup>1</sup> Akin to this teaching is the maxim laid down in another place, that it is lawful to procure the giving of perjured evidence, "if you have a great interest in employing perjury to expose the fraud of another person in order to obtain your own rights" (*Theol. Mor.*, iii. 3, 77), with which may be coupled the permission for suitors to offer and for judges to take bribes for expediting causes, so long as the bribing is not expressly for delivering false judgment (*Ibid.*, v. 196, 212).

away, for his maintenance, with property due to his creditors, may affirm to the judge that he has nothing. (4) A witness asked by the judge whether he has had any conversation with the accused may deny it, meaning that he has not talked with him so as to co-operate in the crime. (5) An adulteress, questioned by her husband as to her guilt, may deny it in any of these four ways: (a) that she has not broken the marriage-tie, because it is not voided by adultery; (b) if she have gone to confession, she may say that she is innocent of the crime, because it has been remitted in confession; (c) that she has not committed adultery, using the word in its frequent Biblical sense of "idolatry"; (d) that she has not committed it so as to be bound to tell him of it (*Theol. Mor.*, iv. 153-162).

Promises are no safer than assertions under this code. As usual with Liguori, a broad statement of their binding character is prefixed to the qualifications which leave nothing but the outer shell remaining. For we are told (a) that "the whole obligation is commonly understood as depending on the intentions of the promiser, and not binding unless that be confirmed with an oath or a formal document, in the absence of which it may be considered a mistake or a jest"; and (b) that "it is certain that every promise, even an accepted one, does not bind, if after the date of the promise it becomes impossible, or very hurtful, or unlawful, or useless, and generally speaking, when there has been a serious change of circumstances, which, if foreseen, would have prevented the promise; such a promise is always presumed to have been made under some such tacit condition" (*Theol. Mor.*, iv. 720).

Theft is treated in a very similar fashion. A broad general rule is laid down as to its sinfulness, and this is at once traversed by the following doctrine: "It is certain that a man who is in extreme necessity may purloin other people's goods, enough to relieve himself from such necessity." So the doctors in common say, agreeing with St Thomas. "Extreme necessity is defined as meaning risk of loss of life, or of some limb or other important body member, peril of perpetual captivity, or of any serious disease or discredit. And Liguori, contradicting the stricter casuists, includes under the same heading the case of a man of rank reduced to work or to beg, who may then lawfully steal to maintain himself. Then the case is put whether a poor man in extreme need is free to steal before asking. One rigorist lays down that it is a mortal sin to do so, because no man can be held to be in extreme need who can get what he wants by asking. But the laxer casuists rule that, though he is bound to ask first, he sins only venially by omitting to do so; and Liguori solves the difficulty by saying that the robber sins mortally if what he takes is not absolutely necessary to relieve his want, but that, if he does so need it that the owner, if aware of the fact, would be bound by the laws of charity to give it him, then he does not sin even venially by stealing it, because he has in that case an absolute right to take it (*Theol. Mor.*, iv. 520).

Some of these rulings are contrived so as to evade the condemnation passed by Innocent XI. on the proposition that "it is allowable to steal, not only in extreme necessity, but also in grave necessity." But a more direct conflict with the papal ruling appears in respect of another censured proposition, that "no master who employs servants may secretly pilfer from their employer, to compensate themselves for their work, which they account as of more value than they receive." This is explicit enough, but it is at once evaded by the casuists, who allege that the rule holds good only in the case of a servant who has of his free will contracted to accept a low salary, as he thereby bars himself from compensation, but if he has made a bargain under any sort of constraint, as, for instance, being in great poverty, and thus glad to take any situation, he is at liberty to steal to the amount of what he considers his just additional wage. Some casuists do, indeed, question the servant's right to be judge and assessor in his own cause, but the point is ruled practically in his favour (*Theol. Mor.*, iv. 523, 524). Again, servants may purloin such eatables and drinkables as are not locked up, provided they do so for their own consumption, and not to sell out of doors, and so long as each such theft is simply trifling (*Ibid.*, iv. 54). Even when restitution is enjoined, there is a notable provision in favour of the thief. If he is uncertain who it is he has robbed, he is to make restitution in one or other of certain ways, one of which is that if he be poor he may apply the proceeds of the theft to himself or to his family (*Præc. Confess.*, ii. 44).

In addition to these glosses on the decalogue, there is one element of doubtfulness introduced into nearly all questions of theft, which is, as to the "gravity of matter," constituting the offence mortal or venial according to the degree of this factor, and a comparison of the various places where Liguori employs the term "gravi materie" shows that in all cases where numerical expression apply he means *quantity*. Accordingly, he, in common with many other casuists, constructs a sliding tariff of guilt, depending, as a rule, on the amount stolen (*Theol. Mor.*, iv. 526-528).

A few brief citations from other decisions will show that the same principles applied to questions of lying and theft extend to the remaining forms of sin. (1) A man of high position may lawfully kill any one who attempts to slap his face, if there be no other way of warding off the insult (*Theol. Mor.* iv. 38). (2) He who kills

A, meaning to kill B, is not bound to make compensation, because the homicide is casual and inadvertent as regards A; and similarly if a man burns down the house of his friend, meaning to burn that of an enemy (*Ibid.*, iv. 628, 629). (3) Though we are bound to love our enemies, we are not bound to salute them, to speak to them, to visit them if sick, to comfort them in any trouble, to receive them into our house, or to hold any kind of familiar intercourse with them (*Ibid.*, v. 3, 28). (4) A servant may help his master, by lifting him on his shoulder, or by providing him with a holder, to enter a house, even forcibly, for immoral purposes; for the act is innocent and honourable in itself, may, even as an act of charity or good-will, and the servant is not responsible for the subsequent conduct of his master (*Ibid.*, iii. 3, 66).

For all purposes of definition, which is at the base of all theoretical method, and which imply the substitution of an external authority for the notions of conscience, is now in absolute possession throughout the Latin obedience, having finally conquered the resistance it has encountered at intervals since its first formulation as a working theory. Although it owes its chief development to the Jesuits, yet some of its ablest opponents were members of that company, such as Coratelli, Bellini, Gherard, and even two of the general, Muzio Vitellio and Don Giovanni de' Medici, while the Society and the Dominicans were so engaged in frequent controversy against its upholders, and in censuring the teaching of several of Liguori's favourite authorities, such as Lessius, Escobar, Tandelmont, Bonny, Viva, Bagnolini, and Bona.

3301, 3302, 3303, 3304, 3305, 3306, 3307, 3308, 3309, 3310, 3311, 3312, 3313, 3314, 3315, 3316, 3317, 3318, 3319, 3320, 3321, 3322, 3323, 3324, 3325, 3326, 3327, 3328, 3329, 3330, 3331, 3332, 3333, 3334, 3335, 3336, 3337, 3338, 3339, 3340, 3341, 3342, 3343, 3344, 3345, 3346, 3347, 3348, 3349, 3350, 3351, 3352, 3353, 3354, 3355, 3356, 3357, 3358, 3359, 3360, 3361, 3362, 3363, 3364, 3365, 3366, 3367, 3368, 3369, 3370, 3371, 3372, 3373, 3374, 3375, 3376, 3377, 3378, 3379, 3380, 3381, 3382, 3383, 3384, 3385, 3386, 3387, 3388, 3389, 3390, 3391, 3392, 3393, 3394, 3395, 3396, 3397, 3398, 3399, 3400, 3401, 3402, 3403, 3404, 3405, 3406, 3407, 3408, 3409, 3410, 3411, 3412, 3413, 3414, 3415, 3416, 3417, 3418, 3419, 3420, 3421, 3422, 3423, 3424, 3425, 3426, 3427, 3428, 3429, 3430, 3431, 3432, 3433, 3434, 3435, 3436, 3437, 3438, 3439, 3440, 3441, 3442, 3443, 3444, 3445, 3446, 3447, 3448, 3449, 3450, 3451, 3452, 3453, 3454, 3455, 3456, 3457, 3458, 3459, 3460, 3461, 3462, 3463, 3464, 3465, 3466, 3467, 3468, 3469, 3470, 3471, 3472, 3473, 3474, 3475, 3476, 3477, 3478, 3479, 3480, 3481, 3482, 3483, 3484, 3485, 348

rugged territory with much industry, and opposing a stubborn resistance to the efforts of the Romans to reduce them to subjection. They first came in contact with the Roman arms in 235 B.C., but it was not till after the Second Punic War—in which the Ligurians had openly espoused the cause of Hannibal—that a serious struggle began, which, commencing in 200 B.C., was continued with little intermission for more than eighty years. While the Roman generals in the East were overthrowing, with comparative ease, the powerful monarchies of Macedonia and Syria, one of the consuls was generally engaged in inglorious hostilities with the hardy mountaineers of the Ligurian Apennines. Even after these were reduced to subjection, the tribes which held the still more rugged fastnesses of the Maritime Alps long maintained their independence, and it was not till the reign of Augustus that they were finally subdued. The construction by that monarch of a Roman highway along the coast, which followed almost exactly the same line as the modern road of the Corniche, marked the period of their complete subjection.

The physical geography of Liguria has been already described in the article of ITALY. All the rivers which take their rise on the northern slope of the mountains ultimately discharge their waters into the Po; of these by much the most considerable is the Tanaro, which receives the tributary streams of the Stura and the Bormida, while to the east of it flow the Scrivia and the Trebia, celebrated by the victory of Hannibal over the Romans. This last stream, according to the division of Augustus, formed the boundary between Liguria and Gaul south of the Po. The streams which flow from the Apennines southward to the sea are for the most part inconsiderable, and mere mountain torrents. But the Magra, which forms the limits of the province on the east, is an important stream, and brings with it the waters of its tributary, the Boactes or Vara. On the west also the Var is a river of considerable magnitude, which forms a natural boundary on this side between Liguria and Gaul, as it long constituted their political limit. The Rutuba or Roya, a little farther east, is also a considerable river, descending through a deep mountain valley from the Col di Tenda.

The principal Ligurian tribes were (1) the Apuani, inhabiting the valley of the Magra, including the district known in modern times as the Lunigiana; (2) the Friniates, on the northern slope of the Apennines towards Modena; (3) the Briniates, in the valley of the Vara; (4) the Genuates, around Genoa; (5) the Veturi, immediately west of the preceding; (6) the Ingauni, whose capital was Albium Ingaunum, still called Albenga; (7) the Intemelii, whose chief city still retains the name of Vintimiglia; and (8) the Veditantii, extending thence to the Var. North of the Apennines the most important tribes were the Vagienni, who held the whole mountain tract from the Monte Viso and the sources of the Po to the Tanaro; and the Statielli, east of them, whose chief town was Aquæ Statiellæ or Acqui.

The chief city on the Ligurian sea-coast was, in ancient as in modern times, that of Genoa, which combined an excellent natural port with a central position, and easy communications with the interior. West of it, along the coast, were Vada Sabbata (Vado, near Savona), Albium Ingaunum (Albenga), Albium Intemelium (Vintimiglia), the Portus Urculis Monæci (Monaco), and Nicæa (Nice), which was founded by a colony from Massilia. In its immediate vicinity was the Roman town of Cemenelium (Cimiez). On the northern slope of the Apennines were several considerable towns, almost all of them of Roman origin. The chief of these were Augusta Vagiennorum (Bene), Alba Pompeia, Asta, Aquæ Statiellæ, Dertona (Tortona), and Iria (Voghera), but none of them attained

to anything like the same prosperity and importance as the great cities of Cisalpine Gaul. The towns on the eastern Riviera, between Genoa and the Gulf of Spezia, were inconsiderable places; and even on the shores of that gulf, forming the magnificent port called the Portus Lunæ, there was never any town of importance, Luna itself being some distance inland, and within the confines of Etruria. (E. H. R.)

LILAC, *Syringa vulgaris*, L., belongs to the olive family, *Oleaceæ*. The common lilac is said to have come from Persia in the 16th century, but according to Heuffel it is indigenous in Hungary, the borders of Moldavia, &c. (De Candolle, *Prod.*, viii. p. 282). Two kinds of *Syringa*, viz., *alba* and *cærulea*, are figured and described in Gerard's *Herball* (1597), which he calls the white and the blue pipe privets. The former is the common privet, *Ligustrum vulgare*, L., which, and the ash tree, *Fraxinus excelsior*, L., are the only members of the family native in Great Britain. The latter is the lilac, as both figure and description agree accurately with it. It was carried by the European colonists to North-East America, and is still grown in gardens of the Northern and Middle States. There are several varieties of lilac, e.g., "Dr Lindley," which bears large clusters of reddish lilac flowers, *alba*, *violacea*, *rubra insignis*, and *rosea grandiflora*. *S. dubia*, Pers., or *chinensis*, Willd., the Siberian lilac, is a closely allied species, if it be really distinct. The variety *Rothomogensis*, Mirb., or *Lilas Varin* of the French, probably belongs to this species. Of other species, there is *S. Josikæa*, Jack., from Transylvania, with scentless bluish-purple flowers, *S. Emodi*, Wall., a native of the mountains of India, and *S. persica*, L., the Persian lilac, rarely exceeding 4 or 5 feet, the flowers of which vary from rosy carmine to white.

LILBURNE, JOHN (1618–1657), an English sectary and prolific pamphleteer, was the younger son of a gentleman of good family in the county of Durham, and was born in 1618. At the age of twelve he was apprenticed to a clothier in London, but he appears to have paid only slight attention to business, and to have early addicted himself to the "contention, novelties, opposition of government, and violent and bitter expressions" for which he afterwards became so conspicuous as to provoke the saying of Marten that, "if the world was emptied of all but John Lilburn, Lilburn would quarrel with John, and John with Lilburn." He appears at one time to have been law-clerk to Prynne. In February 1638, for the part he had taken in importing and circulating the *Merry Litany* and other publications of Bastwick and Prynne, offensive to the bishops, he was sentenced to be publicly whipped from the Fleet prison to Palace Yard, Westminster, there to stand for two hours in the pillory, and afterwards to be kept in jail until a fine of £500 had been paid. Though gagged at the pillory, and confined in prison, he was not the man to give up his opinions or forego the pleasure of expressing them, and in the following year he did not improve his prospects of a speedy release by the kind of literary activity to which he devoted his enforced leisure.<sup>1</sup> In point of fact he did not regain his liberty until November 7, 1640, when one of the earliest recorded speeches of Oliver

<sup>1</sup> *Come out of Her, My People: or An Answer to the Questions of a Gentleman, a professor in the Anti-Christian Church of England, about Hearing the public Ministers; where it is largely discussed, and proved to be unlawful. Also a Just Apology for the way of Total Separation, commonly but falsely called "Brownism"; that it is the truth of God though lightly esteemed in the eyes of the world. With a challenge to dispute them publicly before King and Council, to prove whatsoever I have said at the pillory against them: viz., that the willing of them is jure Diaboli, even from the Devil himself. By me John Lilburne, close prisoner in the Fleet for the cause of Christ. Printed in the year of hope of England's Purgation and the Prelates' Dissolution, 1639.*

Cromwell was made in support of his petition to the House of Commons. In 1641 he received an indemnity of £3000. He now entered the army, and in 1642 was taken prisoner at Brentford and tried for his life; sentence would no doubt have been executed had not the parliament by threatening reprisals forced his exchange. He soon rose to the rank of lieutenant-colonel, but in April 1645, having become dissatisfied with the general conduct of affairs, and especially with the predominance of Presbyterianism, he resigned his commission, presenting at the same time to the Commons a petition for considerable arrears of pay. His violent language in Westminster Hall about the speaker and other public men led in the following July to his arrest and committal to Newgate, whence he was discharged, however, without trial, by order of the House, in October. In January 1647 he was again committed to the Tower for accusations which he had brought against Cromwell, but was again set at liberty in time to become a disappointed spectator of the failure of the levelling or ultrademocratic party in the army at the Ware rendezvous in the following December. The scene produced a deep impression on his mind, and in February 1649 he along with other petitioners presented to the House of Commons a paper entitled *The Serious Apprehensions of a part of the People on behalf of the Commonwealth*, which he followed up with a pamphlet, *England's New Chains Discovered* (March 1, 1649), criticizing Ireton, and another exposing the conduct of Cromwell, Ireton, and other leaders of the army since June 1647 (*The Hunting of the Foxes from Newmarket and Triploe Heath to Whitehall by Five Small Beagles*, the "beagles" being Lilburne, Overton, Walwyn, Prince, and another). Finally, the *Second Part of England's New Chains Discovered*, a violent outburst against "the dominion of a council of state, and a constitution of a new and unexperienced nature," became the subject of discussion in the House, and led anew to the imprisonment of its author in the Tower on April 11. His trial in the following October, on a charge of seditious and scandalous practices against the state, resulted in his unanimous acquittal, followed by his release in November. In January 1652, for printing and publishing a petition against Sir Arthur Haslrig and the Haberdasher's Hall for what he conceived to have been an injury done to his uncle George Lilburne in 1649, he was sentenced to pay fines amounting to £7000, and moreover to be banished the Commonwealth, with prohibition of return under the pain of death. In June 1653 he nevertheless came back from the Low Countries, where he had busied himself during the interval in pamphleteering and such other agitation as was possible, and was immediately arrested; the trial, which was protracted from July 13 to August 20, indeed issued in his acquittal, to the great joy of London, but it was nevertheless thought proper to keep him in captivity for "the peace of the nation." He was detained successively in the Tower, in a castle at Jersey, and in Dover Castle. At Dover he came under Quaker influence, and signified his readiness at last to be done with "carnal sword fightings and fleshly bustlings and contests"; and in 1656, on giving security for his good behaviour, he was set free. He now settled at Eltham in Kent, frequently preaching at Quaker meetings in the place and neighbourhood during the brief remainder of his troubled life. He died on August 29, 1657.

See Masson, *Life of Milton*, who refers (iv. 120) also to Walker (*History of Independency*, ii. 247), Godwin (*Commonwealth*, iii. 163-177), and Bisset (*Omitted Chapters of the History of England*, 191-251), and adds, "Mr Bisset relates Lilburne's trial (in 1649) at length, with copious extracts, and makes John more of a hero than Godwin does, though Godwin is not unfavourable. On the whole, I like him myself, and am glad that he is in the history of England, but think he was an ass."

LILLE, capital of the department of Nord, France, and the ancient capital of Flanders, is situated about 155 miles by rail north of Paris, and at an elevation of 75 feet, in a low plain on the Deule, which flows to the Scheldt by the Lys. It is the chief fortress of the north of France, and headquarters of the first army corps, and is defended by a rampart and by a pentagonal citadel situated to the west of the town beside the Deule. The water of the river fills the moat, and the environs of the citadel can be laid under water. Prior to 1858 the town occupied an elliptical area of about 2500 yards by 1300, with the church of Notre Dame de la Treille in the centre, but the ramparts on the

south side have since been demolished and the ditches filled up, their place being now occupied by the great Boulevard de la Liberté, which extends in a straight line from the goods station of the railway to the citadel. The new enceinte is much more extensive, and encloses the old communes of Es-quermes, Wazemmes, and Moulins Lille, the area of the town being thus more than doubled; in the new quarters fine boulevards and handsome squares, such as that De la République, have been laid out in pleasant contrast to the sombre and dirty aspect of the old town. The district of St André to the north, the only elegant part of the old town, is the residence of the Lille aristocracy.

At the demolition of the old fortifications, the Paris gate, a triumphal arch erected in 1682 in honour of Louis XIV., after the conquest of Flanders, was preserved, as also the Ghent and Roubaix gates, which date from the time of the Spanish domination, and are built in the Renaissance style, with bricks of different colours. The present rampart is pierced by eleven gates, besides a special gate for the railway, and two water gates for the canal of the Deule. The goods station has also its special outlet, and a line from it, after making the round of the new quarters, passes within the enceinte to the quays of the river. Crossing the bridges which span the different arms of the Deule, we reach the citadel, the glacis of which,

planted with trees, form a public walk. Within the citadel are extensive barracks and a considerable arsenal. The church of Notre Dame de la Treille, in the style of the 13th century, which has been in process of building since 1855, occupies the site of the old Château du Buc, the original nucleus of the city. The town-house, on the site of the old palace of the duke of Burgundy, Philip the Good, was built in 1816. The exchange, which dates from the period of the Spanish domination, is in an original style. It is surmounted by a graceful campanile, and contains a statue of Napoleon I., made from cannon taken at Austerlitz. In the middle of the great square stands a column, erected in 1818, commemorating the defence of the town in 1792. There are several large hospitals, faculties of medicine and of science, a Catholic institute, comprising the five faculties of theology, letters, law, science, and medicine, an academy of music affiliated to the Conservatoire at Paris, several learned societies, and a large number of various kinds of schools. The picture gallery, with upwards of eight hundred works, is one of the richest in the provinces, and the Wicar museum contains a unique collection of original designs of the great Italian masters. Lille possesses also an ethnographical museum (Musée Moillet), as well as museums of archaeology, numismatics, the industrial arts, and natural history. The communal library is also worthy of mention; it includes numerous MSS., and particularly a valuable *Exemplar* of the 12th or 13th century. On the front of the building where the departmental archives are kept are to be seen medallions of all the sovereigns who have successively possessed Lille from Baldwin of the Iron Arm to Louis XIV. Lille, which is pre-eminently a manufacturing and commercial town, enjoys exceptional advantages as regards means of transit. The lower Deule is canalized to its junction with the Lys, and there is continuous water communication with the Scheldt in Belgium, and with Paris by way of Douai and St Quentin. The town is at the same time an important railway junction, and is also provided with tramways.

The principal industry is flax-spinning, in which thirty-five mills, with 190,000 spindles, give employment to 14,000 persons (of whom 9000 are females), the annual turnover being £1,800,000. Forty thread mills employ 2000 persons, and produce third to the annual value of £210,000. Fifteen factories, with 1000 operatives, produce woollen goods worth from £120,000 to £160,000 per annum; 5000 persons are engaged in cotton-spinning (115,000 spindles), to the amount of £500,000. There are besides eighty factories in which damasks, tickings, and the usual staples of the linen trade are manufactured; quilt and pillow cases occupy from 6000 to 7000 persons, and 1000 are employed in producing the fabric one of which the smock frocks of the peasantry are made. Connected with these industries are dye-works, bleach-works, and establishments for the production of candles, paper, and spinning and carding machines; and there are also a considerable number of sugar-works, breweries, and oil-works. The cultivation of hemp in Lille gives employment to 1200 persons. The total population of Lille in 1876 was 162,775.

Lille was first mentioned in the time of Count Baldwin IV., about 1000, as a small village. The little town which had arisen around the castle of the Counts of Flanders, at the end of the 12th century, Lille, which had been a free city, obtained communal privileges. In 1212, the town was destroyed by the English. In 1212, it was rebuilt by Joanna of Castile, and in 1213, it was again destroyed by Philip the Fair in 1215. After the battle of Marston, and the Flemings against the king of France, it was destroyed. In 1412. In 1369 Charles V. gave it to Louis de Blois, who then married his rights to his daughter

Margaret, wife of Philip the Bold, duke of Burgundy. Under the Burgundian rule Lille enjoyed great prosperity; its merchants were at the head of the London Hansa. Philip the Good made it his residence, and within its walls held the first chapters of the order of the Golden Fleece. With the rest of Flanders it passed from the dukes of Burgundy to Austria, and then to Spain. After the death of the Philip IV. of Spain, Louis XIV. reclaimed the territory, and besieged Lille in 1667. He forced it to capitulate, but preserved all its laws, customs, privileges, freedoms, and liberties. In 1708, after an heroic resistance, it surrendered to Prince Eugene and the duke of Marlborough. The treaty of Utrecht restored it to France. In 1792 the Austrians bombarded it for nine days and nights without intermission, but had ultimately to raise the siege. (G. ME.)

**LILLEBONNE**, capital of a canton in the department of Seine-Inférieure, France, 131 miles west-north-west by rail from Paris, and 20 miles due east from Havre, is a pretty little town, picturesquely built at the foot of wooded hills, in the valley of the Bolbec, which falls into the Seine 3 miles lower, at Port Jérôme. The principal industries are cotton-spinning and the manufacture of calico. The population in 1876 was 5400.

Lillebonne was the capital of the Caletes, or inhabitants of the Pays de Caux, in the time of Caesar, by whom it was destroyed. It was afterwards rebuilt by Augustus, who called it Juliobona after his daughter; and before it was again ruined by the barbarian invasions it had become a very important centre, whence Roman roads branched out in all directions. Some forty years ago the remains of ancient baths and of a theatre capable of containing 3000 persons were brought to light. Statues, tombstones, all sorts of articles in iron, bronze, ivory, marble, stone, glass, &c., have been found in the course of excavation, and deposited, for the most part, in the museum at Rouen. The most beautiful object yet discovered is a large mosaic found in 1870 (some 28 feet by 21). In the Middle Ages the fortifications of the town were constructed out of the materials supplied by the theatre. William of Normandy built at Lillebonne a castle whence he dates several charters. It is now a town within a charming park. The 13th century donjon, with walls over 12 feet in thickness, is in admirable preservation. The church of Notre Dame, of the 16th century, had a fine porch, formerly adorned with rich sculptures, which have mostly disappeared. The graceful tower is about 180 feet high.

**LILLY, WILLIAM** (1602–1681), an astrologer somewhat famous in his day, was born in 1602, at Diseworth in Leicestershire, his family having been settled as yeomen in the place for “many ages.” He received a tolerably good classical education at the school of Ashby-de-la-Zouche, but he naively tells us what may perhaps have some significance in reference to his after career, that his master “never taught logic.” In his eighteenth year, in consequence of his father having fallen into great poverty, he went to London, and was employed in a sort of menial situation in attendance on an old citizen and his wife, with whom he so managed to ingratiate himself that his master, at his death in 1627, left him an annuity of £20; and, Lilly having soon afterwards married the widow, she, dying in 1633, left him property to the value of about £1000. Having now a good deal of leisure on his hands, he began to dabble in astrology, reading all the books on the subject he could fall in with, and occasionally trying his hand at unravelling mysteries by means of his art. The years 1612 and 1613 were devoted to a careful revision of all his previous reading, and in particular having lighted on Valentine Naibod's *Commentary on Alchabitius*, he “seriously studied him and found him to be the profoundest author he ever met with.” Him he “traversed over day and night,” and so “advanced his judgment and knowledge” to the utmost height he ever arrived at. He characterizes him as “a most rational author and the sharpest expositor of Ptolemy that hath yet appeared.” About the same time he tells us that he “did carefully take notice of every grand action betwixt king and parliament, and did first then incline to believe that as all sub-lunary affairs depend on superior causes, so there was a possibility of discovering them by the configurations of the superior bodies.” And, having thereupon “made some essays,” he “found encouragement to proceed further, and

\* The old commune of Marais, now annexed to the town, derived its name from the workman in which the oil was pressed.

LILY, *Lilium*, the typical genus of *Liliaceae*, embraces nearly fifty species, all confined to the northern hemisphere, about fifteen being natives of Japan and China, six of the mountains of India, eight of south Europe, five of the east and nine of the west coasts of North America. The earliest in cultivation were described in 1597 by Gerard (*Herball*, p. 146), who figures eight kinds of European (true) lilies, viz., *L. album* (*L. candidum*, L.), and a variety, *L. bizantinum*, two umbellate forms of the type *L. bulbiferum*, Park., named *L. aureum* and *L. cruciatum latifolium*, and three with pendulous flowers, apparently forms of the martagon lily. Parkinson, in his *Paradisus* (1629), described five varieties of martagon, six of umbellate kinds—two white ones, and *L. paeponium*, *L. chalcidonicum*, *L. carniolicum*, and *L. pyrenaicum*—together with one American, *L. canadense*, which had been introduced in 1629. For the ancient and mediæval history of the lily, see M. de Caumont d'Hamule's *Monographie historique et littéraire des Lis* (Malines, 1870). Since that period many new species have been added. The latest authorities for description and classification of the genus are J. G. Baker ("Revision of the Genera and Species of *Tulipeae*," *Journ. of Linn. Soc.*, xiv. p. 211, 1874) and J. H. Elwes

LILLYE, WILLIAM G. 1466-1523), one of the introducers of a knowledge of the Greek language into England, was born at Odiham, in or about the year 1466. He entered the university of Oxford in 1484, became a demy of Magdalen in 1486, and after taking his first degree in arts went on a pilgrimage to Jerusalem. On his return he put in at Rhodes, which was still occupied by the Knights, under whose protection many Greeks had taken refuge after the taking of Constantinople by the Turks. Here he laid the foundation of a knowledge of the Greek language. We next hear of him in Italy, following the lectures of John Sulpitius and Pomponius Laetus at Rome. From this he passed on to Venice, from which place he wrote to his friend and patron Thomas Starkey, that "he is assiduously attending the lectures of Egnatius in Latin, but that he finds no one in Venice who can assist him in the study of Greek. He reads, however, Greek by himself, and has

read seven plays of Sophocles, five of Euripides, three of Aristophanes, besides extracts from Xenophon and Plutarch, by himself without a teacher." After his return he settled in London, as a private teacher of grammar, and is believed to have been the first who taught Greek in that city. In 1510 Colet, dean of St Paul's, who was then founding the school which afterwards became famous, appointed Lilye the first highmaster. He held this office only twelve years, dying of the plague in February 1523.

Lilye's name deserves commemoration, not only as one of the pioneers of Greek learning, but as one of the joint authors of a book, familiar to many generations of students, down to the present century, the old Eton Latin grammar. The *Brevissima Institutio*, a sketch by Colet, corrected by Erasmus, and worked upon by Lilye, contains two portions, the authorship of which is indisputably Lilye's. These are the lines on the genders of nouns, beginning "Propria quæ naribus," and those on the conjugation of verbs, beginning "As in presenti." The "Curmen de moribus" bears Lilye's name in the early editions: but Hearne asserts that it was written by Leland, who was one of his scholars, and that Lilye only adopted it. Besides the *Brevissima Institutio*, Lilye wrote a variety of Latin pieces both in prose and verse. Some of the latter are printed along with the Latin verses of Sir Thomas More in *Progymnasmata Thomæ Mori et Gulielmi Liliæ Sodaliū*, Basel, 1518. Another volume of Latin verse directed against a rival schoolmaster and grammarian, Whittington, whose grammar that of Lilye superseded, is entitled *Antibossion ad Gulielmum Hornetium*, 1521.

The only authority for the few facts which make up the above life of Lilye is a short sketch furnished by his son George to Paulus Jovius, who was collecting for his history the lives of the learned men of Great Britain. All the other names, such as Bale, Pits, Fuller, Wood, which figure in the dictionaries as authorities, are only transcripts of George Lilye. To these scanty memoranda the present article adds an extract from three letters of Lilye's preserved in the British Museum, Cotton. Nero. B. vi. fol. 157, now printed for the first time.

LIMA, capital of the republic of Peru, as also of the department and province of Lima, is situated on an extensive plain, 500 feet above the sea-level, and 7 miles east from its port Callao on the Pacific coast, in 12° 2' 34" S. lat., 77° 7' 36" W. long. The general configuration of the main portion of the city, previous to 1870 surrounded by walls, is that of an irregular triangle, whose base rests on

temperature not excessive. The summer commences in December, and the winter in June, and the mean temperature for the year is about 73° Fahr. The city is divided into five quarters or parishes, and is well laid out with broad and regular thoroughfares, the streets intersecting one another at right angles. The houses are spacious, but generally of only two stories, and are approached by portals leading into an open court or yard. In the principal square, which covers an area of 9 English acres in the centre of the city, stands a fine fountain of bronze. Here also are the cathedral, a stone structure with two lofty towers and a broad façade, the archiepiscopal palace, the Government house, and the Portal de los Escribanos, containing the municipal offices and archives. Besides the cathedral there are five chief parochial and sixty-two other churches and chapels, and numerous monasteries and convents. Of the churches, the largest is that of San Pedro (1598), which has seventeen altars; of the religious houses that of the Dominicans is the finest, and that of the Franciscans the most extensive. The university, built in 1576, is the oldest in America; it contains the hall and offices

used by the chamber of deputies. Lima has more than seventy schools, a public library containing upwards of forty thousand volumes, and many charitable institutions, several of them connected with the religious orders. The principal place of amusement is the amphitheatre for bull-fights in the Plaza del Acho, accommodating nine thousand spectators. In the Plaza de la Exposicion is a marble statue of Columbus unveiling a figure of America. Of the many other monuments in Lima the most famous is the bronze equestrian statue of Simon Bolivar in the Plaza de la Independencia (or de Bolivar), 11 tons in weight, commemorating the battle of Ayacucho, which secured the independence of Peru. Among the public promenades are reckoned the cemetery outside the Maravillas gate, and the Paseo de la Alameda de los Descalzos, in the centre of which is a gorgeous garden. As the capital of Peru, Lima is one of the most important trading centres in South America. It has, however, but few home industries, its manufactured goods being chiefly imported from Europe via Callao, the medium of nearly all its foreign commerce. Several attempts have from time to time been made to establish factories, but the high

FIG. 1.—Neighbourhood of Lima and Callao.

the river Rimac, which separates the city from its offshoot or suburb of San Lazaro. Sheltered on the north and east by the spurs of the Andes, the city is exposed to the winds prevailing from the south-east, as also to those from the south and west. Although the atmosphere is moist, and the transitions of the seasons are rapid, the climate is not unhealthy, the rainfall being slight, and the variations of

price of labour has hitherto prevented any efforts on a large scale being permanently successful. There are, however, manufactories for tallow, soap, sperm caudles, glue, gold lace, gilt leather, and silver filigree work, and the capital supplies the towns of the republic with coarse woollen fabrics. The market is attended daily by about a thousand dealers. Fish is supplied from Callao, and vegetables partly from gardens in the city and environs, and partly from the native villages. Since 1857 the water for drinking purposes has been obtained filtered from the Rimac, and supplied by pipes to the houses. The imports are various; the exports include guano, cinchona, Indian wool, raw cotton, hides, sugar, saltpetre, gold, silver, and other minerals. Under ordinary conditions the imports and exports together exceed £5,000,000 annually. There are railways from Lima leading to Callao, Chancay, Chorrillos, and Oroya; the construction of several other lines has been stopped by the war with Chili. In 1780 the population of Lima was 50,000; in 1860 it had reached 100,341, and in 1865 121,362, of whom 38,761 were foreigners. A recent estimate (1877) gives the number at about 200,000, but, considering the vicissitudes the city has since then endured, these figures must be considered at the present time (1882) as far too high. The Spanish natives have the reputation of being courteous, affable, and generous, but at the same time fond of pleasure, improvident, and superstitious. By confession they are mostly Roman Catholics.

Lima was founded 18th January 1535, by Francisco Pizarro, who named it *Ciudad de los Reyes* in honour of the emperor Charles V. and Doña Juana his mother, or, according to some authors, from its site having been selected on the 6th January, the Feast of the Epiphany. The name afterwards gave place to that of *Lima*, Spanish corruption of the Quichua word *Li*. In 1548 Lima received its first archbishop, and in 1582 the earliest provincial council for the state was held there. Remaining under Spanish rule during the 17th, 18th, and early part of the 19th centuries, the city continued to increase in prosperity, though it was visited by terrible earthquakes, of which the most disastrous was that of the 28th October 1746, when 5000 of the inhabitants perished and the port of Callao was destroyed (see CALLAO, vol. iv. p. 107). On the 12th July 1821, after a siege of some months, Lima was entered by a Chilean force under General San Martín, who on the 28th was proclaimed protector of Peru as a free state, but its independence was not finally secured until after the victory of Ayacucho (9th December 1824). In March 1828 the city again suffered from an earthquake, and in 1854–55 the yellow fever carried off a great number of the inhabitants. On the 11th of August 1857, Mr Sullivan, British minister to Peru, was assassinated. In November 1864 a congress of plenipotentiaries from Chili and other South American states was held here to concert measures of mutual defence. Of the various revolts which have during the last few years taken place at Lima may be mentioned that of November 1865, when President Pezet was displaced for Causeco; the riots against religious toleration, 15th April 1867; and the military insurrection, 22d July 1872, when Gutiérrez, minister of war, arbitrarily assumed power, had President Balta imprisoned and shot, but himself soon fell a victim to the popular fury; order being afterwards with difficulty restored by Vice-President Zavallos. In consequence of the ill-success of the war with Chili, Lima towards the close of 1879 was again in an unsettled condition; President Prado fled, and on the 22d December, after a sanguinary coup d'état, Pierola was proclaimed dictator. In April 1880 Callao was blockaded by Chilean war ships, and Lima had to be placed in a state of defence. On the 20th of November the Chilean army effected a landing at Pisco, a fortified place about 100 miles south of Lima, and, having afterwards advanced upon the capital, forcibly occupied it upon the 17th of January 1881.

**LIMA**, capital of Allen county, Ohio, U.S., on the Ottawa river, and at the intersection of four railway lines, 130 miles north of Cincinnati. It is pleasantly situated

in a fine farming country, and has two large railway repairs shops, extensive car-works, and other smaller manufactories. The population in 1850 was 757; in 1860, 1989; in 1870, 4464; and in 1880, 7567.

**LIMBORCH**, PHILIP VAN (1633–1712), a prominent Remonstrant theologian, was born June 19, 1633, at Amsterdam, where his father held a good position in the legal profession. He received his education at Utrecht, at Leyden, in his native city, and finally at Utrecht university, which he entered in 1652. In 1657 he became a Remonstrant pastor at Gouda, and in 1667 he was transferred to Amsterdam, where, in the following year, the office of professor of theology in the Remonstrant seminary was added to his pastoral charge. He died there on April 30, 1712.

His most important work, *Institutiones theologice christianae, ad praeceptum purae christianae aequae, directae* (Amsterdam, 1686, 5th ed. 1745), remains undisturbed as a full and clear exposition of the system of Episcopius and Cocceius. The fourth edition (1715) included a posthumous "Latino-historiae de origine et progressu controversiarum in doctrina Belgio de praedestinatione." Limborch also wrote *De veritate religionis Christianae auctoritate auctoritate Testarum*, Gouda, 1687; *Historia Inquisitionis* (1692), in four books prefixed to the "Liber Sententiarum Inquisitionis Tolosanae" (1697, 1724), and *Concursus in Acta Apostolorum et in Epistolam Romanam et ad Hebraeos*, Rotterdam, 1711. His editorial labours included the publication of various works of his predecessors, and of *Epistola ecclesiastica praesentium de traditionum veterum* (Amsterdam, 1684), chiefly by Amminius, Cyrenobogardus, Volturnus, Voetsius, Goutius, Episcopius (his granduncle), and Balaeus; they are of great value for the history of Arminianism. An English translation of *Theologia*, "with improvements, from Walker, Tillotson, Scott, and others," was published in the beginning of last century by W. Jones (*A Complete System or Body of Theology, both Speculative and Practical, founded on Scripture, and Reason*, London, 1702), and a translation of *History of the Low Countries* by S. Chamber, with "a large introduction containing the rise and progress of persecution and the real and pretended causes of it" prefixed, appeared in 1751.

**LIMBURG**, or LIMBOURG, one of the nine provinces of Belgium, is bounded on the N. and E. by Holland, on the S. by the province of Liège, and on the W. by those of Brabant and Antwerp; the area is 932 square miles, with a population, in 1880, of 211,691. The surface is for the most part flat, but rising somewhat towards the south east. Most of the province is included in the barren and marshy district of sandy heath known as *La Campine* (Flem., *Kempen*). The Meuse, with a tolerably fertile valley, is its chief river. The soil is metaliferous; the chief vegetable products are cereals, leguminous plants, flax, hemp, and betroot; and stock breeding is largely carried on. Industries are less developed in Limburg than in the rest of Belgium; but the distilleries of the province are very considerable and noted. Limburg is divided for administrative purposes into three arrondissements, of which the capitals are Hasselt (population 11,500), Tongres (7600), and Maeseyck (4100). The last named is the birthplace of Hubert and John van Eyck, the Flemish painters. One of the most interesting towns of the province is St Trond (*q.v.*), thought to be the ancient *Atuatum Oppidum*, the oldest town in Belgium. Near Tongres is a mineral well, described by Pliny.

The territory of Limburg was that of the *Eburones*, whom the Romans exterminated, and was afterwards inhabited by the *Tungri*, and *Paradi*. . . It was one of the first conquests of the invading Franks, who established themselves and proclaimed their first kings there. In the Middle Ages it constituted the county of Loos, holding of the bishop of Liège; afterwards it became the duchy of Limburg, which was taken possession of in the 13th century by the duke of Brabant. From the 14th to the end of the 18th century the duchy included only a small portion of the present province; it extended eastward from the Meuse as far as to Aix-la-Chapelle, and southward to the Vesdre. In the 16th century Limburg remained in the possession of Spain, and it passed to Austria in 1713. After the treaty of Campo Formio (1797) it became a French department, Meuse-Inférieure, with Maestricht as capital. By the treaty of

Vienna (1815) it formed one of the nineteen provinces of the kingdom of the Netherlands, and by that of London (1831) the eastern portion was ceded to Holland, becoming a Dutch province, the remainder constituting the present province of Belgium.

**LIMBURG**, or **LIMBOURG**, one of the eleven provinces of Holland, is bounded on the W. by Belgium (Limbourg) and North Brabant, on the N. by North Brabant and Guelderland, on the E. by Rhenish Prussia, and on the S. by Belgium (Liège), and has an area of 851 square miles, with a population in 1876 of 235,135 (97 per cent. being Roman Catholics). The surface, which is flat, is partly covered with heaths and fens; of the latter the most considerable is the "peel" or marsh in the north, which extends into North Brabant. The province is traversed by the Maas, of which the chief affluents here are the Geule, the Geleen, and the Roer, all on the right; means of water communication are also supplied by the Zuid Willem's canal and its branches. The agricultural products are similar to those of Belgian Limburg; bee-keeping is also engaged in. Coal occurs within the province, and there is a mine at Kerkrade. The arrondissements are two in number,—Maastricht and Roermonde, —Maastricht being the capital. For the history of the province see the preceding article.

**LIMBURG**, a town in the circle of Unterlahn and district of Wiesbaden, Prussia, is situated 360 feet above the sea level, on the Lahn, here crossed by a bridge dating from 1315, and on the Nassau Railway midway between Coblenz and Wetzlar. A local branch line connects it with Hadamar. It is the seat of a Catholic bishop, and has one evangelical and four Catholic churches. The only prominent architectural feature is the small seven-towered semi-Byzantine cathedral, picturesquely situated on a rocky site overhanging the river; it was founded by Conrad Kunbold, count of Niederlahngau, in 905, and finally consecrated in 1235 (restored 1872-78). Limburg has a seminary for the education of priests, and a variety of schools; the industries, which are unimportant, include manufactures of cloth, tobacco, machinery, pottery, and leather. The population in 1875 was 5161.

Limburg, which was a flourishing town during the Middle Ages, passed in 1494 into the possession of the archbishops of Treves after the extinction of its own line of counts, and in 1803 fell to the duke of Nassau. It was the scene of a victory of the archduke Charles of Austria over the French under Jourdan on September 16, 1794. It possesses an interesting MS. fragment of its chronicles, the *Recht der Limburger*. The record which is supposed to have been the recorder Limburg in 1494, additions being made by subsequent copyists; the document, which has been more than once printed, is valuable especially for the ancient rhymes it embodies, and for its notices of old German poets.

**LIMBUS**. The *Limbus Infantum* or *Puerorum* in mediæval theology is the "margin" or "border" (limbus) of hell to which human beings dying without actual sin, but with their original sin unwashed away by baptism, were held to be consigned; the category included, not unbaptized infants merely, but also idiots, cretins, and the like. The word "limbus," in the theological application, occurs first in the *Summa* of Thomas Aquinas; for its extensive currency it is perhaps most indebted to the *Commedia* of Dante (*Inf.*, c. 4). The question as to the destiny of infants dying unbaptized presented itself to theologians at a comparatively early period, and received very various answers. Generally speaking it may be said that the Greek fathers inclined to a cheerful and the Latin to a gloomy view. Thus Gregory of Nazianzus (*Orat.* 40) says "that such children as die unbaptized without their own fault shall neither be glorified nor punished by the righteous Judge, as having done no wickedness, though they die unbaptized, and as rather suffering loss than being the authors of it." Similar opinions have been expressed by Gregory of Nyssa, Severus of Antioch, and others,—

opinions which it is almost impossible to distinguish from the Pelagian view that children dying unbaptized might be admitted to eternal life, though not to the kingdom of God. In his recoil from Pelagian heresy, Augustine was compelled to sharpen the antithesis between the state of the saved and that of the lost, and taught that there are only two alternatives,—to be with Christ or with the devil, to be with Him or against Him. Following up, as he thought, his master's teaching, Fulgentius declared that it is to be believed as an indubitable truth that, "not only men who have come to the use of reason, but infants dying, whether in their mother's womb or after birth, without baptism in the name of the Father, Son, and Holy Ghost, are punished with everlasting punishment in eternal fire." Later theologians and schoolmen followed Augustine in rejecting the notion of any final position intermediate between heaven and hell, but otherwise inclined with practical unanimity to take the mildest possible view of the destiny of the irresponsible and unbaptized. Thus the proposition of Innocent III. that "the punishment of original sin is deprivation of the vision of God" is practically homologated by Thomas, Scotus, and all the other great theologians of the scholastic period, the only outstanding exception being that of Gregory of Rimini, who on this account was afterwards called "tortor infantum." The first authoritative declaration of the Latin Church upon this subject was that made by the second council of Lyons (1274), and confirmed by the council of Florence (1439), with the concurrence of the representatives of the Greek Church, to the effect that "the souls of those who die in mortal sin or in original sin only forthwith descend into hell, but to be punished with unequal punishments." Perrone remarks (*Præf. Theol.*, pt. iii. chap. 6, art. 4) that the damnation of infants and also the comparative lightness of the punishment involved in this are thus *de fide*; but nothing is determined as to the place which they occupy in hell, as to what constitutes the disparity of their punishment, or as to their condition after the day of judgment. In the council of Trent there was considerable difference of opinion as to what was implied in deprivation of the vision of God, and no definition was attempted, the Dominicans maintaining the severer view that the "limbus infantum" was a dark subterranean fireless chamber, while the Franciscans placed it in a lightsome locality above the earth. Some theologians continue to maintain with Bellarmine that the infants "in limbo" are affected with some degree of sadness on account of a felt privation; others, following Sfrondati, hold that they enjoy every kind of natural felicity, as regards their souls now, and as regards their bodies after the resurrection, just as if Adam had not sinned. In the condemnation (1794) of the synod of Pistoia (1786), the twenty-sixth article declares it to be false, rash, and injurious to treat as Pelagian the doctrine that those dying in original sin are not punished with fire, as if that meant that there is an intermediate place, free from fault and punishment, between the kingdom of God and everlasting damnation.

The *Limbus Patrum*, *Limbus Inferni*, or *Sinus Abrahamæ* is defined in Roman Catholic theology as the place in the underworld where the saints of the Old Testament were confined until liberated by Christ on his "descent into hell." Regarding the locality, and its pleasantness or painfulness, nothing has been taught as *de fide*, and opinions have been various. It is sometimes regarded as having been closed and empty since Christ's descent, but other authors do not think of it as separate in place from the *limbus infantum*. The whole idea, in the Latin Church, has been justly described as the mere caput mortuum of the old catholic doctrine of hades, which was gradually superseded in the West by that of purgatory.

**LIME** is the name of the strongly basic monoxide  $\text{CaO}$  of the metal calcium. This base is widely diffused throughout the three kingdoms of nature in the form of salts, of which the carbonate  $\text{CaCO}_3$  and the hydrated sulphate  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  are by far the most abundant. Both are found in the mineral kingdom in a variety of forms. Of native carbonates of lime, *calc-spar* (Iceland spar), though comparatively rare, may be mentioned first as representing the purest native form of the compound. It generally presents itself in the form of well-developed transparent colourless rhombohedra, which possess to a remarkable degree the property of producing double refraction of light, whereupon is founded its application in the construction of certain optical instruments. Of the varieties of massive or crystalline carbonate of lime, those which, through the fineness of their grain and other qualities, lend themselves for the purposes of the sculptor go by the name of marble, while the remainder are embraced under the generic term of limestone. This name, however, is understood to exclude chalk, a soft, amorphous variety which, according to Ehrenberg, consists mainly of *Foraminifera* shells. All limestones contain at least traces of magnesia. When this foreign base is present in considerable proportion the rock is termed "dolomite" (see MAGNESIUM). Among the native forms of (hydrated) sulphate of lime the mineral "selenite" (glacies Mariæ) corresponds to Iceland spar among the carbonates. It forms colourless transparent rhombohedral prisms, generally united into "twins," and flattened down into plates readily cleavable along plane parallel to the surface. Hardness ranges from 1.5 to 2; the specific gravity is 2.3. Far more common than selenite are massive varieties known as ALABASTER (see vol. i. p. 439) and ordinary GYPSUM (vol. xi. p. 337).

Both sulphate and carbonate of lime, apart from their occurrence as independent minerals, are almost universally diffused throughout the earth's crust, and in the waters of the ocean. Now the sulphate is appreciably soluble in even pure water, while the carbonate, though practically insoluble in pure, is quite decidedly soluble in carbonic acid water. As all atmospheric water must necessarily hold carbonic acid gas in absorption, most natural waters, and certainly all deep-well waters, are contaminated with more or less of bicarbonate or sulphate of lime, or with both. When such a water is being boiled, there is an escape of the free and the loosely combined carbonic acid, and the carbonate of lime comes down as a loose precipitate or as a "crust"; and, when the water is sufficiently concentrated by evaporation, the sulphate likewise is partly deposited. The decomposition of the "bicarbonate" in fact takes place, though slowly, even at ordinary temperatures, when the water in which it is held in solution is exposed to the atmosphere. It is in this manner that stalagmites and stalactites frequently seen within rock-caverns are produced, and there is no difficulty in accounting for the grotesque and fantastic forms which the latter often exhibit.

**Quicklime.**—The native carbonate always serves as the starting-point in the preparation of calcium compounds. From it the oxide  $\text{CaO}$ , known as quicklime or caustic lime, is produced industrially by heating limestone or marble in kilns, between layers of fuel, which in the United Kingdom is generally coal. The carbonic acid goes away with the gaseous products of combustion, and the oxide remains in unfused lumps of the form of the original stones. Lime, when pure, is an amorphous white solid, which is absolutely infusible and non-volatile; and on this account, when raised to high temperatures, it emits a brilliant white light ("lime-light"). The commercial article is generally grey or otherwise discoloured by the presence of foreign metallic oxides.

The decomposition that goes on in a limekiln is not brought about by the effect of heat alone. Gay-Lussac found long ago that carbonate of lime, when heated to intense redness in a closely covered crucible, loses its carbonic acid only very slowly, while the acid goes off readily even at somewhat lower temperatures when a current of steam is passed over the heated limestone. This may be accounted for by assuming that the steam, in the first instance, produces hydrate from the carbonate of lime, which latter then at once breaks up into its two components. More probably, however, the steam acts only by producing a *partial* vacuum, that is, by clearing out the carbonic acid which it allowed to stagnate even at high temperatures, would react on the quicklime produced, thus preventing the decomposition of a portion of the carbonate.

Quicklime acts readily and energetically on water, with evolution of much heat (269 units per unit weight of lime, Berthelot) and formation of a bulky white powder of the hydrate  $\text{Ca(OH)}_2$  or  $\text{Ca(OH)}_2$ . This powder readily mixes with water into a smooth paste, which may be diluted to a milky liquid—milk of lime. This, when filtered through paper, yields "lime water," a strongly alkaline liquid containing about  $\frac{1}{1000}$ th of its weight of lime (calculated as  $\text{CaO}$ ). When boiled it deposits a part of its dissolved lime as such, and when exposed to ordinary air it quickly draws a skin of carbonate of lime. Hence its application as a reagent for carbonic acid, and the extensive use of milk of lime (whitewash) as a cheap white pigment in wall-painting. Lime paste, as every one knows, is most extensively used as a mortar or cement for bricks and stones in building. For this purpose it is always mixed with a certain proportion of sand. This admixture in all probability was originally intended only to save lime and prevent shrinking. But it is now generally assumed to have a chemical function, causing the formation of a hard silicate of lime pervading and thus strengthening the mortar. Some chemists deny the practical importance though not the occurrence of this silication, what admits of no doubt is that the hardening of mortar involves the very gradual conversion of the original hydrate into carbonate of lime. Under the name of plaster, a fine smooth paste of lime and sand, with short hair to increase the tenacity of the mixture, is a most important material for coating the internal walls and roofs of ordinary buildings.

**Hydraulic Cements.** Ordinary mortar, on account of the solubility of lime in water, is unfit for aquatic masonry; for this purpose hydraulic cements must be used. Of these there are a great variety, which, however, mostly agree in this that they consist of calcined mixtures of limestone and clay (preferably alkaliferous clay) and other silicates. By calcining such mixtures at temperatures short of that at which a glass would be produced, the lime becomes caustic, and part of the caustic lime, by uniting with the clay (and silicate generally), forms a silicate sufficiently basic to be disintegrable by acids and even by water. When such cement, as a powder, is mixed with water, the lime acts upon the silicate of alkali and the gelatinous silica hydrate temporarily produced, and with the silica and alumina and oxide of iron unites into a hard, waterproof, very complex, silicate mixture.

H. Ste. Claire Deville having found that magnesia has hydraulic properties, hydraulic cements have been made by calcining dolomites of the proper composition so far as to decompose only the carbonate of magnesia (into  $\text{MgO}$  and  $\text{CO}_2$ ). See CEMENT, vol. v. p. 328.

Lime, being the cheapest of powerful bases, is largely used in chemical manufacturing. It serves for the causticizing of soda, for the preparation of ammonia from ammonia salts, and for the manufacture of bleaching powder. It also enters into the composition of certain kinds of glass, and is used (as lime or as carbonate), in the making of soda ash.

**Lime Salts.** These can in general be prepared by the saturation of the respective acids with lime hydrate. Thus the pure ...

bonate  $\text{CaCO}_3$  may be prepared by passing carbonic acid into lime-water. But a more convenient method is to decompose a solution of pure chloride of calcium with excess of carbonate of ammonia, preferably at 70–80° C., when the carbonate assumes the form of a crystalline precipitate which settles readily and is easily washed with hot water. The sulphate (artificial gypsum) appears as a voluminous white precipitate, consisting of minute colourless needles, when sulphuric acid is added to a not too dilute solution of chloride of calcium or other lime salt. The precipitate  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  is appreciably soluble in water, 1000 parts of which at 0°, 35°, and 100° C. dissolve 2.05, 2.54, and a little over 2 parts respectively of gypsum. The hydrated sulphate at temperatures exceeding 110° C. loses its water. The anhydrous sulphate, if formed below about 200° C., readily recombines with water into compact gypsum (plaster of Paris). By exposure to high temperatures (500° C. and upwards) sulphate of lime loses its power of recombining with water; at very high temperatures it fuses. A naturally anhydrous sulphate of lime (anhydrite) occurs in association with rock salt, and otherwise, as a not very common mineral.

The well-known favourable action of gypsum as a manure, more especially for clay (see AGRICULTURE), has lately been explained by Dehérain on the strength of analyses and vegetation experiments of his own, by assuming that it converts the carbonate of potash of the soil into sulphate, which, being less obstinately retained by the soil, more readily finds its way into the roots of the plants.

*Chloride of Calcium* (anhydrite of lime),  $\text{CaCl}_2$ , is prepared by dissolving marble or limestone in aqueous muriatic acid. The iron and manganese generally present as impurities can be eliminated, after peroxidation by chlorine water, by digestion with hydrate of lime, which also, at allowed sufficient time, removes the magnesia. The filtrate is acidified with hydrochloric acid and concentrated by evaporation, so far that, on cooling, it deposits part of the dissolved salt as crystals. These have the composition  $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$ . They are very easily soluble in water and alcohol, and highly hygroscopic. Hence the salt is used occasionally to keep textile fibres moist, and in a fit state for being woven. The crystals when kept in a vessel at about 200° lose about two-thirds of their water, and leave that porous kind of chloride of calcium which analytical chemists prefer for the drying of gases. This substance, when heated to redness, which must be done in platinum to prevent contamination, loses the rest of the water and (at 723° C., Carnelley) fuses into the anhydrous salt  $\text{CaCl}_2$ , which on cooling hardens into a stone-like mass. In this final process of dehydration, however, part of the chlorine goes off as hydrochloric acid, so that the product obtained is contaminated with some oxychloride. This can be prevented by igniting the salt with sub-ammonic or more surely by effecting the dehydration in a current of anhydrous hydrochloric acid gas. Anhydrous chloride of calcium is much used in laboratories as a powerful dehydrating agent. It combines with ammonia gas into a solid compound. It dissolves in methyl alcohol and methyl dehyd, forming crystallizable "alcoholates" (Graham), compounds of  $\text{CaCl}_2$  with "crystall alcohol."

*Nitrate of Calcium*,  $\text{Ca(NO}_3)_2$ , crystallizing with  $\text{H}_2\text{O}$ , is a very hygroscopic salt, soluble in even absolute alcohol. It is mentioned here as a material for the convenient preparation of pure lime, by simple ignition of the salt in a platinum crucible. Regarding *blende of potash*, a double salt of hypochlorite and chloride of calcium  $\text{Ca} \cdot \text{ClO} \cdot \text{CaCl}_2$ , see CHLORINE, vol. v. p. 678.

*Fluoride of Calcium*,  $\text{CaF}_2$ , obtainable by precipitation of chloride of calcium with an alkaline fluoride, occurs in nature as Fluorapatite (*q.v.*). Fluoride of calcium is widely disseminated throughout the mineral kingdom as an admixture with other minerals. All native forms of phosphate of lime contain it; some in considerable quantity. Traces of it are found in bones and in the ashes of most plants.

*Metallic Calcium* cannot be prepared by the reduction of the oxide with charcoal. It may be produced, however, by the electrolysis of the fused chloride or more conveniently by heating the fused  $\text{CaCl}_2$  even parts with sodium, one part of an non-metallic. The metal has a yellow colour; it is somewhat harder than lead, and very malleable, and ductile (see Besant and Johnson). The specific gravity is 1.578 (Dumas and Matheson). It does not tarnish in dry air, but readily decomposes water, with evolution of hydrogen and formation of hydrate of lime. It is practically non-volatile. When heated in air or oxygen it burns with a most brilliant light into oxide (*q.v.*).

*Tests.* Solutions of ordinary calcium salts are not affected visibly by sulphuric acid, hydrogen sulphide of ammonium, or pure ammonia. Carbonate of calcium, even in the presence of sal ammoniac, precipitates the carbonate. So far calcium behaves like barium and strontium. From the former it is distinguished by its not being precipitated by either hydrofluosilicic acid or bichromate of potash, and from both by its spectrum and the relatively large solubility of its sulphate in water. The latter is obtained from any calcium solution by addition of sulphuric acid and alcohol. The sulphate is washed with alcohol on a filter. When then boiled with water it yields a solution which, dilute as it is, gives a very distinct pre-

cipitate with oxalate of ammonia (barium and strontium sulphates in these circumstances give negative results). Oxalate of ammonia is the most delicate precipitant for calcium; the precipitate is insoluble in water, in ammonia and ammonia salts, and in acetic acid. From solutions (in acids) of phosphate or oxalate of calcium ammonia and likewise sulphide of ammonium precipitate the metal as phosphate or oxalate. To detect it in such a precipitate, dissolve in hydrochloric acid and add sulphuric acid and alcohol. The calcium is precipitated as sulphate, which can be identified as just explained.

For the phosphates of lime, see PHOSPHATES.

(W. D.)

**LIME, or LINDEN.** The lime trees, species of *Tilia*, are familiar timber trees with mellifluous flowers, rarely if ever maturing their fruit in England, which are borne on a common peduncle proceeding from the middle of a long bract. *T. europæa*, L., is indigenous to Europe, excepting the extreme north, and extends eastwards across Russian Asia to the Altai. The lime is much planted in Britain, and is probably wild in south and west England, and perhaps in Ireland. The truly indigenous form in north Europe is always a small-leaved one. The large leaved variety (*T. grandifolia*, Ehrh.) is of South-European origin (Bentham, *Handbook of the British Flora*, i. 157); *T. parvifolia*, L., is perhaps the English wild form of the Continental *T. europæa*, L.; while *T. intermedia*, D. C., probably a sub-species of *T. europæa*, L., is the so-called common lime (Hooker, *Student's Flora of the British Isles*, p. 76). For a full description of the European and American forms, see Loudon, *Arboretum*, i. p. 364, and De Candolle, *Prod.*, i. 513. The lime sometimes acquires a great size: one is recorded in Norfolk as being 16 yards in circumference, and Ray mentions one of the same girth. The famous linden tree which gave the town of Neustadt in Wurtemberg the name of "Neustadt an der grossen Linden" was 9 feet in diameter.

The economic value of the tree chiefly lies in the inner bark or liber, called bast, and the wood. The former was used for paper and mats and for tying garlands by the ancients (*Od.*, i. 38; Pliny, xvi. 14, 25; xxiv. 8, 33). *T. grandifolia* and *T. parvifolia* have been found in the debris of lake dwellings in Switzerland. Bast mats are now made chiefly in Russia, the bark being cut in long strips, when the liber is easily separable from the corky superficial layer. It is then plaited into mats about 2 yards square; 14,000,000 come to Britain annually, chiefly from Archangel. The wood is used by carvers, being soft and light, and by architects in framing the models of buildings. Turners use it for light bowls, &c. The flowers, alone, are used for an infusion in Austria and elsewhere, with much success in vertigo and spasms, producing perspiration, and alleviating coughs; but the bracts and fruit are astringent.

The common lime was well known to the ancients. Theophrastus says the leaves are sweet and used for fodder for most kinds of cattle. Pliny alludes to the use of the liber and wood, and describes the tree as growing in the mountain valleys of Italy (xvi. 30). See also Ving., *Geo.*, i. 173, &c.; Ov., *Mét.*, viii. 621, x. 92. The *φιλύρα* (Hdt., i. 67) was the lime of the Greeks, perhaps *T. argentea* (see Pakening's *Chron. Hist. of Plants*, pp. 214, 227, 418). Allusion to the lightness of the wood is made in Aristoph., *Birds*, 1378.

For the sweet lime (*Citrus Limetta*) and lime juice, see LEMON.

**LIMERICK**, a maritime county of Ireland, in the province of Munster, is bounded on the N. by the estuary of the Shannon and the counties of Clare and Tipperary, on the E. by Tipperary, on the S. by Cork, and on the W. by Kerry. Its greatest length from north to south is 35 miles, and its greatest breadth east and west 54 miles. The total area comprises 662,973 acres, or 1036 square miles.

The greater part of the county is comparatively level, and rests on limestone, but in the south-east the picturesque Galtees, which extend into Tipperary, and are composed of Silurian strata overlaid by Old Red Sandstone, attain in Galtymore a height of 3015 feet, and on the west stretching

into Kerry there is a circular amphitheatre of less elevated mountains composed of volcanic rocks. The Shannon is navigable to Limerick, above which are the rapids of Doonas and Castleroy. The Maig, which rises in the Galtees, and flows into the Shannon, is navigable as far as the town of Adare. Limerick includes the greater part of the Golden Vale, the most fertile district of Ireland, which stretches across the centre of the county from Cashel in Tipperary to near the town of Limerick. Along the banks of the Shannon there are large tracts of flat meadow land formed of deposits of calcareous and peaty matter, and possessing extraordinary fertility. The soil in the mountainous districts is, for the most part, thin and poor, and incapable of improvement. In 1880 there were 176,774 acres under tillage, 415,107 pasture, 8407 plantations, and 62,465 waste. The total number of holdings in 1880 was 16,286, of which 1937 were less than one acre, and 11,273 between 15 and 100 acres in extent, 1019 between 100 and 200 acres, 259 between 200 and 500 acres, and 29 above 1000 acres. The large farms occupy the low grounds, and are almost wholly devoted to grazing. The following table shows the area under the principal crops in 1855 and 1881:

	Wheat.	Oats.	Other Cereals.	Potatoes.	Turnips.	Other Crops.	Flax.	Meadow and Clover.	Total.
1855	17,149	45,455	12,057	35,723	11,394	2,771	214	71,292	196,084
1881	7,257	21,440	3,003	23,035	5,520	2,994	6	112,378	176,573

The table shows a remarkable increase in the area under meadow, notwithstanding which the total area under tillage has considerably decreased. The number of horses has, since 1855, declined from 17,206 to 15,389, of which 10,228 were used for agricultural purposes. Cattle have increased from 159,710 to 201,456, an average of 28 to every 100 acres under cultivation, the average for Ireland being 25.8. The number of cows was 95,225. Sheep have diminished from 80,914 to 50,599, and pigs from 61,733 to 48,801. The number of goats was 10,012, and of poultry 428,398.

According to the corrected return of 1878, the land, exclusive of that in the county of the city of Limerick, was divided among 1676 proprietors, possessing 660,386 acres, of the annual value of £161,213, or 13s. 11d. per acre. Of the owners nearly 40 per cent. possessed less than 1 acre, the average extent being 394. The following were the largest proprietors:—Earl of Devon, 33,026; Earl of Dunraven, 14,298; Lord Ashton, 11,273; Archdeacon Gould, 10,966; Lady Louisa Fitzgibbon, 10,316; Sir Croker Barrington, 9485.

**Manufactures.**—The inhabitants are employed chiefly in agriculture, but coarse woollens are manufactured, and also paper, and there are a considerable number of meal and flour mills. At one time there were a number of flax-spinning and weaving mills, but that industry is now almost wholly extinct.

**Administration and Population.** The county includes 14 baronies, 131 parishes, 2067 townlands, and the city and parliamentary borough of Limerick. The number of members returned to the Irish parliament was eight, two being returned for each of the boroughs of Askeaton and Kilmallock, in addition to the two returned as at present for the county, and the two returned for the county of the city of Limerick. There are three poor-law unions wholly within the county, and portions of four others. Assizes are held at Limerick, and quarter sessions at Bruff, Limerick, Newcastle, and Rathkeale. The county is within the Cork military district, with a brigade depot at Tralee. The population, estimated in 1760 at 92,376, had increased in 1821 to 277,477, and in 1841 to 331,003, but since that period it has been gradually diminishing, being 217,277 in 1861, and in 1881 only 177,203, of whom 86,541 were males and 90,662 females. The decrease since 1871 has been 7.7 per cent., the decrease per cent. in Ireland being 4.7. Besides the city of Limerick, with a population in 1881 of 48,240, only two other towns, Rathkeale and Newcastle, had a population of over 2000. From 1st May 1851 to 31st December 1880 the number of emigrants

from the county was 130,333, a proportion of 60 per cent. of the population in 1861.

**History and Antiquities.**—Limerick, originally inhabited by the Coriondi, was included in the kingdom of Thomond. Afterwards it had a separate existence under the name of Aine-Cliaich. From the 8th to the 11th century it was partly occupied by the Danes. By Henry II. it was granted to Henry Fitzherbert, but his claim was afterwards resigned, and subsequently various Anglo-Norman settlements were made. About 100,000 acres of the estates of the earl of Desmond, which were forfeited in 1586, were situated in the county, and other extensive confiscations took place after the Cromwellian wars. In 1709 a German colony from the Palatinate was settled by Lord Southwell near Bruff, Rathkeale, and Adare.

There are only slight remains of the round tower at Ardpatrick, but that at Carrigeen is much better preserved. There are important remains of stone circles, pillar stones, and altars on Loch Gur. In several places there are remains of old moats and tumuli. Besides the monasteries in the city of Limerick, the most important monastic ruins are those of Adare Abbey, Askeaton Abbey, Kilshane Abbey, Galbally Friary, Kilduff Monastery, Kilmallock Abbey, and Monaster-Nenagh Abbey. See the *History of Limerick* by Fitzgerald and McGregor, 1826-27.

LIMERICK, a county of a city, parliamentary borough, and the chief town of the county of Limerick, is situated on both sides of the Shannon, at the head of its estuary, and on an island of the river, 120 miles west south west of Dublin by rail. The western bank of the river is occupied by Irish Town, the island by English Town, and the eastern bank by Newtown Pery. The two former divisions consisting chiefly of mean houses occupied by the poorer classes, and Newtown Pery including the principal streets, shops, and public buildings. The different parts of the town are connected by several bridges, the most important of which is Wellesley bridge, erected in 1827 at a cost of £85,000. The cathedral of St Mary, founded in 1180, and rebuilt in

of Limerick.

1490, is a cruciform structure in the Gothic style, with an embattled tower 120 feet in height. A Roman Catholic cathedral in the First Pointed style was erected in 1860. The other principal public buildings are the court-house, the custom-house, the exchange, the chamber of commerce, the town hall, the county jail, the city jail, the infirmary, and Barrington's hospital. There are barracks for cavalry, artillery, and infantry. Limerick as a port occupies the fourth position in Ireland, and, while possessing secure and open communication with the Atlantic, is included in a vast network of inland navigation. Vessels of 1000 tons can unload at the floating dock, and vessels of 500 tons at the quays. A graving dock, admitting vessels of 1500 tons for repair, has lately been constructed. The value of the imports in 1880 was £837,269, the average for the four years 1876-79 being £940,279, and, for 1872-75

£873,533. For the same dates the value of the exports was £26,569, £9552, and £12,516. The principal industries are flax spinning and weaving, and the manufacture of lace and gloves. There are also breweries, distilleries, tanneries, and flour-mills. The population in 1851 was 48,961, which in 1871 had increased to 49,980, but in 1881 had diminished to 48,246.

Limerick is said to have been the ancient *Regia* of Ptolemy and the *Ross-d-Naugh* of the Annals of Mullingar. There is a tradition that it was visited by St. Patrick in the 5th century, but it is first authentically known as a settlement of the Danes, who in the middle of the 9th century made it one of their principal towns, but were expelled from it in the 11th century by Brian Boru. From 1169 till its conquest by the English in 1474 it was the seat of the kings of Thomond or North Munster, and, although in 1472 the kingdom of Limerick was given by Henry II. to Robert Fitz-herbert, the city was to remain in the possession of the Irish chieftains till 1490. By King John it was committed to the care of William de Burgh, who founded a French town, and for its defence erected a strong castle. The city was frequently besieged in the 15th and 16th centuries. In the 16th century its fortifications were extended to include Irish Town, and until their demolition in 1760 it was one of the strong fortresses of the kingdom. In 1602 it was taken by General Iremont, and after an unsuccessful siege by William III. in 1691 its resistance was terminated in October of the following year by the treaty of Limerick. The town obtained municipal privileges in 1499, and these were confirmed and extended by Edward I. and other sovereigns. In 1690 it received a charter constituting it a county of a city, and also incorporating a society of merchants of the staple, with the same privileges as the merchants of the staple of Dublin and Waterford. The powers of the corporation were remodelled by the Limerick Corporation Act of 1823. The prosperity of the city dates chiefly from the foundation of Newtown Pery by Mr. Sexton Pery in 1769. It returns two members to parliament. See the *History* by Landon, 1866.

**LIMITATION, STATUTES OF,** are Acts of Parliament by which rights of action are limited to a fixed period after the occurrence of the events giving rise to the cause of action. This is one of the devices by which lapse of time is employed to settle disputed claims. There are mainly two modes by which this may be effected. We may say that the active enjoyment of a right—or possession—for a determined period shall be a good title against all the world. That is the method known generally as *PRESCRIPTION* (*q.v.*). It looks to the length of time during which the defendant in a disputed claim has been in possession or enjoyment of the matter in dispute. On the other hand, the principle of the statutes of limitation is to look to the length of time during which the plaintiff has been out of possession. The point of time at which he might first have brought his action having been ascertained, the lapse of the limited period after that time bars him for ever from bringing his action. In both cases the policy of the law is expressed by the maxim *Interest reipublice ut sit finis litium*.

The principle of limitation was first adopted in English law in connexion with real actions, *i.e.*, actions for the recovery of real property. At first a fixed date was taken, and no action could be brought of which the cause had arisen before that date. By the Statute of Westminster the First (3 Edward I. c. 39), the beginning of the reign of Richard I. was fixed as the date of limitation for such actions. This is the well-known "period of legal memory" recognized by the judges in a different class of cases to which a rule of prescription was applied. Possession of rights *in aliena solo* from time immemorial was held to be a marketable title, and the courts following the statutes above mentioned held time immemorial to begin with the first year of Richard I.

A period absolutely fixed became in course of time useless for the purposes of limitation, and at last the method of counting back a certain number of years from the date of the writ was adopted in the Statute 32 Henry

years for various classes of actions named therein. A large number of statutes since that time have established periods of limitation for different kinds of actions. Of those now in force the most important are 21 James I. c. 16 for personal actions in general, and 3 & 4 Will. IV. c. 27 relating to actions for the recovery of land. The latter statute has been repealed and virtually re-enacted by the Real Property Limitation Act, 1874, which reduced the period of limitation from twenty years to twelve, for all actions brought after the 1st January 1879. The principal section of the Act of Will. IV. will show the *modus operandi*:—"After the 31st December 1833, no person shall make an entry or distress, or bring an action to recover any land or rent but within *twenty years next after the time at which the right to make such entry or distress or to bring such action shall have first accrued to some person through whom he claims, or shall have first accrued to the person making or bringing the same.*" Another section defines the times at which the right of action or entry shall be deemed to have accrued in particular cases; *e.g.*, when the estate claimed shall have been an estate or interest in reversion, such right shall be deemed to have first accrued at the time at which such estate or interest became an estate or interest in possession. Thus suppose lands to be let by A to B from 1830 for a period of fifty years, and that a portion of such lands is occupied by C from 1831 without any colour of title from B or A—C's long possession would be of no avail against an action brought by A for the recovery of the land after the determination of B's lease. A would have twelve years after the determination of the lease within which to bring his action, and might thus, by an action brought in 1891, disestablish a person who had been in quiet possession since 1831. What the law looks to is not the length of time during which C has enjoyed the property, but the length of time which A has suffered to elapse since he might first have brought his action.

It is to be observed, however, that the Real Property Limitation Act does more than bar the remedy. It extinguishes the right, differing in this respect from the other Limitation Acts, which, while barring the remedy, preserve the right, so that it may possibly become available in some other way than by action.

By section 14 of the Act of Will. IV., "when any acknowledgment of the title of the person entitled shall have been given to him or his agent in writing signed by the person in possession, or in receipt of the profits or rent, then the right of the person (to whom such acknowledgment shall have been given) to make an entry or distress or bring an action shall be deemed to have first accrued at the time at which such acknowledgment, or the last of such acknowledgments, was given. By section 15, persons under the disability of infancy, lunacy, or coverture, or beyond seas, and their representatives, are to be allowed ten years from the termination of this disability, or death (which shall have first happened), notwithstanding that the ordinary period of limitation shall have expired.

By 21 James I. c. 16, actions of trespass, detinue, trover, replevin, or account, actions on the case (except for slander), actions of debt arising out of a simple contract, and actions for arrears of rent not due upon specialty, shall be limited to six years from the date of the cause of action. Actions for assault, menace, battery, wounds, and imprisonment are limited to four years, and actions for slander to two years. Persons labouring under disabilities are allowed the same time after the removal of the disability. When the defendant is "beyond seas" (*i.e.*, outside the United Kingdom and the adjacent islands) a similar extension of time is allowed.

An acknowledgment, whether by payment on account or by mere spoken words, was formerly sufficient to take

the case out of the statute. The Act 9 Geo. IV. c. 14 (Lord Tenterden's Act) requires any promise or admission of liability to be in writing and signed by the party to be charged, otherwise it will not bar the statute.

Contracts under seal are governed as to limitation by 3 & 4 William IV. c. 42, which provides that actions for rent upon any indenture of demise, or of covenant, or debt, or any bond or other specialty, and on recognizances, must be brought within twenty years after cause of action. Actions of debt on an award (the submission being not under seal), or for a copyhold fine, or for money levied on a writ of *fiery facias*, must be brought within six years.

Of the miscellaneous limitations fixed by various Acts, the following may be noticed. Suits and indictments under penal statutes are limited to two years if the forfeiture is to the crown, to one year if the forfeiture is to the common informer. Penal actions by persons aggrieved are limited to two years (3 & 4 Will. IV. c. 42). Actions brought against a justice of the peace for acts done in the execution of his office are limited to six calendar months (11 & 12 Vict. c. 44). Acts done under any local or personal Act of Parliament can only be sued upon within two years (5 & 6 Vict. c. 97).

A defence under the statutes of limitations must in general be specially pleaded. Limitation is regarded strictly as a law of procedure. The English courts will therefore apply their own rules to all actions, although the cause of action may have arisen in a country in which different rules of limitation exist. This is also a recognized principle of private international law.

*United States.*—The principle of the statute of limitations has passed with some modification into the statute-books of every State in the Union except Louisiana, whose laws of limitation are essentially the prescriptions of the civil law drawn from the *Partidas*, or "Spanish Code." As to personal actions, it is generally provided that they shall be brought within a certain specified time—usually six years or less—from the time when the cause of action accrues, and not after, while for land the "general if not universal limitation of the right to bring action or to make entry is to twenty years after the right to enter or to bring the action accrues" (Bouvier's *Law Dictionary*, art. "Limitations"). The constitutional provision prohibiting States from passing laws impairing the obligation of contracts is not infringed by a law of limitations, unless it bars a right of action already accrued without giving a reasonable term within which to bring the action. (C. R.)

LIMOGES, capital of the department of Haute Vienne, France, and the ancient capital of Limon in, lies in the form of an amphitheatre on the right bank of the Vienne, 218 miles by rail south-south-west from Paris, on the Paris and Toulouse Railway, at its junction with the Charente line. It has also direct railway communication by Bellac with Poitiers. The population in 1876 was 59,011. In spite of many modern improvements and clearances, commencing with the administration of Turgot in 1762, the city still contains old quarters, which are dark, wretched, and unhealthy.

The cathedral, the most remarkable building, not only in the town but in the entire province, is in the Parisian Ogival style, and occupies the site of an old heathen basilica, which, according to tradition, was transformed into a Christian church by St Martial. The present edifice was built between 1273 and 1327, and has been quite recently restored, the north front of the transept, distinguished by the richness and perfection of its details, having been finally completed in 1851. The campanile is an elegant slightly leaning tower, 204 feet high. The interior of the church is remarkable for the boldness and elegance of its construction. It has a magnificent rood-loft, attributed to Bishop

Jean de Langeac (1533); close by the choir screen is the mausoleum of the same prelate. The glass was repaired in the 16th century, but is still undergoing restoration. Under the choir is the crypt of the old Roman church, containing frescos of the 11th century. Some of the houses still standing in Limoges date from the Middle

Plan of Limoges.

Ages; and commemorative tablets mark the birthplace of the chancellor D'Aguesseau and of Marshals Jourdan and Bugeaud. There is a museum of painting and sculpture, and, in connexion with the local industry, a very valuable ceramic museum. Limoges is the headquarters of the 12th army corps, and is also the seat of several learned societies, and of a court of appeal.

The principal industry is the manufacture of porcelain. The kaolin of St Yrieix is of such superior quality that it is exported even to America; the pearly tint used for enamel is obtained at Chanteloup, about 25 miles from Limoges, on the Paris railway. Thirty-five factories with eighty furnaces and fifty-four painting rooms (800 artists) employ 5800 workers of both sexes, and produce goods to the annual value of 12 millions of francs. There are many others in the immediate neighbourhood of the town. Limoges has also wool and cotton spinning-mills, and cloth factories, paper-work, foundries, &c. Shoemaking gives employment to 600 persons, and the manufacture of clogs to 250. There is an extensive trade in wine and spirits, cattle, cereals, and wool. The Vienne is navigable for rafts above Limoges, and the logs brought down by the current are stopped at the entrance of the town by the inhabitants of the Naveix quarter, who form a special guild for this industry.

Limoges was a place of importance even at the time of the Roman conquest, and sent ten thousand soldiers to the defence of Alesia. In 1190 it took the name of Augustus (*Augusta Treverorum*), but in the 14th century it was anew called by the name of *Limoges*, whose capital it was. It then contained palaces and fortifications, had its own senate and the right of coinage. (Tul. Hist. de France, viii.) Christianity was introduced by St Martial. In the 5th century Limoges was devastated by the Vandals, and in the 6th by the Visigoths. Viscounts were set over it by Clovis. It suffered again in the wars between the Franks and the people of Aquitaine, from Norman

invasion, and from a struggle which arose between two parties into which the city was divided, led by the abbot of St Martial and by the bishop respectively. During the Hundred Years' War it was taken again and again by the French and English. Confiscated under John Lackland, it was again ceded by Louis IX. In 1370 the Black Prince took it by assault, and gave it up to fire and sword, — a disaster from which it was slow to recover. The religious wars, pestilence, and famine desolated it in turn, but the ravages of all these were surpassed by the plague of 1630-31, which carried off more than twenty thousand persons. The wise administrations of Henri d'Aguesseau, father of the chancellor, and of Turgot enabled Limoges to recover its former prosperity. There have been several noteworthy conflagrations, destroying whole quarters of the city, built, as it then was, of wood. That of 1790 lasted for two months, and destroyed one hundred and ninety-nine houses; that of 1861 laid under ashes an area of 10,000 square metres. Limoges celebrates every seven years a curious religious festival (*Fête d'Ostension*), during which the relics of St Martial are exposed for seven weeks, attracting large numbers of visitors. It dates from the 10th century, and commemorates a pestilential desolations, which, after destroying forty thousand persons, is believed to have been stayed by the intercession of the saint.

LINACRE, or LYNAKER, THOMAS (1460-1521), a distinguished humanist and physician, was born at Canterbury about the year 1460. Of his parentage or descent nothing certain is known. He received his early education at the cathedral school of Canterbury, then under the direction of William of Selling, afterwards prior of Canterbury. Selling was an ardent scholar, and one of the earliest in England who cultivated Greek learning. From him Linacre must have received his first incentive to this study, in which he afterwards became eminent. Linacre entered the university of Oxford about the year 1480, and in 1484 was elected a fellow of All Souls' College. Shortly afterwards he visited Italy in the train of William of Selling, who was sent by Henry VIII. as an envoy to the papal court, and accompanied his patron as far as Bologna. There he became the pupil of Angelo Poliziano, and afterwards shared the instruction which that great scholar imparted at Florence to the youthful sons of Lorenzo de' Medici. The younger of these princes became Pope Leo X., and was in after years mindful of his old companionship with Linacre.

Among his other teachers and friends in Italy should be mentioned Demetrius Chaleondylas, Hermolaus Barbarus, Aldus Romanus the printer of Venice, and Nicolaus Leonicensis of Vicenza. Linacre took the degree of doctor of medicine with great distinction at Padua. On his return to Oxford, full of the learning and imbued with the spirit of the Italian Renaissance, he formed one of the brilliant circle of Oxford scholars, including Colet, Grocyn, and William Latimer, who are mentioned with so much warm eulogy in the letters of Erasmus.

Linacre does not appear to have practised or taught medicine in Oxford. About the year 1501 he was called to court as tutor of the young prince Arthur; and continued to act in this capacity till the prince's death in 1503. On the accession of Henry VIII. he was appointed the king's physician, an office at that time of considerable influence and importance, and practised medicine in London, having among his patients most of the great statesmen and nobles of the time, as Wolsey, Warham, and Fox.

After some years of professional activity, and when in advanced life, Linacre received priest's orders. But, as he had for some years previously held several clerical benefices, it would seem that he must have been already a deacon, and thus nominally at least a cleric, but this status would not in those days have interfered with his practising as a physician. There is no doubt, however, that his ordination as priest was connected with his retirement from active life. Literary labours, and the cares of the foundation which owed its existence chiefly to him, the Royal College of Physicians, occupied Linacre's remaining years till his death in 1524.

Linacre was more of a scholar than a man of letters, and rather a man of learning than a scientific investigator. It is difficult now to judge of his practical skill in his profession, but it was evidently highly esteemed in his own day; and several instances are recorded of his wise prognosis and judicious treatment. He took no part in political or theological questions, and died too soon to have to declare himself on either side in the formidable controversies which were even in his lifetime beginning to arise.

But his career as a scholar was one eminently characteristic of the critical period in the history of learning through which he lived. He was one of the first Englishmen who studied Greek in Italy, whence he brought back to his native country and his own university the lessons of the "New Learning." His teachers, who have already been named, were some of the greatest scholars of the day. Among his pupils was one—Erasmus—whose name alone would suffice to preserve the memory of his instructor in Greek, and others of note in letters and politics, such as Sir Thomas More, the lamented Prince Arthur, and Queen Mary. Colet, Grocyn, William Lilye, and other eminent scholars were his intimate friends, and he was esteemed by a still wider circle of literary correspondents in all parts of Europe.

Linacre's literary activity was displayed in two directions, in pure scholarship and in translation from the Greek. In the domain of scholarship he was known by the rudiments of (Latin) grammar composed in English for the use of the Princess Mary, and afterwards translated into Latin by George Buchanan, and by a work on Latin composition, *De emendata structura Latini sermonis*, which enjoyed a wide popularity. It was originally composed for the use of St Paul's school, when founded by Dean Colet, but was set aside as unsuited for the purpose. It was, however, printed in London, in 1524, and many times reprinted on the Continent.

Linacre's only medical works were his translations. It was the cherished project of his life to make the works of Galen (and indeed those of Aristotle also) accessible to all readers of Latin. What he effected in the case of the first, though not trifling in itself, is inconsiderable as compared with the whole mass of Galen's writings; and of his translations from Aristotle, some of which are known to have been completed, nothing has survived. The following are the works of Galen translated by Linacre:—(1) *De Similitudine Tumorum*, printed at Paris in 1517; (2) *Methodus Medendi*, Paris, 1519; (3) *De Temperamentis et de Inaequali Intemperie*, Cambridge, 1521; (4) *De Naturalibus Facultatibus*, London, 1523; (5) *De Symptomatum Differentiis et Causis*, London, 1524; (6) *De Pulsuum Usu*, London, without date. He also translated for the use of his pupil Prince Arthur an astronomical treatise of Proclus, *De Sphaera*, which was printed at Venice by Aldus in 1499. The accuracy of these translations and their elegance of style were universally admitted. They have been generally accepted as the standard versions of those parts of Galen's writings, and frequently reprinted, either as a part of the collected works or separately.

But the most important service which Linacre conferred upon his own profession and science was not by his writings. To him was chiefly owing the foundation by royal charter of the College of Physicians in London, which first gave the medical profession in this country a recognized legal status, and which has been the model of all the similar colleges of physicians and surgeons in the three kingdoms. He was the first president of the new college, which he further aided by conveying to it his own house, and by the gift of his library. Shortly before his death Linacre obtained from the King letters patent for the establishment of readerships in medicine at Oxford and Cambridge, and placed some valuable estates in the hands of trustees for their endowment. Two readerships were founded in Merton College, Oxford, and one in St John's College, Cambridge, but owing to neglect and bad management of the funds, they fell into uselessness and obscurity. The Oxford foundation was revived by the university commissioners in 1856 in the form of the Linacre professorship of anatomy. Posterity has done justice to the generosity and public spirit which prompted these foundations; and it is impossible not to recognize a strong constructive genius in the scheme of the College of Physicians, by which Linacre not only first organized the medical profession in England, but impressed upon it for some centuries the stamp of his own individuality. The intellectual fastidiousness of Linacre, and his habits of minute accuracy were, as Erasmus suggests, the chief cause why he accomplished so little and left behind no more permanent literary memorials. It will be found, perhaps, difficult to justify by any extant work the extremely high

reputation which he enjoyed among the scholars of his time. His Latin style was so much admired that, according to the flattering eulogium of Erasmus, Galen spoke better Latin in the version of Linares than he had before spoken Greek; and even Aristotle displayed a grace which he hardly attained to in his native tongue. Erasmus praises also Linares's critical judgment (*vir non exacti tantum sed severi judicii*). According to others it was hard to say whether he were more distinguished as a grammarian or a rhetorician. Of Greek he was regarded as a consummate master; and he was equally eminent as a "philosopher," that is, as learned in the works of the ancient philosophers and naturalists. In this there may have been, as the custom of the day was, some exaggeration; but all have acknowledged the elevation of Linares's character, and the fine moral qualities summed up in the epitaph written by John Caius:—"Fraudes doloque mire perosus; fidus amicis; omnibus ordinibus juxta carus."

The materials for Linares's biography are to a large extent contained in the older biographical collections of George Lilly (in *Paulus Jovius, Descriptio Britannia*), Bale, Ieland, and Pits, in Wood's *Athenae Oxonienses*, and in the *Biographia Britannica*; but all are completely collected in the *Life of Thomas Linares*, by Dr Noble Johnson, London, 1835. Reference may also be made to Dr Munk's *Roll of the Royal College of Physicians*, 2d ed., London, 1878; and the Introduction, by Dr Payne, to a facsimile reproduction of Linares's version of *Galen, de Temperamentis*, published by Messrs. Macmillan, Cambridge, 1881. With the exception of this treatise, none of Linares's works, or to which allusions have been reprinted in modern times.

(J. F. P.)

**LINARES**, an important mining town in the province of Jaen, Spain, is situated in an arid plain, near the foot of the Sierra Morena, 24 miles north-north-east from the town of Jaen, 12 north-east from that of Baeza, and half an hour by rail from the Vadollano station of the Madrid and Cordova line. The streets are ill paved, irregular, and ugly, and, apart from a fine fountain of Roman origin, the town presents no architectural features of interest. There is some trade in the oil and wine of the neighbourhood, which are excellent and plentiful; wool is exported to Catalonia and Valencia; and cattle-breeding, especially of animals for the bull-ring, is also carried on. But the population, which in 1877 numbered 36,630, and includes some 120 English, with a consul and a chaplain, is chiefly engaged in the working of the extensive lead-mines to the north-west of the town, and in various concomitant industries, such as the manufacture of gunpowder, dynamite, match for blasting purposes, rope, and the like. The mining plant is entirely imported, principally from England. In respect of the quantity and uniform excellence of their productions the lead-mines of the province of Jaen are unsurpassed. For the year 1876-77 the joint output of those of Linares, Vileches, Bailon, Carboneros, Santa Helena, and (in part) La Carolina was stated at 1,620,000 cwts. of ore, worth upwards of £800,000,—the proportion of silver to lead varying from 20 to 60 grammes of the former to every 50 kilogrammes of the latter. The best class of ore is exported, chiefly to France and Belgium; the inferior classes are smelted for the most part in Spain. About 2 miles to the south of Linares is the village of Cazlona, which still shows some remains of the ancient Castulo; and the ancient mines some 5 miles to the north, which are now known as "Los Pozos de Anibal," may with some probability be assigned to the Carthaginian period.

**LINCOLN**, one of the four eastern maritime counties of England, lies between 52° 39' and 53° 43' N. lat., and 0° 22' E. and 0° 56' W. long. It is bounded on the N. by the Humber, E. by the German Ocean and the Wash, S.E. for 3 miles by Norfolk, S. by Cambridge and Northampton, S.W. by Rutland, W. by Leicestershire and Notts, and N.W. by Yorkshire. Its greatest length north and south, from Barton-on-Humber to Market Deeping, is 75 miles, its greatest breadth, from Wroot on the west to Saltfleet on the east, is 50 miles, its circuit about 260 miles. Its area is 1,767,962 acres, or about 2762 square miles, making it the second largest county in England.

**Coast-Line.**—The coast-line, about 110 miles in length, is low and marshy; and artificial banks for guarding against the inroads of the sea are to be found, in places, all along the coast. From Grimsby to Skegness traces of a sub-

marine forest are visible; but while the sea is encroaching upon some parts of the coast it is receding from others, as shown by Holbeach, which is now 6 miles from the sea. Several thousand acres have been reclaimed from this part of the Wash, and round the mouth of the Nene on the south-east. The deep bay between the coasts of Lincolnshire and Norfolk, called the Wash, is full of dangerous sandbanks and silt; the navigable portion, off the Lincolnshire coast, is known as the Boston deeps. The rapidity of the tides in this inlet, and the lowness of its shores, which are generally indistinct on account of mist from a moderate offing, render this the most difficult portion of the navigation of the east coast of England.

**Surface and Geology.** The surface of Lincolnshire is generally a large plain, some portions of which are below the level of the sea. The south-east parts are perfectly flat; and about one-third of the county consists of fens and marshes, intersected in all directions by artificial drains, called locally dykes, delphs, drains, becks, leams, and caux. This flat surface is, however, broken by two ranges of calcareous hills running north and south through the county, and known as the Cliff and the Wolds. The former range, on the west, runs nearly due north from Grantham to Lincoln, and thence to the Humber, traversing the Heaths of Lincolnshire, which were formerly open moors, rabbit warrens, and sheep walks, but are now enclosed and brought into high cultivation. Parallel with this range on the east side of it runs the old Roman Emine Street, sometimes called the Cliff Row Road. The Wolds form a ridge of bold hills extending from Spilsby to Barton-on-Humber for about 40 miles, with an average breadth of about 8 miles. Between the Wolds and the sea lie the Marshes, a level tract of rich alluvial soil extending from Barton-on-Humber to Wainfleet, varying in breadth from 5 to 10 miles. Between the Welland and the Nene in the south-east of the county are Gedney Marsh, Holbeach Marsh, Moulton Marsh, and Sutton Marsh.

The Fens, the soil of which has been formed partly by tidal action and partly by the decay of forests, occupy the Isle of Axholme on the north-west, the whole of Ancholme on the north, and most of the country south-east of Lincoln. The chief of these are the Holland, Wildmore, West, and East Fens draining into the Witham, and the Deeping, Bourn, Great Oursand, and Whaplode Fens draining into the Welland. Owing to the dead level of these districts there is perhaps more artificial drainage in Lincolnshire than in any other English county; and this part of the country resembles in many respects, especially in embankments and dykes, the continental Holland.

The drainage of the Fens appears to have early occupied attention. Shortly after the Norman Conquest Richard de Rulos, lord of Brunn, and chamberlain to William I., enclosed and drained a large part of Deeping Fen in so complete a manner that the work would not be discredited by a comparison with the more scientific efforts of modern times. Enclosing the Welland by a bank, he changed "deep dykes" and impassable fens into most fruitful fields and pastures, and the most humid and moorish parts thereof into a garden of pleasure.

The drainage of the remaining levels of Lincolnshire was chiefly commenced in the reigns of James I. and Charles I. The East, West, and Wildmore Fens were contracted for in the 7th Charles I. The earl of Lindsey undertook all the fens in Holland and Kesteven, north of the river Glen up to Lincoln, on the completion of which 21,000 acres were awarded to him. In the 13th of the same reign, the king declared himself the "Undertaker" of the Holland Fen, containing 22,000 acres, out of which he was to have 1000 for his share. Sir John Mounson with other freeholders drained the Ancholme level in the north, and had 5827 acres assigned to them. In the same reign the Isle of Axholme was undertaken by Cornelius Vermuyden and his Dutch and Flemish followers. The operations were interrupted during the civil wars, and many of the works destroyed by the "stilt walkers," so curiously denominated Camden. Little was done towards restoring the works thus destroyed till the middle of the 18th century, when several townships, having a right of common over particular fens, began to join in procuring Acts of

Parliament for their drainage, enclosure, and division. The Holland Fen was the first to be dealt with, about 1764; in spite of renewed and riotous opposition from the "stilt-walkers," all the fen lands were successfully drained and enclosed, and on the completion of the East, West, and Wildmore Fens (about 60,000 acres) the race of "stilt-walkers" became extinct. The low lands adjoining the tidal reaches of the Trent and Humber, and part of those around the Wash, have been raised above the natural level, and enriched by the process of warping, which consists in letting the tide run over the land, and retaining it there a sufficient time to permit of the deposit of the sand and mud held in solution by the waters.

The general appearance of the county is very pleasing. The level tracts are richly cultivated; the hills and dales are interspersed with wood and lawn; and many spots on the Cliff or Wolds command extensive and charming views. The charms of the Fen districts are described as "a beauty as of the sea, of boundless expanse and freedom" (Kingsley). Not a few passages in the writings of Tennyson (a native of the county) bear the impress of the scenery and colourings of the Fens.

The geological formations, for the most part, extend in parallel belts, nearly in the line of the length of the county, from north to south, and succeed one another, in ascending order, from west to east.

1. The lowest is the *Triassic* or *New Red Sandstone* found in the Isle of Axholme and the valley of the Trent in the form of marls, sandstone, and gypsum. The presence of the peroxide of iron which tinges the beds red seems to have been prejudicial to animal life, therefore few fossils are found. Fish scales and teeth, with bones and footprints of the *Lam. rhodina*, are to be met with in the sandstone. The red clay is frequently dug for brick-making. The beds dip gently towards the east. At the junction between the Triassic and Liassic series of beds termed *Blue lias*, which seem to mark a transition from one to the other. These beds are in part exposed in pits near Newark, and extend north by Gainsborough to where the Trent flows into the Humber, passing thence into Yorkshire. The characteristic shells are found at Lea, 2 miles south of Gainsborough, with a thin stratum of bone bed full of fish teeth and scales.

2. The *Lower Liass* comes next in order, with a valuable bed of ironstone now largely worked. This bed is about 27 feet in thickness, and crops out at S.undhorpe, where the workings are open and shallow. The *Middle Liass*, which enters the county near Woolsthorpe, is about 20 or 30 feet thick, and is very variable both in thickness and mineralogical character. The *Upper Liass* enters the county at Stamford, passing by Grantham and Lincoln. It forms the west slope of the Chalk range, and is thickest upon the highest hills. The Liass thus occupies a band about 8 or 10 miles in width in the south, narrowing until on the Humber it is about a mile wide.

3. To this succeed the *Three Oolite* formations. The *Lower Oolite*, somewhat narrower than the Liass, extends from the boundary with Rutland due north past Lincoln to the vicinity of the Humber. The *Middle Oolite*, very narrow in the southern Wiltshire, widening gradually about Stamford, and then suddenly contracting again south of Lincoln, forms a narrow band south-east towards Spalding. It then proceeds north from Lincoln with decreasing width to the vicinity of the Humber. The *Upper Oolite* and Kimmeridge clay start from the vicinity of Stamford, and after attaining their greatest width near Horncastle, run north-north-west to the Humber.

4. In the *Cretaceous* system of the Wolds, the Lower Greensand runs nearly parallel with the Upper Oolite past South Willingham to the Humber. The Upper Greensand and Gault run north-west from Litch, widening eastwards to Kelstern on the east, and cross the Humber. The Chalk formation, about equal in breadth to the three preceding, extends from Bugh across the Humber.

The *Wolds* occupy all its south-east portion between the Middle Oolite belt and the chalk, all its north-east portion between the Greensand and the chalk, and a narrow tract up the course of the *Wolds* river, consists of alluvial deposits or of reformed *Wolds*.

**Minerals.**—Gypsum is dug in the Isle of Axholme, whiting is made from the chalk near the shores of the Humber, and lime is made on the Wolds. Freestone is quarried around Airedale, and good oolite building stone is quarried near Lincoln and other places. Ironstone is found and worked at Claxby near Caistor, and carried into Yorkshire to be smelted; it is also worked at Frodingham, 3 miles north-north-west of Brigg.

**Rivers.**—The Humber separates Lincolnshire from Yorkshire. Its ports on the Lincolnshire side are Barton, New

Holland, and Grimsby. The Trent divides the Isle of Axholme from Lindsey, and falls into the Humber about 30 miles below Gainsborough. Like the Severn, it is noted for a tidal phenomenon called the "eager" or bore, which, at spring tides, rises to the height of from 6 to 8 feet. The Witham rises on the south-west border of the county, flows north past Grantham to Lincoln, and thence east and south-east to Boston, after a course of about 80 miles. This river was once noted for its pike. The Welland rises in north-west Northamptonshire, enters the county at Stamford, and, after receiving the Glen, flows through an artificial channel into the Fossdyke Wash. The Nene on the south-east has but a small portion of its course in Lincolnshire; it flows due north through an artificial outfall called the Wisbech Cut.

**Canals.**—The principal canals are—the Stainforth and Keadby, connecting the Trent with the Yorkshire coal-field; the Louth Navigation, from Louth to Tetney Haven; the Sleaford Navigation, connecting Sleaford with the Witham; and the Grantham Canal, from that town to the Trent at Nottingham. The remainder are chiefly small rivers artificially deepened and embanked.

**Climate.**—The climate of the higher grounds is now noted for its salubrity, and meteorological observation does not justify the reputation for cold and damp often given to the county as a whole. The mean annual temperature of the Fens as given by ten years' observation (1864-73) is 47.9, 1.6 below that of Greenwich. The rainfall of the Fen district is very small as compared with other parts of England. While the average of the whole country was little over 30 inches, at Boston the average fall from 1830 to 1849 was 23.58 inches, and from 1850 to 1869 22.08. At Wisbech south-west winds prevail on an average six months in the year, and north-east winds barely two months.

**Soil and Agriculture.**—The soils vary considerably, according to the geological formations; ten or twelve different kinds may be found in going across the country from east to west. A good sandy loam is common in the Heath division; a sandy loam with chalk, or a flinty loam on chalk marl, abounds on portions of the Wolds; an argillaceous sand, merging into rich loam, lies on other portions of the Wolds; a black loam and a rich vegetable mould cover most of the Isle of Axholme on the north-west; a well-reclaimed marine marsh, a rich brown loam, and a stiff cold clay variously occupy the low tracts along the Humber, and between the north Wolds and the sea; a peat earth, a deep sandy loam, and a rich soapy blue clay occupy most of the east and south Fens; and an artificial soil, obtained by "warping," occupies considerable low strips of land along the tidal reaches of the rivers. The wide grazing lands of Lincolnshire have long been famous, and the arable lands are specially adapted for the growth of wheat and beans. There is no generally recognized rotation of crops. The cattle raised are the Shorthorns and improved Lincolnshire breeds. The dairy, except in the vicinity of large towns, receives little attention. The sheep are chiefly of the Lincolnshire and large Leicestershire breeds, and go to the markets of Yorkshire and the metropolis. Lincolnshire has long been famous for a fine breed of horses both for the saddle and draught. Horse fairs are held every year at Horncastle and Lincoln. Large flocks of geese were formerly kept in the Fens, but their number has been diminished since the drainage of these parts. Where a large number of them were bred, nests were constructed for them one above another; they were daily taken down by the gooseherd, driven to the water, and then reinstated in their nests, without a single bird being misplaced. Decoys were once numerous in the undrained state of the Fens.

The following table gives a classification of holdings according to size as returned on the 25th June 1875 and the 11th June 1880.

*His present Topog.*, p. 11. It is highly probable that the territory now forming Lincolnshire was first settled by a tribe of the Belgæ, who, however, at the time of the invasion by Cæsar, had become a mixed race with the real Britons. This territory was included by Cæsar's first division, and even after the reduction of Britain by Claudius the Fenland remained intact. The county was conquered about 70 A.D., and formed part of the province of Flavia Caesariensis. The tribes which occupied Lincolnshire, according to Ptolemy, were the Goutini, who had Lindum and Ræce (Leicester) for their towns. The date of the introduction of Christianity is uncertain, but we learn from Bede (*Hist. Eccl.*, i. 16) that Adelphus of Colonia Londunensium, which has been mistaken for London, attended the council of Arles (314). Under the Saxon kingdom of Mercia, Lindsey, which probably extended nearly or quite over the modern county of Lincoln, appears to have been a dependent state. Under Edwin of Northumbria, the conqueror of Mercia, Christianity was reintroduced by Paulinus of

York, and Bece tells us that Blæcca, the governor of Lincoln, was, with his household, among the first converts (628).

Early in 870 the Danes or Northmen landed at Humberstone near Grimsby, and ravaged Lindsey and the famous monastery of Bardney on the Witham. Lincolnshire passed permanently into the hands of the Danes about 877, and was included within the boundary of the "Danelage" of Danish jurisdiction as settled by the treaty of 878. Probably the greatest changes consequent upon the Danish invasion are, first, the supplanting of the Anglo-Saxon names of places by those of the Danish termination ending in *by*, which are numerous, and the substitution of the wapentake for the earlier division of the hundred: the ancient British laws and those of the Danes were otherwise not dissimilar. In time the two populations became amalgamated and came under the dominion of the Anglo-Saxon crown. The subsequent history of the county under the Normans is associated more or less with the city of Lincoln. In the civil war between Stephen and the empress Matilda a battle was fought near Lincoln in 1141. In 1171 the Isle of Axholme was the scene of the struggle between Roger de Mowbray, one of the adherents of Prince Henry, and the forces sent against him by his father Henry II. The issue was decided by the Lincolnshire men in favour of the king. In 1216 occurred King John's march across the county, when he lost all his baggage and jewels in the Fosslyke Wash on his way to Swineshead Abbey. In the reign of Edward IV. Sir Robert Wells, at the head of 30,000 Lincolnshire men, was defeated at Losecoat Field near Stamford, March 1470. At the suppression of the monasteries a rebellion broke out at Louth headed by Makerel, the last prior of the abbey of Baulings Oxney, October 1536. The prior was hanged, and the shire for the trouble it gave to King Henry VIII. was designated in a state paper as "one of the most brute and bestial of the whole realm." During the civil wars the county was a scene of numerous contests, the most famous of which was the battle at Grantham in 1643, won by Cromwell over the royalists. The advantage that was taken by the Femmen to destroy the efforts made to drain and enclose the remaining levels of Lincolnshire during this stormy period has been already noticed. Riots broke out at intervals, and were continued down to the middle of the 18th century.

Remains of British camps are found at Barrow, Folkingham, Ingoldby, Ryegby, and Well. Traces of Roman camps are found at Alkborough, Caistor, Gainsborough, Geddely Hill near Holbeach, Honington near Grantham, South Ormsby, and Yarborough. The Roman walls are nearly perfect,—Emme Street, on the east side of the Cliff hills, and the Fossway running south-west from Lincoln. The crown of these remains is without doubt the famous Roman arch called the Newport Gate at Lincoln. Tesselated pavements have been found at Denton, Horkstow, Lincoln, Scampton, and Winterton. Coins of the emperors Nero, Vespasian, and Julian have been found at Lincoln and Ancaster, and two Roman altars to the west of Stow.

There are remains of feudal castles at Boston, Lincoln, Skeford, Somerton, Tattershall, and Torksey. The seats worthy of note (chiefly modern) are Appleby Hall, Aswarby Hall, Belton House, Blankney Hall, Brocksby, Bulby House, Burghley House near Stamford, Burton Hall, Casewick House, Denton Hall, Easton Hall, Hacketon Hall, Haveringham Priory, Lea Hall, Loddington House, Marby Hall, Noston House, Noston Hall, Normanby Hall, Norton Place, Panton Hall, Riby Grove, Somerby Park, Stourton, Syston Park, Thoresby House, Thurlby Hall, Uffington, and Willingham by Stow.

At the time of the suppression of the monasteries in the reign of Henry VIII. there were upwards of one hundred religious houses; and among the Pens rose some of the finest abbeys held by the Benedictines. The Gilbertines were a purely English order which took its rise in Lincolnshire, the canons following the Austin rule, the nuns and lay brothers that of the Cisterians. They generally lived in separate houses, but formed a community having a common church in which the sexes were divided by a longitudinal wall. These houses were at Alvingham, Catby, Holland Briggs, Lincoln, before the gate of which was erected the first Eleanor Cross, Newstead in Louth, Sumpthorpe, the last house of the order, founded by St Gilbert of Gant in 1139, Stamford (a college for students), and Welby. There were nunneries of the order at Havertham, Nun Ormsby, and Tunstall.

The following are a few of the most famous abbeys. (1) Baulings Oxney (Pensioner's), founded 1154, for fourteen canons. The tower, decorated, with arched piers and windows, and the east wall of the south wing remain. (2) The Benedictine Mittle Abbey of Crowland, founded 716, refounded in 948. The foundations of the new church in 1114 were laid on massive piles of oak. Part of the west front was repaired in 1255-81, with beautiful Early English sculpture of the *Legend of St Guthlac* and saints; this, with the Perpendicular north-west tower, 1469-70, remain. (3) Swineshead Abbey (Carthusian), colonized from Furness in 1134 by eleven monks. (4) Thornton-upon-Humber Abbey (Black Canons), founded in 1139. There remain a fragment of the

south wing of the transept, two sides of the decagonal chapter-house (1282), and the beautiful west gate-house, Early Perpendicular (1332-88), with an oriel window on the east.

The general beauty of the parish churches of Lincolnshire is proverbial, but it is incorrect to suppose that they are equally good in every part of the county. In the Parts of Lindsey, though there are some of considerable beauty and interest, the churches can scarcely be considered above the average; several though small and mean present curious early features, particularly the well-known tower of St Peter, Barton-on-Humber, supposed to be of the Saxon period, and those of Crowle, Heapham, and Stow. Those of Grimsby and Wainfleet are cruciform.

In the Parts of Kesteven the churches are not only elegant but well finished, built of excellent stone which abounds at Ancaster and near Skeaford. The church of St Andrew Heckington is the best example of Middle Pointed architecture in the county; it is famed for its Easter sepulchre and fine sedilia. The largest and finest church in this division is doubtless that of St Wolfran at Grantham, 200 by 87 feet, with three collateral naves, and steeple, 271 feet high, of the 14th century.

It is principally in the Parts of Holland that we are to look for the finest churches in the county; they are not to be equalled by those of any other district in the kingdom, which is the more remarkable as the district is comprised wholly of marsh land, and is without stone of any kind. It is highly probable that the churches of the south part of this district owe their origin to the munificence of the abbots of Crowland and Spalding. The earliest specimen of Norman architecture is that of Long Sutton, which has been called the counterpart of Christ Church, Oxford. St Mary and Nicholas at Spalding, 157 feet by 95, has the uncommon feature of a double aisle on each side of the nave, as well as a transept. The glory of the division of Holland is beyond question the church of St Botolph, Boston.

LINCOLN, the capital of the county of that name, is a city and county in itself, and is also a municipal and parliamentary borough. It is picturesquely situated on the summit and south slope of the limestone ridge of the Cliff range of hills which rises from the north bank of the river Witham, at its confluence with the Foss Dyke, to an altitude of 200 feet above the river. It is 132 miles north-west from London by road, and 138 miles by rail.

Plan of Lincoln.

Lincoln is one of the most ancient and interesting cities in England. The ancient British town occupied the crown of the hill beyond the Newport or North Gate. The Roman town consisted of two parallelograms of unequal length, the first extending west from the Newport gate to a point

a little west of the castle keep. The second parallelogram extended due south from this point down the hill towards the Witham as far as Newland, and thence in a direction due east as far as Broad Street. Returning thence due north, it joined the south-east corner of the first and oldest parallelogram in what was afterwards known as the Minster yard, and terminated its east side upon its junction with the north wall in a line with the Newport gate. This is the oldest part of the town, and is named "above hill." After the departure of the Romans, the city walls were extended still further in a south direction across the Witham as far as the great bar gate, the south entrance to the High Street of the city; the junction of these walls with the later Roman one was effected immediately behind Broad Street. These three divisions comprise the boundaries of the municipal and parliamentary boroughs, which are continuous. The "above hill" portion of the city is not well built, but consists of narrow irregular streets, some of which are too steep to admit of being ascended by carriages. The south portion, which is named "below hill," is much more commodious, and contains the principal shops and inns, with many elegant buildings and private residences. Here also are the Great Northern and Midland Railway stations.

The glory of Lincoln is its noble minster. As a study to the architect and antiquary this stands unrivalled, not only as the earliest purely Gothic building in Europe, but as containing within its compass every variety of style from the simple massive Norman of the west front, to the Late Decorated of the east portion. The building material is the oolite and calcareous stone of Lincoln Heath and Haydon, which has the peculiarity of becoming hardened on the surface when tooled. In former days the cathedral had three spires, all of wood or leaded timber. The spire on the central tower was blown down in 1547. Those on the two western towers, 101 feet high, were removed in 1808; good representations of them will be found in the well-known views by Hollar and Buck. The ground plan of the first church, adopted from that of Rouen, was laid by Bishop Remigius in 1086, and the church was consecrated four days after his death, May 6, 1092; the central west front and the font are of this period. The approximate dates of the remaining portions of the fabric may be assigned as follows:—the three west portals and the Norman portion of the west towers above the screen to the top of the third story, about 1148; the nave, its aisles, and the north and south chapels of the west end, completed 1220; the Early English portion of the west front, and the upper parts of the north and south wings, with pinnacle turrets, 1225; the west porch of the main transept, 1220; the crossing, and lower part of the central tower, 1235; the upper part, 1307; the west door of the choir aisles, 1240. The south porch of the presbytery dates 1256. The east window, the finest of its style in England, 57 by 34 feet, dates 1258-88. The choir screens date 1280, the Easter sepulchre 1290. The gables and upper parts of the main transept, the parapets of the south side of the nave, south wing, and west front, and the screen in the south aisle, all date from 1225. The upper parts of the west towers date from 1365; their upper stories, the west windows and parapet of the gulleys porch, and the chapel screens in the transept, 1450. The vaulted lantern of the central tower is 127 feet above the floor. The main transept has two fine rose windows; the one on the north called the Dean's Eye is 30 feet in diameter. The Bishop's Eye to the south is very fine Decorated (c. 1350). The rood screen is mainly c. 1340.<sup>1</sup> The other buildings in

the close that call for notice are the chapter-house of ten sides, 60 feet diameter, 42 feet high, with a fine vestibule of the same height built in 1225, and the library, 104 by 17 feet, which contains a little museum. Among the most famous bishops were St Hugh, who died 1200; Grosseteste, died 1253; Flemming, died 1431, founder of Lincoln College, Oxford; Smith, died 1521, founder of Brasenose, Oxford; Wake; and Gibson. Every stall has produced a prelate or cardinal; among those who have been capitular members may be named Walter Mapes, Henry of Huntingdon, Polydore Vergil, W. Grocyn, W. Outram, George Herbert, S. Pegge, and O. Manning the topographer. Lincoln, the enormous diocese of which in early times extended from the Thames to the Humber, was one of the thirteen cathedrals of the old foundation served by secular canons.

*History.*—The name of Lincoln is a hybrid of Celtic and Latin. It appears in the Ravenna geographer in the form of Lindum Colonia, and in Bede as Lind-colina. Lin-lun is purely Celtic, and exactly describes the early British settlement as the "hill fort by the pool." Lindum Colonia was founded on the site of what is now the castle and cathedral, about 100 A.D. It was besieged by Saxons in 518, and became one of the chief cities of Mercia. After being frequently ravaged by the Danes, Lincoln was recovered by Edmund I. in 1016. Lincoln Castle was built by William I. in 1086, which occasioned the removal of one hundred and sixty-six houses. Great and destructive fires occurred in 1110, 1123, and 1141. King Stephen's siege of the empress Matilda in the castle in 1140. Henry II. was crowned there in the following year, as was King Stephen at Christmas 1147; David, king of Scots, did homage to King John, 1201. Lincoln was captured by King John in 1216, and invested by the barons in 1217. The battle of Lincoln Fair took place in 1218. The city was sacked in 1266. John of Gaunt, earl of Lincoln, married there in 1396 Lady Swinford, Chaucer's sister-in-law; in virtue of his title he held the castle, but built himself a winter house in the lower part of the city. A parliament of Henry VI. met at Lincoln in 1466. The town was stormed by Earl Manchester on behalf of the Parliament in 1644.

*Antiquities.*—One of the most perfect specimens of genuine Roman architecture in England is the Newport or North Gate of Lincoln. It is sunk fully 11 feet below the present level of the street, and has two smaller arches on each side, the one to the west being concealed by an adjoining house. The Roman Emine Street passes through this gate, and runs north of it for 11 or 12 miles as straight as an arrow. Many Roman coins, &c., have been found in the immediate vicinity of the gate. The other gates within the city worthy of notice are the Exchange Gate, a fine specimen of 13th century work, one of the best of the north

leaving upon it a carved representation of the Portgate and Stonebow at the top of High Street is the guildhall. The castle shows traces of Norman foundations of which it consisted of massive beams of wood and grouting. The hall of the old episcopal palace is 90 ft. 1 by 60 wide, and had two rows of grey marble pillars. The modern palace is at Riseholme, 3 miles north of Lincoln. In the cloister garden are preserved a tessellated pavement and the sepulchral slab of a Roman soldier; the splendidly carved stone coffin lid of Bishop Remigius found there has recently been removed into the cathedral. The ancient conduits of St Mary le Wigford, picture square Gothic, and "the Greyfriar's goodly conduit" in the High Street, may also be noticed. The St Mary's Guild near St Peter's at Gowts is a fine specimen of Norman architecture, another fine relic of the domestic architecture of this period is the Jews' House, the mouldings of which are identical with those of the west portals of the cathedral (c. 1148). Near this is Dunsall, where the little Lincoln boy afterwards known as Little St Hugh was crucified by Jews in August 1255. There were formerly three small priories, five friaries, and four hospitals in or near Lincoln. The preponderance of friaries over priories of monks is explained by the fact that the cathedral was served by secular canons. The famous Bishop Grosseteste was the devoted patron of the friars, particularly the Franciscans, who were always in their day the town missionaries.

There were fifty-two churches in the city before the Reformation, all the names of which are preserved. Fourteen remain or have been rebuilt. There are fifteen benefices in the city, consisting of three rectories and twelve vicarages. There are fourteen Nonconformist places of worship.

Sept. 220 x 63 x 74 feet; choir transept, 166 x 44 x 74 feet. Externally the west front is 173 feet broad by 130 feet; the west towers are 206 feet high; the central tower, from which hangs the new Great Tom of Lincoln (5 tons 8 cwts.), is 262 feet high.

<sup>1</sup> The dimensions of the cathedral internally are—nave, 252 x 79'6 x 80 feet; choir, 158 x 82 x 72 feet; angels' choir, which includes presbytery and lady chapel, 166 x 44 x 72 feet; main tran-

Democrat; but four opposition members, of Democratic antecedents, refused to vote for Lincoln, who was yet called a Whig, and by their persistence compelled the election of Trumbull. The Republican party of Illinois was formally organized in 1856; the campaign resulted substantially in a drawn battle, the Democrats gaining a majority in the State for president, while the Republicans elected the governor and State officers. In 1858 the senatorial term of Douglas, author of the repeal of the Missouri compromise, was expiring, and he sought re-election. Lincoln, who had four years before successfully met him in public debate, was now by unanimous resolution of the Republican State convention designated as his rival and opponent. Yielding to the wish of his party friends, Lincoln challenged Douglas to a joint public discussion. The antagonists met in debate at seven designated points in the State, while they also separately addressed audiences in nearly every one of the hundred counties. At the November election the Republicans received a majority in the popular vote, but the Democrats, through a favourable apportionment of representative districts, secured a majority of the legislature, which re-elected Douglas. This remarkable campaign excited the closest attention from every part of the Union. Lincoln, addressing the convention which nominated him, June 16, 1858, opened the discussion with the following bold prophecy:

"A house divided against itself cannot stand. I believe this Government cannot endure permanently half slave and half free. I do not expect the Union to be dissolved—I do not expect the Union to be divided. It will either all fall—but I do expect it will cease to be divided. It will be one thing or all the other. Either the opponents of slavery will arrest the further spread of it, and place it where the public mind shall rest in the belief that it is in course of ultimate extinction; or its advocates will push it forward, till it shall become alike lawful in all the States, old as well as new—North as well as South."

Lincoln's speeches in this campaign won him a national fame, which was greatly increased by several made in Ohio the following year, and especially by his Cooper Institute address in New York city, February 27, 1860. More than any contemporary statesman he had in the long six years' agitation insisted that, transcending the technical point of constitutional authority, or the problem of public policy, the deeper question of human right and wrong lay at the bottom of the slavery controversy.

The Republican national convention, which made "No Extension of Slavery" its principal tenet, met at Chicago, May 16, 1860. Seward was the leading candidate; but the more conservative delegates opposed him as being too radical, and uniting their forces nominated Lincoln, who was elected president of the United States after an unusually animated political campaign, November 6, 1860,<sup>1</sup> and inaugurated at Washington, March 4, 1861. Meanwhile a formidable movement, begun by South Carolina a month before the November election, and based on the slavery agitation, had carried the slave States South Carolina, Georgia, Alabama, Florida, Mississippi, Louisiana, and Texas into secession. A provisional government under the designation "The Confederate States of America," with Jefferson Davis as president, was organized by the seceding States, who seized by force nearly all the forts, arsenals, and public buildings within their limits. Great division of sentiment existed in the North, whether in this emergency acquiescence or coercion was the preferable policy. Lincoln's inaugural address declared the Union perpetual and acts of secession void, and announced the determination of the Government to defend its autho-

ity, and to hold forts and places yet in its possession. On the other hand, he disclaimed any intention to invade, subjugate, or oppress the seceding States. "You can have no conflict," he said, "without being yourselves the aggressors." Fort Sumter in Charleston harbour had been besieged by the secessionists since January; and, it being now on the point of surrender through starvation, Lincoln sent the besiegers official notice on April 8 that a fleet was on its way to carry provisions to the fort, but that he would not attempt to reinforce it unless this effort were resisted. The Confederates, however, immediately ordered its reduction, and after a thirty-four hours' bombardment the garrison capitulated, April 13, 1861.

With civil war thus provoked, Lincoln on April 15th by proclamation called 75,000 three months' militia under arms, and on May 3rd ordered the further enlistment of 61,748 soldiers and 18,000 women for three years' service. He instituted a blockade of the Southern ports, took effective steps to extemporize a navy, convened Congress in special session, and asked for legislation and authority to make the war "short, sharp, and decisive." The country responded with enthusiasm to his summons and suggestions, and the South on its part was not less active. The winter bombardment upon Fort Sumter increased the units of insurrection. Four additional slave States drifted into secession; the Unionists maintained ascendancy in Maryland, Kentucky, and Missouri, and succeeded in dividing Virginia. Minor engagements soon took place between the opposing forces. On July 21, 1861, the first important battle was fought at Bull Run, and resulted in the defeat and panic of the Unionists.

The slavery question presented vexatious difficulties in conducting the war. Acute observers could not fail to note that its gigantic agencies were beginning to work in the direction of practical abolition. Congress in August 1861 passed an Act confiscating rights of slaveowners to slaves employed in hostile service against the Union. On August 31st General Fremont by military order declared martial law and confiscation against active secessionists with freedom to their slaves in the State of Missouri. Believing that under existing conditions such a step was both detrimental to present policy and unauthorized in law, President Lincoln directed him to modify the order to make it conform to the Confiscation Act of Congress. Strong political factions were instantly formed for and against military emancipation, and the Government was sorely beset by antagonistic counsel. The Unionists of the border slave States were greatly alarmed, but Lincoln by his moderate conservatism held them to the military support of the Government. Meanwhile he sagaciously prepared the way for the supreme act of statesmanship which the gathering national crisis already dimly foreshadowed. On March 6, 1862, he sent a special message to Congress recommending the passage of a resolution offering pecuniary aid from the general Government to induce States to adopt gradual abolishment of slavery. Promptly passed by Congress, the resolution produced no immediate result except in its influence on public opinion. A practical step, however, soon followed. In April Congress passed and the president approved an Act emancipating the slaves in the District of Columbia, with compensation to owners—a measure which Lincoln had proposed when in Congress in 1849. Meanwhile slaves of loyal masters were constantly escaping to military camps. Some commanders excluded them altogether; others surrendered them on demand; while still others sheltered and protected them against their owners. Lincoln tolerated this latitude as falling properly within the military discretion pertaining to local army operations. A new case, however, soon demanded his official interference. On the 9th of May 1862 General

<sup>1</sup> The popular vote cast for electors stood:—Lincoln, 1,866,462; Douglas, 1,375,167; Breckinridge, 847,953; Bell, 590,631. The official vote cast by the electors on December 5, 1860, and counted and declared by Congress on February 13, 1861, was:—Lincoln, 180; Breckinridge, 72; Bell, 39; Douglas, 12.

Hunter, commanding in the limited areas gained along the southern coast, issued a short order declaring his department under martial law, and adding—"Slavery and martial law in a free country are altogether incompatible. The persons in these three States—Georgia, Florida, and South Carolina—heretofore held as slaves are, therefore, declared for ever free." As soon as this order, by the slow method of communication by sea, reached the newspapers, Lincoln (May 19) published a proclamation declaring it void; adding further, "Whether it be competent for me as commander-in-chief of the army and navy to declare the slaves of any State or States free, and whether at any time or in any case it shall have become a necessity indispensable to the maintenance of the Government to exercise such supposed power, are questions which under my responsibility I reserve to myself, and which I cannot feel justified in leaving to the decision of commanders in the field. These are totally different questions from those of police regulations in armies or camps." But in the same proclamation Lincoln recalled to the public his own proposal and the assent of Congress to compensate States which would adopt voluntary and gradual abolishment. "To the people of these States now," he added, "I most earnestly appeal. I do not argue. I beseech you to make the argument for yourselves. You cannot, if you would, be blind to the signs of the times." Meanwhile the anti-slavery sentiment of the North constantly increased. During June Congress by express Act prohibited the existence of slavery in all territories outside of States. On July 12th the president called the representatives of the border slave States to the executive mansion, and once more urged upon them his proposal of compensated emancipation. "If the war continues long," he said, "as it must if the object be not sooner attained, the institution in your States will be extinguished by mere friction and abrasion by the mere incidents of the war. It will be gone, and you will have nothing valuable in lieu of it." While Lincoln's appeal brought the border States to no practical decision, it served to prepare public opinion for his final act. During the month of July his own mind reached the virtual determination to give slavery its *coup de grace*, and he wrote and submitted to his cabinet the draft of an emancipation proclamation substantially as afterward issued. Serious military reverses constrained him for the present to withhold it, while on the other hand they served to increase the pressure upon him from anti-slavery men. Horace Greeley having addressed a public letter to him complaining of "the policy you seem to be pursuing with regard to the slaves of the rebels," the president replied August 22, saying, "My paramount object is to save the Union, and not either to save or destroy slavery. If I could save the Union without freeing any slave, I would do it; if I could save it by freeing all the slaves, I would do it; and, if I could do it by freeing some and leaving others alone, I would also do that." Thus still holding back violent reformers with one hand, and leading up halting conservatives with the other, he on September 13 replied among other things to an address from a delegation: "I do not want to issue a document that the whole world will see must necessarily be inoperative like the pope's bull against the comet. . . . I view this matter as a practical war measure, to be decided on according to the advantages or disadvantages it may offer to the suppression of the rebellion. . . . I have not decided against a proclamation of liberty to the slaves, but hold the matter under advisement."

The year 1862 had opened with important Union victories. Grant captured Fort Henry and Donelson, and won the battle of Shiloh. Burnside took possession of Roanoke island on the North Carolina coast. The

famous contest between the new ironclads "Monitor" and "Merrimac" ended in the Confederate vessel being beaten back, crippled, and ultimately destroyed. Farragut with a wooden fleet ran past the twin forts St Philip and Jackson, compelled the surrender of New Orleans, and gained control of the lower Mississippi. These successes extended from January to April. The succeeding three months brought disaster and discouragement to the Union army. McClellan's campaign against Richmond was made abortive by his bad generalship, and compelled the withdrawal of his army. Pope's army, advancing against the same city by another line, was beaten back upon Washington in defeat. The tide of war, however, once more turned in the defeat of Lee's invading army at South Mountain and Antietam in Maryland on the 14th and 17th of September, compelling him to retreat.

With public opinion thus ripened by alternate defeat and victory, President Lincoln on September 22, 1862, issued his preliminary proclamation of emancipation, giving notice that on the 1st of January 1863, "all persons held as slaves within any State or designated part of a State the people whereof shall then be in rebellion against the United States shall be then, thenceforward, and for ever free." In his message to Congress on the 1st of December following, he again urged his plan of gradual, compensated emancipation "as a means, not in exclusion of, but additional to, all others for restoring and preserving the national authority throughout the Union." On the 1st day of January 1863 the final proclamation of emancipation was duly issued, designating the States of Arkansas, Texas, Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina, and certain portions of Louisiana and Virginia, as "this day in rebellion against the United States," and proclaiming that, in virtue of his authority as commander-in-chief, and as a necessary war measure for suppressing rebellion, "I do order and declare that all persons held as slaves within said designated States and parts of States, are and henceforward shall be free," and pledging the executive and military power of the Government to maintain such freedom. The legal validity of these proclamations was never pronounced upon by the national courts; but their decrees gradually enforced by the march of armies were soon recognized by public opinion to be practically irreversible. Such dissatisfaction as they caused in the border slave States died out in the stress of war. The systematic enlistment of negroes and their incorporation into the army by regiments, hitherto only tried as exceptional experiments, were now pushed with vigour, and, being followed by several conspicuous instances of their gallantry on the battlefield, added another strong impulse to the sweeping change of popular sentiment. To put the finality of emancipation beyond all question, Lincoln in the winter session of 1863-64 strongly supported a movement in Congress to abolish slavery by constitutional amendment, but the necessary two-thirds vote of the House could not then be obtained. In his annual message of December 6, 1864, he urged the immediate passage of the measure. Congress now acted promptly: on January 31, 1865, that body by joint resolution proposed to the States the 13th amendment of the federal constitution, providing that "neither slavery nor involuntary servitude, except as a punishment for crime, whereof the party shall have been duly convicted, shall exist within the United States or any place subject to their jurisdiction." Before the end of that year twenty-seven out of the thirty-six States of the Union (being the required three-fourths) had ratified the amendment, and official proclamation made December 18, 1865, declared it duly adopted.

The foreign policy of President Lincoln, while subordinate in importance to the great questions of the civil war,

nevertheless presented several difficult and critical problems for his decision. Towards the close of 1861 the arrest by Captain Wilkes of two Confederate envoys proceeding to Europe in the British steamer "Trent" seriously threatened peace with England. Public opinion in America almost unanimously sustained the act; but Lincoln, convinced that the proceeding had been unlawful, promptly, upon the suggestion of England, ordered the liberation of the prisoners. A still broader foreign question grew out of Mexican affairs, when events culminating in the setting up of Maximilian of Austria as emperor under protection of French troops demanded the constant watchfulness of the United States. Lincoln's course was one of prudent moderation. France voluntarily declared that she sought in Mexico only to satisfy injuries done her and not to overthrow or establish local government or to appropriate territory. The United States Government replied that, relying on these assurances, it would maintain strict non-intervention, at the same time openly avowing the general sympathy of its people with a Mexican republic, and that "their own safety and the cheerful destiny to which they aspire are intimately dependent on the continuance of free republican institutions throughout America." In the early part of 1863 the French Government proposed a mediation between the North and the South. This offer President Lincoln declined to consider, Seward replying for him that it would only be entering into diplomatic discussion with the rebels whether the authority of the Government should be renounced, and the country delivered over to disunion and anarchy.

The civil war gradually grew to dimensions beyond all expectation. By January 1863 the Union armies numbered near a million men, and were kept up to this strength till the end of the struggle. The Federal war debt eventually reached the sum of \$2,700,000,000. The fortunes of battle were somewhat fluctuating during the first half of 1863, but the beginning of July brought the Union forces decisive victories. The reduction of Vicksburg and Port Hudson, with other operations, restored complete control of the Mississippi, severing the Southern Confederacy. In the east Lee had the second time marched his army into Pennsylvania to suffer a disastrous defeat at Gettysburg, on July 1st to 3d, though he was able to withdraw his shattered forces south of the Potomac. At the dedication of this battlefield as a soldiers' cemetery in November, President Lincoln made the following oration, which has taken permanent place as a classic in American literature:—

"Four score and seven years ago our fathers brought forth on this continent a new nation conceived in liberty and dedicated to the proposition that all men are created equal. Now we are engaged in a great civil war testing whether that nation, or any nation so conceived and so dedicated, can long endure. We are met on a great battlefield of that war. We have come to dedicate a portion of that field as a final resting-place for those who here gave their lives that that nation might live. It is altogether fitting and proper that we should do this. But, in a larger sense, we cannot dedicate, we cannot consecrate, we cannot hallow this ground. The brave men, living and dead, who struggled here have consecrated it far above our poor power to add or detract. The world will little note nor long remember what we say here, but it can never forget what they did here. It is for us the living rather to be dedicated here to the unfinished work which they who fought here have thus far so nobly advanced. It is rather for us to be here dedicated to the great task remaining before us—that from these honoured dead we take increased devotion to that cause for which they gave the last full measure of devotion—that we here highly resolve that these dead shall not have died in vain, that this nation under God shall have a new birth of freedom, and that government of the people, by the people, for the people, shall not perish from the earth."

In the unexpected prolongation of the war, volunteer enlistments became too slow to replenish the waste of armies, and in 1863 the Government was forced to resort

to a draft. The enforcement of the conscription created much opposition in various parts of the country, and led to a serious riot in the city of New York on July 13. President Lincoln executed the draft with all possible justice and forbearance, but refused every importunity to postpone it. It was made a special subject of criticism by the Democratic party of the North, which was now organizing itself on the basis of a discontinuance of the war, to endeavour to win the presidential election of the following year. Mr Vallandigham of Ohio, having made a violent public speech against the war and military proceedings, was arrested by General Burnside, tried by military commission, and sentenced to imprisonment; a writ of *habeas corpus* was refused, and the sentence was changed by the president to transportation beyond the military line. By way of political defiance the Democrats of Ohio nominated Vallandigham for governor. Prominent Democrats and a committee of the Convention having appealed for his release, Lincoln wrote two long letters in reply discussing the constitutional question, and declaring that in his judgment the president as commander-in-chief in time of rebellion or invasion holds the power and responsibility of suspending the privilege of the writ of *habeas corpus*, but offering to release Vallandigham if the committee would sign a declaration that rebellion exists, that an army and navy are constitutional means to suppress it, and that each of them would use his personal power and influence to prosecute the war. This liberal offer and their refusal to accept it counteracted all the political capital they hoped to make out of the case; and public opinion was still more powerfully influenced in behalf of the president's action, by the pathos of the query which he propounded in one of his letters:—"Must I shoot the simple-minded soldier boy who deserts, while I must not touch a hair of a wily agitator who induces him to desert?" When the election took place in Ohio, Vallandigham was defeated by a majority of more than a hundred thousand.

Many unfounded rumours of a willingness on the part of the Confederate States to make peace were circulated from time to time to weaken the Union war spirit. To all such suggestions, up to the time of issuing his emancipation proclamation, Lincoln announced his readiness to stop fighting and grant amnesty, whenever they would submit to and maintain the national authority under the constitution of the United States. Certain agents in Canada having in 1864 intimated that they were empowered to treat for peace, Lincoln, through Greeley, tendered them safe conduct to Washington. They were by this forced to confess that they possessed no authority to negotiate. The president thereupon sent them, and made public, the following standing offer:—

"To whom it may concern:—

"Any proposition which embraces the restoration of peace, the integrity of the whole Union, and the abandonment of slavery, and which comes by and with an authority that can control the armies now at war against the United States, will be received and considered by the Executive Government of the United States, and will be met by liberal terms on substantial and collateral points, and the bearer or bearers thereof shall have safe conduct both ways.

"ABRAHAM LINCOLN."

"July 18, 1864."

A noteworthy conference on this question took place near the close of the civil war, when the strength of the rebellion was almost exhausted. F. P. Blair, senior, a personal friend of Jefferson Davis, acting solely on his own responsibility, was permitted to go from Washington to Richmond, where, after a private and unofficial interview, Davis in writing declared his willingness to enter a conference "to secure peace to the two countries." Report being duly made to President Lincoln, he wrote a note consenting to receive any agent sent informally "with

a view of securing peace to the people of our common country." Upon the basis of this latter proposition three Confederate commissioners finally came to Hampton Roads, where President Lincoln and Secretary Seward met them, and on February 3, 1865, an informal conference of four hours' duration was held. Private reports of the interview agree substantially in the statement that the Confederates proposed a cessation of the civil war, and postponement of its issues for future adjustment, while for the present the belligerents should unite in a campaign to expel the French from Mexico, and to enforce the Monroe doctrine. President Lincoln, however, declined the ensnaring alliance, and adhered to the instructions he had given Seward before deciding to personally accompany him. These formulated three indispensable conditions to adjustment:—first, the restoration of the national authority throughout all the States; second, no receding by the executive of the United States on the slavery question; third, no cessation of hostilities short of an end of the war, and the disbanding of all forces hostile to the Government. These terms the commissioners were not authorized to accept, and the interview ended without result.

As Lincoln's first presidential term of four years neared its end, the Democratic party gathered itself for a supreme effort to regain the ascendancy lost in 1860. The slow progress of the war, the severe sacrifice of life in campaign and battle, the enormous accumulation of public debt, arbitrary arrests and suspension of *habeas corpus*, the rigour of the draft, and the proclamation of military emancipation furnished ample subjects of bitter and vindictive campaign oratory. A partisan coterie which surro unded McClellan loudly charged the failure of his Richmond campaign to official interference in his plans. Vallandigham had returned to his home in defiance of his banishment beyond military lines, and was leniently suffered to remain. The aggressive spirit of the party, however, pushed it to a fatal extreme. The Democratic National Convention adopted (August 29, 1864) a resolution declaring the war a failure, and demanding a cessation of hostilities; it nominated McClellan for president, and instead of adjourning *sine die* as usual, remained organized, and subject to be convened at any time and place by the executive national committee. This threatening attitude, in conjunction with alarming indications of a conspiracy to resist the draft, had the effect to thoroughly consolidate the war party, which had on June 8 unanimously renominated Lincoln. At the election held November 8, 1864, Lincoln received 2,216,076 of the popular votes, and McClellan but 1,808,725; while of the presidential electors 212 voted for Lincoln and 21 for McClellan. Lincoln's second term of office began March 4, 1865.

While this political contest was going on the civil war was being brought to a decisive close. Grant, at the head of the army of the Potomac, followed Lee from before Washington to Richmond and Petersburg, and held him in siege to within a few days of final surrender. Sherman, commanding the bulk of the Union forces in the Mississippi valley, swept in a victorious march through the heart of the confederacy to Savannah on the coast, and thence northward to North Carolina. Lee evacuated Richmond April 2, and was overtaken by Grant and compelled to surrender his entire army April 9, 1865. Sherman pushed Johnston to a surrender April 26. This ended the war, the submission of scattering detachments following soon after.

Lincoln being at the time on a visit to the army, entered Richmond the day after its surrender. Returning to Washington, he made his last public address on the evening of April 11, devoted mainly to the question of reconstructing loyal governments in the conquered States. On the

evening of April 14 he attended Ford's theatre in Washington. While seated with his family and friends absorbed in the play, John Wilkes Booth, an actor, who with others had prepared a plot to assassinate the several heads of government, went into the little corridor leading to the upper stage-box, and secured it against ingress by a wooden bar. Then stealthily entering the box, he discharged a pistol at the head of the president from behind, the ball penetrating the brain. Brandishing a huge knife, with which he wounded Colonel Rathbone who attempted to hold him, the assassin rushed through the stage-box to the front and leaped down upon the stage, escaping behind the scenes and from the rear of the building, but was pursued, and twelve days afterwards shot in a barn where he had concealed himself. The wounded president was borne to a house across the street, where he breathed his last at 7 A.M., April 15, 1865.

In 1812 he had married Mary Todd, also of Kentucky, who bore him four children. Only one son, Robert T. Lincoln, survives, who is at this date (1882) secretary of war of the United States.

President Lincoln was of unusual stature, 6 feet 4 inches, and of spare but muscular build; he had been in youth remarkably strong and skilful in the athletic games of the frontier, where, however, his popularity and recognized impartiality oftener made him an umpire than a champion. He had regular and prepossessing features, dark complexion, broad high forehead, prominent cheek bones, grey deep-set eyes, and bushy black hair, turning to grey at the time of his death. Abstemious in his habits, he possessed great physical endurance. He was almost as tender-hearted as a woman. "I have not willingly planted a thorn in any man's bosom," he was able to say. His patience was inexhaustible. He had naturally a most cheerful and sunny temper, was highly social and sympathetic, loved pleasant conversation, wit, anecdote, and laughter. Beneath this, however, ran an undercurrent of sadness; he was occasionally subject to hours of deep silence and introspection that approached a condition of trance. In manner he was simple, direct, void of the least affectation, and entirely free from awkwardness, oddity, or eccentricity. His mental qualities were

a quick analytic perception, strong logical powers, a tenacious memory, a liberal estimate and tolerance of the opinions of others, ready intuition of human nature; and perhaps his most valuable faculty was his ability to divest himself of all feeling or passion in weighing motives of persons or problems of state. His speech and action were plain, terse, forcible. Relating anecdotes with appreciative humour and fascinating dramatic skill, he used them freely and effectively in conversation and argument. He loved manliness, truth, and justice. He despised all trickery and selfish greed. In arguments at the bar he was so fair to his opponent that he frequently appeared to concede away his client's case. He was ever ready to take blame on himself and bestow praise on others. "I claim not to have controlled events," he said, "but confess plainly that events have controlled me." The Declaration of Independence was his political chart and inspiration. He acknowledged a universal equality of human rights. "Certainly the negro is not our equal in colour," he said, "perhaps not in many other respects; still, in the right to put into his mouth the bread that his own hands have earned, he is the equal of every other man white or black." He had unchanging faith in self-government. "The people," he said, "are the rightful masters of both congresses and courts, not to overthrow the constitution, but to overthrow the men who pervert the constitution." Yielding and accommodating in non-essentials, he was inflexibly firm in a principle or position deliberately taken. "Let us have faith that right makes might," he said, "and in that faith let us to the end dare to do our duty as we understand it." The emancipation proclamation once issued, he reiterated his purpose never to retract or modify it. "There have been men base enough," he said, "to propose to me to return to slavery our black warriors of Port Hudson and Olustee, and thus win the respect of the masters they fought. Should I do so, I should deserve to be damned in time and eternity. Come what will, I will keep my faith with friend and foe." Benevolence and forgiveness were the very basis of his character; his world-wide humanity is aptly embodied in a phrase of his second inaugural: "With malice toward none, with charity for all." His nature was deeply religious, but he belonged to no denomination; he had faith in the eternal justice and boundless mercy of Providence, and made the golden rule of Christ his practical creed. History must accord him a rare sagacity in guiding a great people through the perils of a mighty revolution, an admirable singleness of aim, a skilful discernment and courageous seizure of the golden moment to free

his nation from the incubus of slavery, faithful adherence to law and conscientious moderation in the use of power, a shining personal example of honesty and purity, and finally the possession of that subtle and indefinable magnetism by which he subordinated and directed dangerously disturbed and perverted moral and political forces to the restoration of peace and constitutional authority to his country, and the gift of liberty to four millions of human beings. Architect of his own fortunes, rising with every opportunity, mastering every emergency, fulfilling every duty, he not only proved himself pre-eminently the man for the hour, but the signal benefactor of posterity. As statesman, ruler, and liberator civilization will hold his name in perpetual honour.

(J. G. N.)

**LINDAU**, a town in the government district of Swabia and Neuburg, Bavaria, and the central point of the transit trade between that country and Switzerland, is situated on two islands off the north-eastern shore of Lake Constance, in 47° 34' N. lat., 9° 43' E. long. The town is a terminus of the Vorarlberg Railway, and of the Munich Lindau line of the Bavarian State Railway, and is connected with the mainland both by a wooden bridge and by a railway embankment of stone erected in 1853. There are Roman Catholic and Lutheran churches, a royal estate, an old town-hall, classical, commercial, and industrial schools, and also manufactories for surgical and musical instruments, a fishery, and a fine harbour provided with a lighthouse and much visited by steamers from Constance and other places on the lake. Opposite the custom-house is a bronze statue of king Maximilian II., erected in 1856. The trade is chiefly in grain, fruit, wine, cherry brandy, fish, cheese, and lard. In January 1882 the population was about 5350.

On the site which the town now occupies there is believed to have been formerly an ancient Roman camp, *Castra Taberni*. Authentic records of Lindau date back to the end of the 9th century. In 1531 it joined the Smalkald league, and in 1617 was unsuccessfully besieged by the Swedes. From 1275 to 1803 it was a free imperial town. In 1804 it passed to Austria, and in 1805 to Bavaria.

**LINDLEY, JOHN** (1799–1865), botanist, was born on February 5, 1799, at Catton near Norwich, where his father, George Lindley, author of *A Guide to the Orchard and Kitchen Garden*, owned a nursery garden. He was educated at Norwich grammar school, and early manifested a taste for the studies in which he afterwards gained distinction. His first publication, in 1819, a translation of the *Analyse du Fruit* of Richard, was followed in 1820 by an original *Monographia Rosarum*, with descriptions of new species, and drawings executed by himself, and in 1821 by *Monographia Digitalium*, and by "Observations on Pomaceæ" contributed to the *Transactions of the Linnean Society*. Shortly afterwards he went to London, where he was engaged by Loudon to write the descriptive portion of the *Encyclopædia of Plants*. In the course of his labours on this undertaking, which was completed in 1829, and of which the "botanical merits" are in the preface assigned by the editor to Lindley, he became thoroughly convinced of the superiority of the "natural" system of Jussieu, as distinguished from the "artificial" system of Linnaeus followed in the *Encyclopædia*; the conviction found expression in *A Synopsis of British Flora, arranged according to the Natural Order* (1829), and in *An Introduction to the Natural System of Botany* (1830). In 1829 Lindley, who since 1822 had been assistant secretary to the Horticultural Society, was appointed to the chair of botany in University College, London; he lectured also on botany from 1831 at the Royal Institution, and from 1835 at the Botanic Gardens, Chelsea. During his professoriate of more than thirty years he wrote many scientific and popular works, besides contributing largely to the *Botanical Register*, of which he was editor for many years, and to the *Gardener's Chronicle*, in which he had charge of the horticultural department from 1841. He became a fellow of the Royal, Linnean, and Geological Societies, and had

the honour of being admitted to a large number of foreign scientific bodies. He resigned his chair in 1860, and died of apoplexy at Turnham Green on November 1, 1865.

Besides those already mentioned, the works of Lindley include *An Outline of the First Principles of Horticulture* (1832), *An Outline of the Structure and Physiology of Plants* (1832), *A Natural System of Botany* (1833), *The Fossil Flora of Great Britain* (the joint work of Lindley and Hutton, 1841–55), *Flora Medica* (1838), *The Vegetable Kingdom* (1846), *Theory of Horticulture* (2d ed., 1855), *Eden Orchardiana* (1852), *De ciper's Botanic* (1858), *A Lady's Botany, a School Botany*, the volume *Botany* in the Library of Useful Knowledge, and a great of the botanical articles in the *Penny Cyclopædia*. See *BIOGRAPHY*, vol. iv. p. 81.

**LINDSEY, THEOPHILUS** (1723–1808), an English theological writer, was born in Middlewich, Cheshire, on June 20, 1723, was educated at the Leeds Free School, and in 1741 entered St John's College, Cambridge, of which, after graduating with distinction, he became a fellow in 1747. For some time he held a curacy in Spitalfields, London, and from 1751 to 1756 he travelled on the Continent in the capacity of tutor to the young duke of Northumberland. On his return he was presented to the living of Kirkby-Wiske in Yorkshire, and after exchanging it for that of Piddletown in Dorsetshire he in 1763 removed to Catterick in Yorkshire. Meanwhile he had begun to entertain anti-Trinitarian views, and to be troubled in conscience about their inconsistency with the creed he had repeatedly subscribed; since 1769 the intimate friendship of Priestley had served to foster his scruples, and in 1771 he united with Archdeacon Blackburne (his father-in-law), Jebb, Wyvell, and Law in preparing a petition to parliament with the prayer that clergymen of the church, and graduates of the universities, might be relieved from the burden of subscribing to the thirty-nine articles, and restored to their undoubted rights as Protestants of interpreting Scripture for themselves. After two hundred and fifty signatures to the document had, with six months of vast effort on Lindsey's part, been obtained, it was, in February 1772, rejected in the House of Commons by a majority of two hundred and seventeen to seventy-one; the adverse vote was repeated in the following year, and in the end of 1773, seeing no prospect of obtaining within the church the relief which his conscience demanded, Lindsey resigned his vicarage and took leave of a warmly attached congregation. In April 1774 he began to conduct a Unitarian service in a room in Essex Street, Strand, London; four years later he removed to a chapel built for him in the same street. Here he continued to labour till 1793, when he resigned his charge in favour of Disney, who like himself had left the established church, and had become his colleague. His active interest in the Unitarian movement continued, however, until his death, which took place on November 3, 1808.

Lindsey's chief work is *An History and View of the State of the Unitarian Doctrine and Worship from the Reformation to our own Times*, 1781, in it he claims, amongst others, Bunnet, Tillotson, S. Clarke, Hoare, and Sir L. Newton for the Unitarian view. His other publications, mostly of a sermonic kind, include *Apology on Reasoning the Evidence on Calvary* (1771), and *Signs of the Apostasy* (1776); *The Book of Common Prayer referred according to the plan of the late Dr Samuel Clarke*, 1774, *Dissertation on the Prophecy of S. John's Gospel as it appears in our Christ*, 1779, *Unitarian Preaching*, 1788; *Considerations upon Christian Holiness*, 1792; *A Collection of Sermons on the Divine Government, showing that everything is as God will, and for good to all*, 1802. Two volumes of *Sermons, with appropriate prayers annexed*, were published posthumously in 1810, and a volume of *Memoirs*, by Thomas Belsham, appeared in 1812.

**LINEN MANUFACTURES**. Under this term are comprehended all yarns spun and fabrics woven from flax fibre. The cultivation and preparation of the fibre, and its treatment till it reaches the market as a commercial product, are dealt with under **FLAX**, vol. ix. p. 293.

From the earliest periods of human history till almost the close of the 18th century the linen manufacture was

one of the most extensive and widely disseminated of the domestic industries of European countries. The preparation and spinning of yarn gave occupation to women of all classes; and the operations of weaving employed large numbers of both sexes. The industry was most largely developed in Russia, Austria, Germany, Holland, Belgium, the northern provinces of France, and certain parts of England, in the north of Ireland, and throughout Scotland; and in these countries its importance was generally recognized by the enactment of special laws, having for their object the protection and extension of the trade. The inventions of Arkwright, Hargreaves, and Crompton in the later part of the 18th century, benefiting as they did, almost exclusively, the art of cotton spinning, and the unparalleled development of that branch of textile manufactures, largely due to the ingenuity of these inventors, gave the linen trade as it then existed a fatal blow. Domestic spinning, and with it hand-loom weaving, immediately began to shrink; a large and most respectable section of the operative classes in western Europe found their employment dwindling away, and the wages they earned from their diminished labour insufficient to ward off starvation. The trade which had supported whole villages and provinces entirely disappeared, and the linen manufacture, in attenuated dimensions and changed conditions, took refuge in special localities, where it resisted, not unsuccessfully, the further assaults of cotton, and, with varying fortunes, rearranged its relations in the community of textile industries. The linen industries of the United Kingdom were the first to suffer from the aggression of cotton; more slowly the influence of the rival textile travelled across Continental countries; and even to the present day, in Russia, and in other regions remote from great commercial highways, the domestic manufacture of linens holds its place almost as it has done from the earliest period. In 1810 Napoleon I., with a view partly to promote Continental linen industries, and partly to strike a blow at the great British manufacture of cotton, issued a proclamation offering a reward of one million francs to any inventor who should devise the best machinery for the spinning of flax yarn. Within a few weeks thereafter Philippe de Girard patented in France important inventions for flax spinning by both dry and wet methods. His inventions, however, did not receive the promised reward, and were indeed neglected in his native country. In 1815 he was invited by the Austrian Government to establish a spinning mill at Hirtenberg near Vienna, which was run with his machinery for a number of years, but ultimately it failed to prove a commercial success. In the meantime, however, English inventors, stimulated rather than daunted by the success of cotton machinery, had applied themselves to the task of adapting machines to the preparation and spinning of flax. The foundation of machine spinning of flax was laid by John Kendrew and Thomas Porthouse of Darlington, who, in 1787, secured a patent for "a mill or machine upon new principles for spinning yarn from hemp, tow, flax, or wool." These machines, imperfect as they were, attracted much notice, and were introduced in various localities both in England and Scotland into mills fitted specially for flax spinning. By innumerable successive improvements and modifications, the invention of Kendrew and Porthouse developed into the perfect system of machinery with which, at the present day, spinning-mills are furnished; but progress in adapting flax fibres for mechanical spinning, and linen yarn for weaving cloth by power-loom, was much slower than in the corresponding case of cotton.

The implements used in the preparation of linen yarn in ancient and modern times, down to the end of the 18th century, were of the most primitive and inexpensive

description. Till comparatively recent times, the sole spinning implements were the spindle and distaff. The spindle, which is the fundamental apparatus in all spinning machinery, was nothing more or less than a round stick or rod of wood about 12 inches in length, tapering towards each extremity, and having at its upper end a notch or slit into which the yarn might be caught or fixed. In general, a ring or "whorl" of stone or clay was passed round the upper part of the spindle to give it momentum and steadiness when in rotation. The distaff, or rock, was a rather longer and stronger bar or stick, around one end of which, in a loose coil or ball, the fibrous material to be spun was wound. The other extremity of the distaff was carried under the left arm, or fixed in the girdle at the left side, so as to have the coil of flax in a convenient position for drawing out to yarn. A prepared end of yarn being fixed into the notch, the spinster, by a smart rolling motion of the spindle with the right hand against the right leg, threw it out from her, spinning in the air, while, with the left hand, she drew from the rock an additional supply of fibre which was formed into a uniform and equal strand with the right. The yarn being sufficiently twisted was released from the notch, wound around the lower part of the spindle, and again fixed in the notch at the point insufficiently twisted; and so the rotating, twisting, and drawing out operations went on till the spindle was full. So persistent is an ancient and primitive art of this description that to the present day, in remote districts of Scotland,—the country where machine spinning has attained its highest development,—spinning with rock and spindle is yet practised; and, rude as these implements are, yarn of extraordinary delicacy, beauty, and tenacity has been spun by their agency. The first improvement on the primitive spindle was found in the construction of the hand-wheel, in which the spindle, mounted in a frame, was fixed horizontally, and rotated by a band passing round it and a large wheel, set in the same framework. Such a wheel became known in Europe about the middle of the 16th century, but it appears to have been in use for cotton-spinning in the East from time immemorial. At a later date, which cannot be fixed, the treadle motion was attached to the spinning wheel, enabling the spinster to sit at work with both hands free; and the introduction of the two-handed or double-spindle wheel, with flyers or twisting arms on the spindles, completed the series of mechanical improvements effected on flax spinning till the end of the 18th century. The common use of the two-handed wheel throughout the rural districts of Ireland and Scotland is a matter still within the recollection of middle-aged people; but spinning wheels are now seldom seen.

The modern manufacture of linen divides itself into two branches, spinning and weaving, to which may be added the bleaching and various finishing processes, which, in the case of many linen textures, are laborious undertakings and important branches of industry.

Flax, when received into the mills, has to undergo a train of preparatory operations before it arrives at the stage of being twisted into yarn. The whole operations in yarn manufacture comprise (1) heckling, (2) preparing, and (3) spinning.

*Heckling.*—This first preparatory process consists not only in combing out, disentangling, and laying smooth and parallel the separate fibres, but also serves to split up and separate into their ultimate filaments the strands of fibre which, up to this point, have been agglutinated together. The heckling process was, until recent times, done by the hand; and it was one of fundamental importance, requiring the exercise of much dexterity and judgment. The

<sup>1</sup> See Dr Arthur Mitchell's *The Past in the Present*, Edinburgh, 1880.

broken, ravelled, and short fibres, which separate out in the heckling process, form tow, an article of much inferior value to the spinner; and the proportion of tow made in the process of hand-heckling varies according to the skill and knowledge of the heckler. A good deal of hand-heckling is still practised, especially in Irish and Continental factories; and it has not been found practicable, in any case, to entirely dispense with a rough preparation of the fibre by hand labour. In heckling by hand, the heckler stakes a handful or "strick" of rough flax, winds the top end around his hands, and then, spreading out the root end as broad and flat as possible, by a swinging motion dashes the fibre into the teeth or needles of the rougher or "ruffer" heckle. The rougher is a board plated with tin, and studded with spikes or teeth of steel about 7 inches in length, which taper to a fine sharp point. The heckler draws his strick several times through this tool, working gradually up from the roots to near his hand, till in his judgment the fibres at the root end are sufficiently combed out and smoothed. He then seizes the root end and similarly treats the top end of the strick. The stricks, as finished, are carefully piled up in a regular manner, keeping each handful separate for convenience of future treatment. The same process is again repeated on a similar tool, the teeth of which are 5 inches long, and much more closely studded together; and for the finer counts of yarn a third and a fourth heckle may be used, of still increasing fineness and closeness of teeth. In dealing with certain varieties of the fibre, for fine spinning especially, the flax is, after roughing, broken or cut into three lengths—the top, middle, and root ends. Of these the middle cut is most valuable, being uniform in length, strength, and quality. The root end is more woody and harsh, while the top, though fine in quality, is uneven and variable in strength. From some flax of extra length it is possible to take two short middle cuts; and, again, the fibre is occasionally only broken into two cuts according to the judgment and requirement of the manufacturer. Flax so prepared is known as "cut line" in contradistinction to "long line" flax, which is the fibre unbroken. The subsequent treatment of line, whether long or cut, does not present sufficient variation to require further reference to these distinctions.

In the case of heckling by machinery, the flax is first roughed and arranged in stricks, as above described under hand heckling. Considerable variations are presented in the construction of heckling machines, but the general principles of those now most commonly adopted, such as the machines of Combe, of Horner, or of Cotton, &c., are identical. These are known as vertical sheet heckling machines (fig. 1), their essential features being a set of endless leather bands or sheets *f, g* revolving over a pair of rollers *c, h* in a vertical direction. These sheets are crossed by iron bars, to which heckle stocks, furnished with teeth, are screwed. The heckle stocks on each separate sheet are of one size and gauge, but each successive sheet in the length of the machine is furnished with stocks of increasing fineness, so that the heckling tool at the end where the flax is entered is the coarsest, while that to which the fibre is last submitted has the smallest and most closely set teeth. Thus the whole of the endless vertical revolving sheet presents a continuous series of heckle teeth, and the machines are furnished with a double set of such sheets revolving face to face, so close together that the pins of one set of sheets intersect those on the opposite stocks. Overhead, and exactly centred between these revolving sheets, is the head or holder channel *a*, from which the flax hangs down while it is undergoing the heckling process on both sides. The flax is fastened in a holder *b*, consisting of two heavy flat plates of iron, between which it is spread

and tightly screwed up. The holder is 11 inches in length, and the holder channel is fitted to contain a line of six, eight, or twelve such holders, according to the number of separate bands of heckling stocks in the machine. The head or holder channel has a falling and rising motion, by which it first presents the ends and gradually more and more of the length of the fibre to the heckle teeth, and, after dipping down the full length of the fibre exposed, it slowly rises and lifts the flax clear of the heckle stocks. By a reciprocal motion the whole of the holders are then moved forward one length; that at the last and finest set of stocks is thrown out, and place is made for filling in an additional holder at the beginning of the series. Thus with a six tool heckle, or set of stocks, each holder full of flax from beginning to end descends

FIG. 1. Section of Combe's Heckling Machine.

into and rise from the heckle teeth six times in travelling from end to end of the machine. The root ends being thus first heckled, the holders are shot back along an inclined plane, the iron plates clear the flax revers, and the top ends are then submitted to the heckling operation. The tow made in the heckling process is cleared from the heckle teeth, as they revolve, by doffers *l, l*, which in travelling upwards etc., by passing over special guide rollers *e, e*, projected out from the line of the heckle teeth. The doffers themselves are cleared by fixed combs *d, d*, and the tow falling down is collected in troughs *k, k* on each side of the machine. Tow, which is a much less valuable substance than dressed line, undergoes a somewhat different preparing process, and is used only for the lower numbers of yarn.

*Preparing.* The various operations in this stage have for their object the proper assortment of dressed line into qualities fit for spinning the different counts or sizes of yarn for which it may be suitable, and the drawing out of the fibres to a perfectly level and uniform continuous ribbon or sliver, containing throughout an equal quantity of fibre in any given length. From the heckling the now smooth, glossy, and clean stricks are taken to the sorting room, where they are a-sorted into different qualities by the "line sorter," who judges by both eye and touch the quality and capabilities of the fibre. So sorted, the material is passed to the spreading and drawing frames, a series or system of machines all similar in construction and effect. The essential features of the spreading frame are (1) the feeding cloth or creeping sheet, which delivers the flax to (2) a pair of "feed and jockey" rollers, which pass it on (3) to the gill frame or fallers. The gill frame con-

sists of a series of narrow heckle bars, with short closely studded teeth, which travel between the feed rollers and the drawing or "boss and pressing" rollers to be immediately attended to. They are, by an endless screw arrangement, carried forward at the rate at which the flax is delivered to them, and when they reach the end of their course they fall under, and by a similar screw arrangement are brought back to the starting point: and thus they form an endless moving level toothed platform for carrying away the flax from the feed rollers. The drawing rollers grip the fibre as it leaves the gill, and, as they revolve much more rapidly than the feeding rollers, the fibre is drawn out through the gill teeth say to twenty or thirty times the length it had on the feeding board, and is consequently reduced to a sliver or loose ribbon of correspondingly greater tenacity. The sliver from the drawing frame is delivered into a tin can which holds 1000 yards, and the machine automatically rings a bell when that length is delivered. From the spreading frame the cans of sliver pass to the drawing frames, where from four to twelve slivers combined are passed through feed rollers over gills, and drawn out by drawing rollers to the thickness of one. A third and fourth similar doubling and drawing may be embraced in a preparing system, so that the number of doublings the flax undergoes, before it arrives at the roving frame, may amount to from one thousand to one hundred thousand, according to the quality of yarn in progress. Thus, for example, the doublings on one preparing system may be  $6 \times 12 \times 12 \times 8 = 82,944$ . The slivers delivered by the last drawing frame taken to the roving frame, where they are singly passed through feed rollers and over gills, and, after drafting to sufficient tenacity, slightly twisted by flyers and wound on bobbins, in which condition the material—termed "rove" or "rovings"—is ready for the spinning frame.

The operation from the spreading frame to the roving frame is essentially one of doubling and drawing, and is consolidated with wool. A very important operation is the spreading of the flax, which is done in two principal ways, called respectively dry spinning and wet spinning, the first being used for the lower counts and the second for the higher counts manufactured. The spinning frame does not differ in principle from the throstle spinning machine used in the cotton manufacture. (Cotton, vol. vi p. 195) The bobbins of flax rove are arranged in rows on each side of the frame (the spinning frames being all double) on pins in an inclined plane A (fig. 2). The rove passes downwards through an eyelet or guide l to a pair of nipping rollers p, p, between which and the final drawing rollers c, c, placed in the case of dry spinning from 18 to 22 inches lower down, the fibre receives its final draft while passing over and under cylinders d and guide-plate g, and attains that degree of tenacity which the finished yarn must possess. From the last rollers the now attenuated material, passing to the flyer f, receives the degree of twist which compacts the fibres into the round hard cord which constitutes spun yarn; and from the flyers it is wound on the slowly rotating spool e within the flyer arms, centred on the spindle S. In wet spinning the general sequence of operations is the

same, but the rove, as unwound from its bobbin, first passes through a trough of water heated to about 120° Fahr.; and, moreover, the interval between the two pairs of rollers in which the drawing out of the rove is accomplished is very much shorter. The influence of the hot water on the flax fibre appears to be that it softens the gummy principle which binds the separate cells together, and thereby allows the elementary cells to a certain extent to be drawn out without breaking the continuity of the fibre; and further it makes a finer, smoother, and more uniform strand than can be obtained by y spinning. The extent to which the original strik of flax as laid on the feeding roller for (say) the production of a 50 lea yarn is, by doublings and drawings, extended, when it reaches the spinning spindle, may be stated thus:—35 times on spreading frame, 15 times on first drawing frame, 15 times on second drawing frame, 14 times on third drawing frame, 15 times on roving frame, and 10 times on spinning frame, in a 16,537,500 times its original length, with

FIG. 2.—Section of Dry Spinning Frame.

$8 \times 12 \times 16 = 1536$  doublings on the three drawing frames. That is to say, 1 yard of heckled line fed into the spreading frame is spread out, mixed with other fibres, to a length of about 9400 miles of yarn. In the case of fine yarns, by the additional doublings given, the doublings and elongations are very much greater.

The next operation is reeling from the bobbins into hanks. By Act of Parliament, throughout the United Kingdom the standard measure of flax yarn is the "lea," called also in Scotland the "cut" of 300 yards. The flax is wound or reeled on a reel having a circumference of 90 inches (2½ yards) making "a thread," and one hundred and twenty such threads form a lea. The grist or quality of all fine yarns is estimated by the number of leas in a pound; thus "50 lea" indicates that there are 50 leas or cuts of 300 yards each in a pound of the yarn so denominated. With the heavier yarns in Scotland the quality is indicated by their weight per "spindle" of 48 cuts or leas; thus "3 lb tow yarn" is such as weighs 3 lb per spindle, equivalent to "16 lea."

The hanks of yarn from wet spinning are either dried in a loft with artificial heat, or, in rural localities, exposed over ropes in the open air. When dry they are twisted back and forward to take the wry feeling out of the yarn, and made up in bundles for the market as "grey yarn." English and Irish spinners make up their yarns into "bundles" of 20 hanks, each hank containing 10 leas; Scotch manufacturers, on the other hand, adhere to the spindle containing 4 hanks of 12 cuts or leas.

Commercial qualities of yarn range from about 6 lb tow yarn (8 lea) up to 160 lea line yarn. Very much finer yarn up even to 400 lea may be spun from the system of machines found in many

factories; but these higher counts are only used for fine thread for sewing and for the making of lace. The highest counts of cut line flax are spun in Irish factories for the manufacture of fine cambrics and lawns which are characteristic features of the Ulster trade. Exceedingly high counts have sometimes been spun by hand, and for the preparation of the finest lace threads it is said the Belgian hand spinners must work in damp cellars, where the spinner is guided by the sense of touch alone, the filament being too fine to be seen by the eye. Such lace yarn is said to have been sold for as much as £240 per lb. In the Great Exhibition of 1851 yarn of 760 lea, equal to about 130 miles per lb, was shown which had been spun by an Irish woman eighty-four years of age. In the same exhibition there was shown by a Cambrai manufacturing firm hand-spun yarn equal to 1200 warp and 1600 weft or to more than 208 and 278 miles per lb respectively.

A large proportion of the linen yarn of commerce undergoes a more or less thorough bleaching before it is handed over to the weaver. Linen yarns in the green condition contain such a large proportion of gummy and resinous matter, removable by bleaching, that cloths which might present a firm close texture in their natural unbleached state would become thin and impoverished in a perfectly bleached condition. Manufacturers allow about 20 per cent. of loss in weight of yarn in bleaching from the green to the fully bleached stage; and the intermediate stages of "creamed," "half-creamed," "milled," and "improved," all indicating a certain degree of bleaching, have corresponding degrees of loss in weight. The differences in colour resulting from different degrees of bleaching are taken advantage of for producing patterns in certain classes of linen fabrics.

Linen thread is prepared from the various counts of fine bleached line yarn by winding the hanks on large spools, and twisting the various strands, two, three, four, or six cord as the case may be, on a doubling spindle similar in principle to the yarn spinning frame, excepting, of course, the drawing rollers. A large trade in linen thread has been created by its use in the machine manufacture of boots and shoes, saddlery, and other leather goods, and in heavy sewing-machine work generally. The thread industry is largely developed at Lisburn near Belfast, at Johnstone near Glasgow, and at Paterson, New Jersey, United States. Fine cords, net twine, and ropes are also twisted from flax.

**Weaving.**—The application of the power-loom to the weaving of linen was hindered by many obstacles which were not met with in dealing with the weaving of cotton and woollen fabrics. The principal difficulty arose through the hardness and inelasticity of the linen wefts, owing to which the yarn frequently broke under the sharp sudden jerk with which the picker throws the shuttle in power-loom weaving. The difficulties in the way of power-loom linen weaving, combined with the obstinate competition of distressed hand-loom weavers, delayed the introduction of factory weaving of linen fabrics for many years after the system was fully applied to other textiles. Competition with the hand-loom against the power-loom is conceivable, although it is absolutely impossible for the work of the spinning wheel to stand against the rivalry of drawing, roving, and spinning frames. To the present day, in Ireland especially, a great deal of fine weaving is done by hand-loom; and the persons who first applied machinery to the weaving of linen damasks in Scotland are yet (1882) alive. Power was applied on a small scale to the weaving of canvas in London about 1812; in 1821 power-looms were started for weaving linen at Kirkecaldy, Scotland; and in 1821 Maberly & Co. of Aberdeen had two hundred power-looms erected for linen manufacture. The power-loom has been in uninterrupted use in the Broadford factory, Aberdeen, which then belonged to Maberly & Co., down to the present day, and to that firm may be awarded the credit of being the effective introducers of power-loom weaving in the linen trade.

The various operations connected with linen weaving, such as winding, warping, dressing, beaming, and drawing-in, do not differ in essential features from the like processes in the case of cotton weaving, &c., neither is there any significant modification in the looms employed. Dressing is a matter of importance in the preparation of linen warps for beaming. It consists in treating the spread yarn with flour paste, applied to it by cylinders, the lowermost of which revolves in a trough of paste. The paste is equalized on the yarn by brushes, and dried by passing the web over steam heated cans before it is finally wound on the beam for weaving. See WEAVING.

For the bleaching and calendering of such linen fabrics as undergo these processes see BLEACHING vol. iii. p. 821; CALENDER, vol. iv. p. 682.

Linen fabrics are numerous in variety and widely different in their qualities, appearance, and application, ranging from heavy sailcloth and rough sack to the most delicate cambrics and lawns. The heavier materials include as a principal item sailcloth, with canvas, tarpaulin, oil-cloth, and carpeting. The principal seat of the manufacture of the cambric, Dundee, Arbroath, and Perth. The medium weight linen, which is used for a great variety of purposes, such as tent-making, travelling, cover, outer garments, for men, linings, upholstry, &c., includes duck, buckram, crash, tick, doilies, muslin, boy-shirting, and low brown linen. Plain bleached linens form the chief demand, and include principally the material for shirts and collars, and for bed sheet. Under the head of twilled linens are included shillings, diapers, and dimity for men's clothing; and drapery for table linen, of which two kinds are of fine quality—sageen for bed and work, and double or high-shate duck, the pattern being formed by the inter-section of warp and weft various intervals of five and eight strands of yarn respectively. The fine linens are cambrics, lawns, and handkerchiefs; and betty, printed and creased linens may be assigned to a special though not important class. New materials, fancy, and temporary fancies are frequently attracted to linen fabrics; but in the above list are only included such articles as occupy a standing position in the markets. Being ready way it may be said regarding the British industry that the heavy linen trade centres in Dundee; medium goods are made in a few linen manufacturing districts; duck and shillings produced in Dundee and Perth, and the fine lawn manufactures have their seat in Belfast and the north of Ireland. Goods of the same kind are made in Scotland and England.

Linen fabrics have several advantages over cotton, resulting principally from the microscopic structure and length of the flax fibre. The cloth is much smoother and more lustrous than cotton cloth, and presenting close "wavy" surface, does not soil so readily, nor absorb and retain moisture so freely as the more spongy cotton; and it is stronger, cooler, cleaner, and holds fast a natural gloss, fast colouring and finishing. Bleached linen, starched and pressed, has a that unequalled purity, gloss, and smoothness which make it stand the natural rival for shirt-fronts, collars, and wristbands, and the guaranteed heavy yet smooth cloth of the thread it may be spun into fits it for the most delicate work to which it is devoted. Flax is a heavier material than cotton, but would for weight it is much stronger, single yarn having proportionate strength in the ratio of 3 to 1·83, doubled yarn 3 to 2·26, and cloth 3 to 2·13. Of course cotton, on the other hand, has many advantages peculiar to its own.

**Trade and Commerce.**—The application of machine power to the manufacture of linen manufactures has greatly improved the position and developed the resources of the industry, so that linen now occupies a well-defined and important position among the principal textiles. Had it not been for the sudden and unprecedented growth of the jute trade, no doubt the coarser and heavier branches of the trade would have attained much greater dimensions; and the development of the jute industry of Scotland fully accounts for the comparatively indolent condition of the Scottish linen trade.

The following table indicates the extent of the linen industries in the United Kingdom at the various dates specified.

	1856	1861	1871	1880
Number of factories . . .	41	29	50	—
"    spindles . . .	288,000	1,217,000	1,771,000	1,700,000
"    power-looms . . .	8,684	14,792	35,541	41,000
Horse-power . . .	11,984	31,727	52,001	—
Weft . . .	3,935	1,754	—	—
Persons employed—				
Ireland . . .	28,753	33,225	30,000	—
Scotland . . .	31,722	33,589	40,000	—
England . . .	19,787	20,405	19,000	—
Total . . .	80,262	87,229	109,000	—

It is only in Ireland that the linen industries during the above period have exhibited a healthy expansion. To that country alone the following figures apply:—

	1856.	1861.	1870.	1880.
Number of factories .....	113	217	312	...
"    spindles.....	568,000 (1859)	593,000	867,000 (1871)	911,000
"    power-looms .....	3,633	4,933	14,509	21,153

The number of flax spindles and power-looms in the European factories in 1881 is given in the *Annual Report of the Irish Flax Supply Association* as follows:—

	Spindles.	Power- Looms...		Spindles.	Power- Looms
Ireland .....	879,875	21,177	Russia .....	160,000	...
Scotland .....	263,264	16,756	Italy .....	...	...
England .....	190,808	4,081	Switzerland .....	9,000	...
France .....	170,000	22,000	Holland .....	7,700	1,200
Austria-Hungary .....	80,440	500	Sweden .....	3,810	98
Germany .....	318,667	8,000	Spain .....	...	1,000
Belgium .....	295,110	4,755			

In all these returns no account is taken of the hand-looms in use, although in most of the Continental districts hand-loom weaving is more common than weaving by power.

The amount and declared value of the exports of linens, linen yarn, &c., from the United Kingdom at intervals extending over fifty years is thus stated from official sources:—

Year.	Linen Manufactures.		Linen &c.		Yarns.	
	Yards.	Value in £	Value in £	lb	Value in £	
1831	63,284,892	2,400,017	91,631	...	...	...
1841	90,321,761	3,194,827	111,261	17,333,575	822,866	...
1851	129,109,753	3,822,915	284,461	...	...	...
1861	116,122,109	3,571,131	269,774	27,981,012	1,522,216	...
1871	220,467,476	6,911,223	702,703	36,235,635	2,218,129	...
1881	173,853,300	5,163,669	680,260	18,283,500	1,067,172	...

The principal consumers of British linen manufactures are indicated in the following table, showing the exports for the year 1881:—

Country.	Piece Goods.		Yarns.	
	Yds	Value in £	lb	Value
United States .....	82,030,900	2,114,910	...	...
Spanish West Indies .....	11,028,500	147,664	...	...
Australia .....	13,526,200	401,917	...	...
Germany .....	1,980,500	209,223	2,476,500	209,165
British North America .....	281,000	175,757	...	...
France .....	318,000	173,924	1,527,200	182,164
Holland .....	298,800	11,241	2,438,100	102,564
Belgium .....	...	...	1,629,500	12,619
Spain and Cuba .....	...	...	...	...
Other countries .....	759,000	1,989,477	3,661,600	177,618
Total .....	915,500	4,836,582	18,283,500	1,067,172
To which add:—

		5,337,101		

LING (*Molva vulgaris*), a fish of the cod-fish family (*Gadidae*), readily recognized by its long body, two dorsal fins (of which the anterior is much shorter than the posterior), single long anal fin, separate caudal fin, a barbel on the chin, and large teeth in the lower jaw and on the palate. Its usual length is from 3 to 4 feet, but larger individuals of 5 or 6 feet in length, and some seventy pounds in weight, have been taken. The ling is found in the North Atlantic, from Spitzbergen and Iceland southwards to the coast of Portugal. Its proper home is the German Ocean: especially on the coasts of Norway, Denmark, Great Britain, and Ireland it occurs in great abundance, generally at some distance from the land, in depths varying between 50 and 100 fathoms. During the winter months it approaches the shores, when great numbers are caught by means of long lines. On the American side of the ocean it is less common, although generally distributed along the south coast of Greenland, and on the banks of Newfoundland. This fish is one of

the most valuable species of the cod-fish family; a certain number are consumed fresh, but by far the greater portion are prepared for exportation to various countries on the Continent (Germany, Spain, Italy). They are either salted and sold as "salt-fish," or split from head to tail and dried, forming, with similarly prepared cod and coal-fish, the article of which during Lent immense quantities are consumed in Germany and elsewhere under the name of "stock-fish." Also the oil is frequently extracted from the liver and used by the poorer classes of the coast population for the lamp or as medicine.

LING. See HEATH.  
LINGARD, JOHN (1771-1851), the Roman Catholic historian of England, was born of humble parentage at Winchester on February 5, 1771. His intellectual abilities began to manifest themselves at a very early age, and in 1782 he was sent to the English college at Douay, where he continued until shortly after the declaration of war by England (1793). For some time after his return to England he lived as tutor in the family of Lord Stourton, but in October 1794 he settled along with seven other former members of the old Douay college at Crook Hall near Durham, where on the completion of his theological course he became vice-president of the reorganized seminary. In 1795 he was ordained priest, and soon afterwards undertook the charge of the chairs of natural and moral philosophy. In 1808 he accompanied the community of Crook Hall to the new and more commodious buildings at Ushaw, Durham, but in 1811, after declining the presidency of the college at Maynooth, he withdrew to the secluded mission at Hornby in Lancashire, where for the rest of his life he found the leisure which his literary pursuits demanded. In 1817 he visited Rome, where he made some researches in the Vatican Library, and also negotiated some business connected with the English college. In 1821 Pope Pius VII. created him doctor of divinity and of canon and civil law; and in 1825 Leo XII. is said to have made him cardinal *in petto*. He died at Hornby on July 17, 1851.

Lingard was the author of a considerable number of occasional and ephemeral writings of an avowedly controversial character. He also wrote *The Antiquities of the Anglo-Saxon Church* (1806), of which a third and greatly enlarged addition appeared in 1845 under the title *The History and Antiquities of the Anglo-Saxon Church; containing an account of its origin, government, doctrines, worship, revenues, and ecclesiastical and monastic institutions*; but the work with which his name is chiefly associated is *A History of England, from the first invasion by the Romans to the commencement of the reign of William III.*, which appeared originally in 8 vols. at intervals between 1819 and 1830. Three successive subsequent editions had the benefit of extensive revision by the author; a fifth edition in 10 vols. 8vo appeared in 1819, and a sixth, with life of the author by Tierney, prefixed to vol. x., in 1854-55. Soon after its appearance it was translated into French, German, and Italian. It is a work of ability and research; and, though Cardinal Wiseman certainly claimed too much for its author when he called him "the only important historian of our country," yet the candid and dispassionate student will always find it profitable to learn from the pages of Lingard the aspects which the events of English history presented to the mind of an able and intense Roman Catholic in the earlier decades of the 19th century.

LINKÖPING, a city of Sweden, the see of a bishop, and the chief town of the province of East Gothland, is situated in a fertile plain 21 miles by rail south-west of Stockholm, and communicates with Lake Roxen ( $\frac{1}{2}$  mile to the north) and the Gata and Kilda canals by means of the now navigable Stångå. Most of the houses are of wood. The cathedral (1150-1499), a Romanesque building with a Gothic choir, is, next to the cathedral of Upsala, the largest church in Sweden, and, since the cathedral of Trondhjem has lost so many of its treasures, presents the richest variety of objects of interest to the student of mediæval art in the country. In the church of St Lawrence, also called the Church of the Estates, are some paintings

by Hörberg, the Swedish peasant artist. Other buildings of note are the massive old episcopal palace (1470–1500), afterwards a royal palace, and the old gymnasium founded by Gustavus Adolphus in 1627, which contains a valuable library (30,000 volumes) of old books and manuscripts, formerly kept in the cathedral. The population, 3285 in 1810, was 8706 in 1878.

Linköping early became a place of mark, and was already a bishop's see in 1082. It was at a council held in the town in 1153 that the payment of Peter's pence was agreed to at the instigation of Nicholas Breakspere, afterwards Adrian IV. The coronation of Birger Jarlsson Waldemar took place in the cathedral in 1251; and in the reign of Gustavus V. several important diets were held in the town. A large portion of it was burned down in 1700.

**LINLITHGOW**, or **WEST LOTHIAN**, a county of Scotland, stretching for 17 miles along the south coast of the Firth of Forth, and bounded E. and S.E. by Edinburghshire or Midlothian, S.W. by Lanarkshire, and W. by Stirlingshire. It lies between 55° 49' and 56° 1' N. lat., and 3° 18' and 3° 51' W. long. According to the ordnance survey the area is 127 square miles, or 81,114 acres, a considerable increase on previous estimates. The longest straight line that can be drawn within the county is one of about 22 miles from north-east to south-west, but the average length does not exceed 16 miles, and the average breadth is about 7. To the east and west the boundaries are in the main natural, following in the one case the Almond and the Breich Water (except in the neighbourhood of Mid Calder, where Edinburgh encroaches on Linlithgow), and in the other the Avon and Drumtassie Burn. To the south they are more conventional, the line of the watershed between the Clyde and the Forth being disregarded, and a good deal assigned to Lanarkshire which physically belongs to the Lothians. The whole county lies in the basin of the Forth, and there is a general slope upwards from the shore of the firth to the hilly district in the south-west. The surface is diversified by hill and dale, and, with the exception of the upland moors on the borders of Lanarkshire, there is no extensive tract of level ground. A kind of irregular valley stretches across the county from east to west, affording the most convenient route for road, canal, and railway. Between this valley and the firth runs a line of crags and hills often beginning to rise immediately behind the shore; the more prominent are Dalmeny, Dundas, the Binns, and Glowerowrem or Bonnytownhill, the last a rounded eminence 559 feet above the sea, crowned by a conspicuous monument to General A. Hope, who fell in the Indian mutiny of 1858. To the south of the valley the ground rises pretty rapidly towards the west, more gradually towards the east. Between Bathgate and Linlithgow a general height is obtained of from 600 to 700 feet,—the principal eminences being Knock (1017 feet), Cairnpaple or Cairnnaple (upwards of 1000), the Torphichen Hills, Bowden (749), and Cockleroy (942). Farther east come the Riccarton Hills; and the range may be said to terminate with Binny Craig, a striking crag-and-tail similar to those of Stirling and Edinburgh. To the south-east stands the isolated Dechmont Law (686 feet).

There is no stream of any considerable size belonging exclusively to the county. The Almond rises in Lanarkshire, enters Linlithgowshire near Falkemmet, receives the White Burn and the Black Burn, and joining the Breich Water (also from Lanarkshire) passes Livingston, Mid Calder (Midlothian), and Kirkliston, and reaches the firth across the Drum Sands at Cramond. The Avon, which is already nearly as large as it ever becomes, when it reaches the borders of the county below Muiravonside, passes Linlithgow bridge and Kinneil, and falls into the firth some distance below Inveravon. With the exception of

Lochcot, the only lake in the county is Linlithgow Loch, a sheet of water covering 102 acres to the north of the town, well-known as a meeting place for curling and skating clubs. The eastern end is not more than 10 feet deep, but in the western portion there is one place about 50 feet deep. Eels are still caught in great numbers; and the perch and the worthless roach, locally called the braise, are abundant. See **LAKE**, p. 220.

"The eastern portion of the county," says Mr H. M. Cadell, "consists of Lower Carboniferous Sandstones, thin estuarine limestones, and shales. The Carboniferous Limestone series, to which the strata in the western portion belong, is separated from the underlying Calciferous Sandstone series by the Carboniferous or Mountain Limestone, which dips westward and is well exposed along the outcrop in the disused lime-quarries of Hillhouse, Silvermine, and Bathgate. The overlying rocks consist of sandstones, shales, and coal-seams, which are worked at Bathgate and Bo'ness, above which come the three upper marine bands named respectively the Index, the Calmy or Janet Peat, and the Castleary or Levensat Limestone, the last of which is taken as the top of the Carboniferous Limestone series and the base of the Millstone Grit. The strata containing most of the workable coals at Bo'ness have a thickness of about 150 fathoms, measuring from the Index Limestone to the lowest seam. The extensive sheets of contemporaneous volcanic rocks (basalts, dolerites, and tuffs) form a remarkable feature in the geology of the county. The high ground between Linlithgow and Bathgate is formed of an almost uninterrupted pile of these rocks about 2000 feet in thickness. They thin out towards the north and south, and on the shore of the firth they occur regularly interbedded with the seams of the Bo'ness coal-field, which are usually in no degree injured by their presence. The tuffs or ash beds are well seen at Preston Burn, Carriden House, and St Magdalen's near Linlithgow, while Binns Hill near Blackness is the remnant of an old volcano of Lower Carboniferous age. Trap dykes rise through the strata and run in an east and west direction, one of which can be traced for 4 miles between Parkly Craigs and the Avon." A few mineral springs, sulphurous and chalybeate, are known to exist in the county, but none of them are now of medical repute. In 1875 a salt spring was discovered in the volcanic rocks to the west of the town of Linlithgow, boring having been prosecuted to the depth of 151 feet in search of drinking water. (See *Proc. Roy. Soc. Edin.*, 1875.) Coal-mining has been prosecuted in the county probably from the time of the Romans; and the earliest document extant in regard to coal-pits in Scotland is a charter granted about the end of the 12th century to William Oldbridge of Carriden. In 1871 it was estimated by the Government commissioners that the Linlithgow coal-fields still contained 127,621,800 tons of coal accessible at depths not exceeding 1000 feet. About 1110 miners were employed in the twenty coal-mines in 1881, and the output for the year was 501,338 tons. At the same date there were six iron mines in operation, with 926 miners and an output of 180,191 tons. The Kinneil Company, which is the largest in this department, employs about 700 persons. Fire-clay is worked in connexion with the coal; at Kinneil 60,000 bricks can be turned out per week. Since their value was made apparent by Mr Young about 1850, the shales have been the object of an extensive industry at Broxburn, Uphall, Dalmeny, and Hopetoun. The six mines in 1881 employed 691 miners, and the output was 353,826 tons. Limestone, freestone, and whinstone are all quarried within the county, and the Binny freestone has been used for the Royal Institution, the National Gallery, and many of the principal buildings of both Edinburgh and Glasgow. As a manufacturing district Linlithgow does not stand high,—the chief estab-

ishments, apart from those mentioned in connexion with the town, being grist-mills, distilleries, chemical works, glass works, spade and shovel works, and a pottery.

The climate of the county hardly differs from that of the western portion of Midlothian. The annual rainfall, however, is somewhat greater, and is a fifth more than that of East Lothian: for the twenty-one years ending 1880 the mean at Linlithgow was 31·76 inches, while at East Linton (east of Haddington) it was 26·52.<sup>1</sup>

Linlithgow is classed as a mixed agricultural and pastoral county; the agricultural element, however, preponderates largely, though the area of permanent pasture has been increasing. It is calculated that of the total area of 81,111 acres about 20,000 acres consist of the best sorts of clay (carse, &c.), 22,700 of clay on a cold bottom, 9500 of loam, as much of light gravel and sand, 14,000 of moorland and high rocky ground, and 1500 of peat. Only a very small part of the arable land remains unreclaimed; the parish of Livingston, which in the beginning of last century was nearly covered with heath and juniper, is now all under rotation. Bathgate and Torphichen contain patches of peat moss and swamp. In Carriden and Dalmeny, and generally along the coast, the soil is light and early, though in some parts it varies so often that no single term is applicable to any considerable area. According to the agricultural returns for 1881, the corn crops occupied 17,317 acres, green crops 7264, clover and grass under rotation 12,980, permanent pasture (exclusive of heath or mountain land) 21,289. Oats are the most important of the cereals, 10,318 acres; and barley comes next with 1874 acres, an increase on the 3787 acres of 1856. Wheat has been steadily losing ground; while 1856 showed 4613 acres, 1881 gives only 1450. Beans, which used to occupy about 1000 acres, are now reduced to 655. An increasing area is devoted to shaver and grass for hay; but on the other hand the turnip area has been considerably reduced—5142 acres in 1856, 3861 in 1881. The extent of land under potatoes has slightly increased, 3052 acres for 1881, 2455 being the average for 1860-75. Cattle-breeding is not much attended to, but a considerable number of animals are bought and fattened, and dairy farming is largely presented, the fresh butter and churn milk being sent mainly to Edinburgh, but also to Newcastle, &c. Very little cheese is made. As a sheep-farming county Linlithgow stands very low—the returns giving 17,605 head in 1881, 23,070 in 1866. But few horses are bred, and the number of those in the county has remained wonderfully small for the last fifteen years. Pigs have grown greatly fewer—3163 in 1866, and only 1442 in 1881.

The average extent of the farms is 108 acres, rather less than in Midlothian, of the total 542 more than 200 do not exceed 50 acres, and only 25 rise above 300. Very little of the land is rented at more than £3 per acre; an average of £2 to £2·10s. for the best districts, of 30s. to 35s. for medium soils, and 15s. to 25s. for the worst land, will not be wide of the mark. The leases of the arable lands are almost all for 19 years, and the pasture lands are usually let accordingly by public auction, though in some instances they are taken for a period of three or five years.<sup>2</sup>

Though it is only in the neighbourhood of the principal mansions that large stretches of wood exist, the county as a tree-growing district rises considerably above the average for Scotland, the woodland in the county returning 145,429 acres in 1881, or one-sixteenth of the whole of Linlithgow (about one-twentieth). The finest woods are those of Hopetoun, where the larch avenues are especially noteworthy. Next come Kinnell, and Dalmeny. Much of the old timber has been recently cut down, but replanting has been vigorously prosecuted.

The valuation of the county in 1641 was £75,027 Scots, or about £252 sterling. In 1806 the total was £61,518 sterling, and in 1811, £88,745. Exclusive of railways, the valuation was £183,198 in 1876-77, and £216,911 in 1881-82. In the beginning of the century the county was practically in the hands of a few noblemen and forty landowners (Trotter). According to the Government return for 1872-73, the total number of owners was 1535, of which 257 possessed upwards of 1 acre. The proprietors holding 1000 acres or above 2000 acres were as follows:—Earl of Hopetoun, 11,759 acres; Earl of Rosebery, 5680; Sir William Balcanquhall of Balcanquhall, 4320; Duke of Hamilton's Trustees, 3694; Lord Cardross, 2955; William Cowan of Linburn, 2231; Robert H. J. Stewart of Clackmannan, 2036; Dundas's Trustee, 2032.

Hopetoun House, the seat of the Earl of Hopetoun, and the grandest mansion in the county, occupies a fine position between Queensferry and Blackness. Begun about 1696 by Sir William Bruce of Kintore, and completed long afterwards by Mr Adam, it partially occupies the site of the old castle of Abercorn, which

was taken from the Douglas family by James II. in 1455. Dalmeny Park (earl of Rosebery) lies about 1½ mile west of Cramond; the neighbouring ruins of Barnbougle Castle, an ancient seat of the Mowbrays, have been incorporated with a modern building. Almondell House (earl of Buchan) is situated on the Almond, not far from Mid Calder. Kinnell, a now deserted residence of the dukes of Hamilton, associated with memories of Colonel Lilburn and Dugald Stewart, is a short distance to the south-west of Bo'ness. On a trap rock jutting out into the firth stands Blackness Castle, now used as a powder magazine, but once one of the "keys of the kingdom," with a busy little port under its protection. Niddry Castle (often called West or Seton Niddry), one of the resting places of Queen Mary, is now a mere ruin. Newliston (now owned by T. A. Hog) was for many years the residence of Lord Stair, who first introduced the field cultivation of cabbage, and is said to have laid out the woods according to the plan of the battle of Dettingen. Dundas Castle was the original seat of the Dundas family. Pardovan recalls the memory of Walter Stewart, author of the *Collocations concerning the Worship, &c., of the Church of Scotland*, and Philipstown that of John Dundas, another Scottish ecclesiastical lawyer. Kinnell was the birthplace and family mansion of Patrick Hamilton.

There are two royal burghs in the county: Linlithgow and Queensferry, and, besides, the towns Bathgate, Borrowstounness or Bo'ness, Armadale, a number of thriving villages.

The Union Canal connecting the Forth and Clyde Canal with Edinburgh passes along the central valley, and crosses the Almond and Avon by bridges designed by Thomas Telford. The North British Railway has two lines between Edinburgh and Glasgow, which pass through the county *via* Linlithgow and Bathgate respectively. Queensferry and Bo'ness are both connected with the system by branch-lines, and Bathgate is a junction of some importance.

The population of West Lothian has increased from 17,844 in 1801 to 43,198 (22,436 males and 20,762 females) in 1881. The greatest increase (8601) took place in the decennial period 1851-1861, the last (606) in 1811-21. The females were in excess of the males in every census down to 1841; since then the preponderance has been on the other side. The total population was 23,291 in 1831, 26,872 in 1841, 30,041 in 1851, 38,645 in 1861, and 40,905 in 1871.

Traces of the prehistoric occupation of the county are fairly numerous. On Bowden Hill is an earthwork connected by Mr Glennie and others with the Arthurian contest. On Cairnpaple may be seen a circular building of unknown but early origin, and at Kippis is a cromlech once surrounded by circles of stones. Stone cists have been discovered at Carlwrie, Dalmeny, Newliston, &c. Near Inveravon is a vast accumulation of shells considered by several geologists to be a natural bed, but claimed by antiquaries as an artificial mound, either a kitchen midden or a heap for the manufacture of lime (see David Grieve, *Proc. Sc. Soc. of Ant.*, 1870-71). The Wall of Antoninus lies for a considerable distance within the county, and is believed to give origin to the names Carriden and Wulton (see an account of a detailed exploration of the wall in *Bulldoz*, 1877, pp. 1023-25). A fine Roman tablet was discovered at Bridgeness in 1868 (*Proc. Sc. Soc. of Ant.*, vol. viii.). Roman camps can be distinguished in several places.

At Torphichen are the remains of a preceptory of the Knights of John of Jerusalem, partly used as a parish church. The churches of Dalmeny, Abercorn, Kirkliston, Uphall, and South Queensferry are of early origin,—Romanesque and Norman Gothic.

LINLITHGOW, the county town of the above county, and a royal and parliamentary burgh, situated in the central valley, 18 miles by rail from Edinburgh, consists almost exclusively of a single street running east and west along both sides of the highway; gardens behind the houses stretch down to the lake or climb the lower slopes of the rising grounds, on which a considerable number of suburban residences have been erected. In the early part of the century the general aspect of the street was antique and picturesque, but the greater proportion of the frontage has been rebuilt or modernized. Apart from the palace and the contiguous church of St Michael, the only edifices of any note are an ancient towerlike building near the railway station, which tradition regards as a mansion of the Knights Templars, the town-house (1688), and the county courts (1865). "Linlithgow for wells" is a proverbial expression; and the cross well in the public

<sup>1</sup> For further notice of rainfall, &c., see Trotter's *Agriculture of West Lothian*.

<sup>2</sup> Thomas Farrall, in *Trans. of Highland and Agric. Soc. of Scotland*, 1877.

<sup>3</sup> See *Abstract of the Charters . . . in the Charters of Torphichen* (ed. 1830).

square in front of the town-house is a striking piece of grotesque carved work in stone, originally erected, it is believed, in the reign of James V., but rebuilt in 1807. The burgh school goes back to the pre-Reformation times. Shoemaking and tanning are the leading industries; but a large distillery and (in the neighbourhood) two paper mills, glue works, and a soap-factory add considerably to the business of the place. Linen bleaching is altogether a thing of the past. A grain market is held every Friday. The riding of the marches of the burgh is still performed annually by the magistrates and trades. The population of the burgh was 2282 in 1792-93, 3843 in 1861, 3690 in 1871, and 3913 in 1881.

Lindlithgow Palace is by general consent the finest ruin of its kind in Scotland. Heavy but effective, the sombre walls rise above the green knolls of the promontory which divides the lake into two nearly equal portions. In plan it is almost square (168 by 171 feet), enclosing a court (91 by 88 feet), in the centre of which stands the ruined fountain used as a model for that erected in front of Holyrood Palace. At each corner there is a tower with an internal spiral staircase,—that of the north-west angle being crowned by a little octagonal turret known as “Queen Margaret’s Bower,” from the tradition that it was there that the consort of James IV. sat and watched for his return from Flodden. The oldest portion of the building is probably the west side, whose massive masonry, hardly broken by a single window, is supposed to date in part from the time of James III.; but the larger part of the south and east sides belong to James V., about 1535; and the north side was rebuilt in 1619-20. Of James V.’s portion, which is architecturally the richest, the main apartments are the Lyon chamber or parliament hall, and the chapel royal. The grand entrance approached by a drawbridge, was on the east side; above the gateway are still some weather-worn remains of rich allegorical designs, once resplendent with colour. A few yards to the south of the palace is the church of St Michael, a Gothic (Scottish decorated) building (180 feet long internally excluding the apse and the steeple, by 62 in breadth excluding the transepts) probably founded in 1242, but mainly built in the 15th century. The central west front steeple was till 1821 topped by a crown like that of St Giles, Edinburgh.<sup>1</sup>

Lindlithgow (wrongly identified with a Roman Lindum) was a royal burgh with a royal castle and an endowed church as far back as the reign of David I. Edward I., who had encamped there the night before the battle of Falkirk (1298), wintered at Lindlithgow in 1301, and next year built “a pele castle mekill and strong,” which in 1313 was captured by the Scots through the assistance of William Bunnock or Buning and his famous hay-cart. Later in the century (1369) the customs of Lindlithgow yielded more than those of any other chief town except Edinburgh; and the burgh was taken along with Lannark to supply the place of Berwick and Roxburgh in the coat of the Four Burghs (1368). Robert II. granted it a charter of immunities, the oldest still preserved, in 1384. The palace becoming a favourite residence of the kings of Scotland, and often forming part of the marriage settlement of their consorts (Mary of Guelders, 1419; Margaret of Denmark, 1468; Margaret of England, 1503), is frequently mentioned in Scotch history. James V. was born within its walls in 1512, and his daughter Mary, December 7, 1542. In 1570 the Regent Murray was assassinated in the High Street by Hamilton of Bothwellhaugh. In 1600 the title earl of Lindlithgow was bestowed on Alexander, Lord Livingston, by James VI., who after his accession to the English throne retained an affection for the palace, and visited it again in 1617. The university of Edinburgh took refuge at Lindlithgow from the plague in 1615-16; and in the same year the national parliament, which had often sat in the palace, was held there for the last time. The public burning of the Covenant (1661), the passing of Prince Charles through the town in 1745, and the burning of the palace by Hawley’s dragoons in 1746 are the chief remaining facts in the local annals. Most of the privileges which Lindlithgow enjoyed have dropped away. The rise of Bo’ness gave the last blow to the prosperity of its port at Blackness; its burgh lands have all been sold; and, after gaining its case three times in the Court of Session, it was deprived (1859) by the House of Lords of any claim to levy bridge toll and custom from the Edinburgh and Glasgow Railway.

LINNÆUS (1707-1778). Carl von Linné, better known under his earlier name of Carolus Linnaeus, was born 13th May 1707 o.s., at Råshult, in the parish of Stenbrohult, in the province of Småland, Sweden.<sup>2</sup> His parents were Nils Linnaeus, the comminister, afterwards pastor, of the parish, and Christina, the daughter of Broderonius, the previous incumbent; Carl, the subject of our notice, being their eldest child. When only four years old he was much impressed with his father’s conversation with some of his people concerning the properties and names of certain of the local plants of economic value; from that time he constantly asked his father about the quality and nature of every plant he met with, often asking more than his father could answer; at other times, having forgotten the information previously given him, he was threatened with a refusal to answer his queries unless he promised to remember what he was told. To this early discipline Linnaeus afterwards ascribed his tenacious memory, which, added to his extreme sharpness of sight, laid the foundations of his eminence as a reforming naturalist.

His formal education began in 1714, when he was put under the private tuition of Telander, and three years later he entered the primary school at Wexiö. In 1719 he was committed to the care of Gabriel Hok, who afterwards married his pupil’s sister Anna Maria; this preceptor had greater skill as a teacher than his predecessors, and was less severe; still he was unable to overcome the distaste the youth had acquired for ordinary scholastic studies. During his last years at school Linnaeus took advantage of the greater liberty then allowed him to ramble in search of plants.

In 1721 he passed from the school to the gymnasium, carrying with him the same dislike for all those studies which were considered necessary for admission to holy orders, his father’s intention being to bring up his son in his own profession. Botany, a science at that time entirely neglected, almost wholly engrossed his attention; he formed a small library of the few Swedish writers who had treated of plants, which he was constantly poring over, although unable to comprehend all he found in their volumes.

In 1726 his father came to Wexiö, hoping to hear a good report of the two years’ study of his son; but, whilst there was no complaint as regards his moral deportment, his progress in the prescribed studies had been so unsatisfactory that his father was recommended to apprentice him to a taylor or shoemaker, in preference to giving him a learned education, for which he was evidently unfitted. The old clergyman, deeply grieved at this poor return for his struggles to keep his son at school during the previous twelve years, went to visit Dr Rothman, a medical practitioner and lecturer on physics in the town, to consult him regarding a bodily ailment from which he was suffering. In the course of conversation he mentioned his mortification at his son’s dulness, when Rothman expressed his confident belief that he could end the troubles of both father and son, and that Carl, though extremely backward in theological studies, would yet distinguish himself in medicine and natural history. Rothman further offered to board and lodge Carl during the twelvemonth more which must be passed in the gymnasium. A short time after this, Rothman gave his pupil a course of private instruction in physiology with great success, the young man acquitting himself excellently on examination. His tutor also gave

<sup>2</sup> The new style being then in process of gradual adoption in Sweden, the year 1704 was regarded as a common year in that country; consequently the true date of Linnaeus’s birth, according to our present reckoning, was 23d May 1707, the commonly received date—24th May, being an error due to supposing the calendar in Sweden and this land at that time to be identical.

him hints as to the proper manner of studying plants, and directed his attention to Tournefort's system of arrangement, which was founded on the differences in the flowers.

He proceeded to the university of Lund in 1727, bearing a dubious worded testimonium from Nils Krok, the rector of the gymnasium, to the effect that shrubs in a garden may disappoint the cares of the gardener, but if transplanted into different soil may prosper, therefore the bearer was sent to the university, where, perchance, he might find a more propitious climate. His former preceptor Håk kept back this doubtful recommendation, and presented Linnæus to the rector and dean as his own private pupil, thus procuring his matriculation.

Whilst studying here, Linnæus lodged at the house of Dr Kilian Stobæus, afterwards professor of medicine, and physician to the king, who possessed an excellent museum of minerals, shells, birds, and dried plants; the methods of preservation here adopted were as a revelation to the young student, and taught him how to prepare his own acquisitions. Stobæus suffered greatly from ill-health, he was also lame, and one-eyed; but he was an amiable and extremely able man, having a large practice among the wealthier classes in the province of Skåne. Linnæus was sometimes called upon to assist the physician by writing the prescriptions, but as he wrote a bad hand, he was frequently sent away again. In those days physicians wrote legibly.

A German student named Koulas also lodged with Stobæus, and amongst the indulgences he enjoyed was that of access to the library of his landlord; with his fellow-student Linnæus formed a close friendship, and in return for instruction in the physiology which Linnæus had learned of Dr Rothman, Koulas supplied him with volumes from the book-shelves of Stobæus, which were read by him stealthily at night. The mother of Stobæus, who was old and wakeful, noticed that there was constantly a light in Linnæus's room, and, being afraid of fire, desired her son to reprimand the young man for his carelessness. Two nights afterwards, Stobæus went into Linnæus's chamber at eleven o'clock, expecting to find him asleep, but was astonished to find him poring over books. He was forced to confess whence these were obtained, and was at once ordered to bed: but the next morning, being further questioned, he was granted full liberty to use the library, and perfect familiarity was accorded by the doctor, who, having no children, held out hopes of making the young student his heir.

Whilst botanizing in the spring of 1728, Linnæus was attacked by what he considered to be a venomous animal, afterwards named by him *Furia infernalis*, in allusion to the torment and danger he suffered from it; after his recovery, he passed the summer at his father's house in Småland. Here he again met Rothman, who strongly advised him to quit Lund and to go to Upsala, where he would find greater facilities for the prosecution of his medical studies, and possibly obtain some scholarship to eke out his scanty means. Linnæus adopted his patron's advice, and started for Upsala with a sum of £8 sterling, that being all he was to expect from his parents. At this seat of learning his slender funds were soon exhausted; being young and unknown, he found no means of earning money by lecturing or teaching; he became dependent on chance generosity for a meal, and had to repair his shoes with folded paper. He could no well return to Lund, for Stobæus had taken offence at his departing without consulting him; and, besides, the journey required money which he did not possess.

In the autumn of this year, 1729, Linnæus was engaged intently examining some plants growing in the academical garden, when a venerable clergyman asked him what he

was studying, whether he understood botany, whence it came, and how long he had been busied in the study. After being questioned at length, he was requested to follow his companion home; there he discovered him to be Dr Olaf Celsius, professor of theology, at that time working at his *Hierobotanicon*, which saw the light nearly twenty years later. When the professor saw Linnæus's collections he was still more impressed, and, finding him necessitous, he offered him board and lodging; he afterwards admitted him to close intimacy, and allowed him the free use of his rich library. The temporary adjunctus of the faculty of medicine being incompetent, Linnæus, by the recommendation of Celsius, was able to get some private pupils, and thereby to assume a more creditable appearance.

At this time there was only one medical student who distinguished himself by diligence in study, and that was Peter Arctedius, who afterwards styled himself Artedi. A close friendship sprang up between the two young men; they studied in concert, and vied with each other in their attainments, with perfect good temper, though of very diverse dispositions. Linnæus was sovereign in ornithology, entomology, and botany, Artedi reserving to himself the umbelliferous plants, fishes, and amphibia. A silence, almost total, prevailed in the university at this time on topics of natural history; during his whole curriculum Linnæus did not hear a single public lecture delivered on anatomy, botany, or chemistry.

During this period of intense receptivity, he came upon a critique which ultimately led to the establishment of his artificial system of plant classification. This was a review of Vaillant's *Sermo de Structura Florum*, Leyden, 1718,<sup>1</sup> a thin quarto in French and Latin; it set him upon examining the stamens and pistils of flowers, and, becoming convinced of the paramount importance of these organs, he formed the idea of basing a system of arrangement upon them. Another work by Wallin, *Γάμος φέρων, sive Nuptiæ Arborum Dissertatio*, Upsala, 1729, having fallen into his hands, he drew up a short treatise on the sexes of plants, and showed it to Dr Celsius, who put it into the hands of the younger Olaf Rudbeck, at that time professor of botany in the university. In the following year Rudbeck, whose advanced age compelled him to lecture by deputy, appointed Linnæus his adjunctus; in the spring of 1730, therefore, the latter began his lectures, and was accompanied by many pupils on his botanical excursions. The academic garden was entirely remodelled under his auspices, and furnished with many rare species, he being now in a position to direct the gardener, whereas in the year before he had actually solicited appointment to the vacant post of gardener, which was refused him on the ground of his capacity for better things.

His evenings were now devoted to the preparation of his epoch-making books, which were issued several years afterwards in the Netherlands. His position at the university having become unpleasant, he readily undertook to explore the little known country of Lapland, at the cost of the Academy of Sciences of Upsala. He started thence on May 12, 1732 o.s., carrying all his luggage on his back, journeying at first on horseback along the road skirting the coast to Umeå, thence by boat up the river to Lycksele within the Arctic Circle, penetrating to what he terms Olycksmýran (i.e., the unlucky marsh) in spite of the melting of the ice, which made travelling in that part almost impossible. Unable to penetrate farther into the interior, he returned to Umeå, still skirting the sea-shore by Piteå to Luleå. From this latter place he made a long excursion to the north-west by Jeckmoek and Orickmoek;

<sup>1</sup> This work has a serious mistake on both title pages; it is corrected in the errata, but the correction seems to have escaped the notice of every bibliographer.

men, crossing the mountain range, he came out upon the coast of Finmark. He retraced his steps to Luleå, and at Uleå he learned the art of assaying "in two days and a night," continuing his journey through Torneå, and the eastern coast of the gulf of Bothnia to Åbo; there he rested eight days, and finally reached Upsala by sea. The distance traversed in this tour was upwards of 4600 English statute miles; the cost of his journey is given at 112 silver dollars, or less than £25 sterling. His own account of the journey was published in English by Sir J. E. Smith, under the title *Laches Lapponica*, in 1811; the scientific results were published in his *Flora Lapponica*, Amsterdam, 1737. In 1733 Linnæus was engaged in teaching the method of assaying ores, and hoped to be allowed to lecture on botany, but a quarrel broke out between a rival, Rosen, and himself, the former having, by private influence, contrived to get a prohibition put on all private lectures on medicine in the university. Linnæus, enraged at finding his livelihood thus cut off, went so far as to draw his sword upon Rosen, but was prevented from harming his antagonist. At this juncture the governor of Dalecarlia invited Linnæus to travel through his province, as he had done through Lapland. Whilst on this journey he lectured at Fahlun to large audiences; Browallius, the chaplain there, afterwards bishop of Åbo, now strongly urged Linnæus to go abroad and take his degree of M.D. at a foreign university, by which means he could afterwards settle where he pleased. Linnæus, having become attached to the eldest daughter of Dr Moré or Moræus, left Sweden in 1735 to seek his fortune in the manner stated, and to return to claim her hand.

He travelled by Lübeck and Hamburg, detecting a seven-headed hydra to be a fabrication at the latter, he was obliged to quit the town in haste to avoid the wrath of its possessor. From Altona he went by sea to Amsterdam, staying there a week; he then proceeded to Haarlem, where he went through the requisite examination, and defended his thesis on the cause of intermittent fever. His scanty funds were now nearly spent, but he passed on through Haarlem to Leyden, there he called on Gronovius, who, returning the visit, was shown the *Systema Nature* in MS, and was so greatly astonished at it that he sent it to press at his own expense. The first edition was in eight folio sheets; the subsequent editions were in 8vo; and the twelfth immensely enlarged edition appeared during the author's lifetime. This famous system, which, artificial as it was, substituted order for confusion, largely made its way on account of the lucid and admirable laws, and comments on them, which were issued almost at the same time. See BOTANY, vol. iv. p. 80. Boerhaave, whom Linnæus saw after waiting eight days for admission, recommended him to Burman at Amsterdam, where he stayed a twelvemonth, living at the house of the professor. While there he issued his *Fundamenta Botanica*, an unassuming small octavo, which has exercised immense influence. The wealthy banker Cliffort having invited Linnæus to visit his magnificent garden at Hartecamp, he remained there, living like a prince, but working most assiduously in the garden and library, both of which were kept up without regard to cost. His *Flora Lapponica* was now printed, containing a description of the genus *Linnaea*, by his friend Gronovius; he selected this plant to bear his name, from a similarity, as he thought, between it and himself. Whilst living with Cliffort, Linnæus met with his old fellow-student Artedi, who was destitute, having spent all his money in London, Linnæus introduced him to Sebæ, then working at fishes, Sebæ's chief object of study; he worked hard at describing them, until only six remained undescribed, when he unfortunately fell into a canal at night, and was drowned.

Linnæus persuaded Cliffort to redeem the manuscript, and he published it as a memorial of his deceased friend.

In 1736 Linnæus visited England. He was warmly recommended by Boerhaave to Sir Hans Sloane, but the old collector seems to have received him coldly. A better reception awaited him at Oxford, where Dr Shaw welcomed him cordially, Dillenius, the professor of botany there, was icy at first, but afterwards thawed completely, kept him a month, and even offered to share the emoluments of the chair with him. At Chelsea he saw Philip Miller, and took some plants thence to Cliffort, but not in other stories which are current about Linnæus's visit to England are of very doubtful authenticity.

On his return to the Netherlands he completed the printing of his *Genera Plantarum*, a volume which must be considered the starting point of modern systematic botany, Tournefort formed many genera, but Linnæus was the first to circumscribe them. During the same year, 1737, Linnæus finished arranging Cliffort's collection of plants, living and dried; these were described in the *Flora Cliffortiana*, a folio illustrated with engravings by Lhret; this book was entirely written in nine months. During the compilation he used to "amuse" himself with drawing up the *Critica Botánica*, also printed in the Netherlands. But this strenuous and unceasing labour told upon him; the atmosphere of the Low Countries seemed to oppress him beyond endurance; he resisted all Cliffort's entreaties to remain with him, and started homewards.

Van Royen managed to detain him a year at Leyden, to help in rearranging the garden, thereby offending Cliffort, whom he had quitted on the plea of hastening back to Sweden. Linnæus now published his *Class. Plantarum*, and almost at the same time appeared Van Royen's *Flora Leydensis* and Gronovius's *Flora Laponica*; both of these being drawn up on the Linnæan system. In 1738 Boerhaave pressed Linnæus to accept a post at Surinam; he declined this for himself, but passed it on to John Bartsch of Königsberg, a member with himself of a select club of naturalists at Leyden. Bartsch ultimately fell a victim to the climate of that colony.

While residing at Leyden Linnæus was warned that one of his acquaintances was endeavouring to supplant him in the affections of Sara More; he intended to set out at once, but was attacked by ague before he could start. Cliffort, hearing of this, took Linnæus to his own house again, and would not suffer him to depart until he was sufficiently well. His complete recovery, however, did not take place until he had gained the higher country of Brabant, where in one day he felt himself entirely renovated. He continued his journey to Paris, where he visited Antoine and Bernard de Jussieu, forming with the latter. Abandoning all notion of returning through Germany, he went to Rouen, sailed for Sweden, and landed at Helsingborg.

Linnæus established himself in September 1738 as physician in Stockholm, but, being unknown as a medical man, no one at first cared to consult him, a great change from the attention paid to him abroad. He himself declared "that, had he not been in love, he would certainly have left his native country." By degrees he found patients, was then appointed civil physician at Stockholm, with minor appointments, and was married on the 26th June 1739.

Early in 1740 Rudbeck died, and Roberg resigned, the chairs of botany and medicine at Upsala being thus vacant, Rosen and Linnæus were chosen respectively to fill them. The former rivals afterwards agreed to exchange professorships to their mutual benefit; in 1741, previous to this exchange, Linnæus travelled through Oland and Gothland, by command of the state, publishing his results in *Olandskä och Gothlandska Resa*, 1745. The index to this volume shows the first employment of trivial names in nomenclature.

Henceforward his life was a continuous course of prosperity, his time being taken up by teaching and the preparation of other works. In the year 1745 he issued his *Flora Suecica* and *Fauna Suecica*, the latter having occupied his attention during fifteen years; afterwards, two volumes of observations made during journeys in Sweden, *Wästgöta Resa*, Stockholm, 1747,\* and *Skånska Resa*, Stockholm, 1751. He examined the collections made many years before in Ceylon by Hermann, the full publication taking place in his *Flora Zeylanica*, Stockholm, 1747. In 1748 he brought out his *Hortus Upsaliensis*, showing that he had added eleven hundred species to those formerly in cultivation in that garden. In 1750 his *Philosophia Botanica* was given to the world; it consists of a commentary on the various axioms he had published in 1735 in his *Fundamenta Botanica*, and was dictated to his pupil Löfving, while the professor was confined to his bed by an attack of gout so violent as to threaten his life; he attributed his recovery to eating plentifully of wood-strawberries, a regimen he afterwards carefully observed. A much slighter attack in the following year was mainly cured by the pleasure caused by Kalin bringing home many new plants from Canada.

He catalogued the Queen's Museum at Drottningholm, and the King's at Ulrichsdal, but the most important work of this period of his life is unquestionably his *Species Plantarum*, Stockholm, 1753,—a second edition being issued in 1762. In this volume the trivial names are fully set forth; although they had been previously shadowed forth by Linnæus and others, yet to him belongs the merit of establishing the use of a single epithet in addition to the generic name. In the same year Linnæus was created knight of the Polar Star, the first time a scientific man had been raised to that honour in Sweden.

In 1755 he was invited by the king of Spain to settle in that country, with a liberal salary, and full liberty of conscience, but he declined on the ground that whatever merits he possessed should be devoted to his country's service; Löfving was sent instead, but died within two years. He was enabled now to purchase the estates of Söfja and Hammarby; at the latter he built his museum of stone, to guard against loss by fire. His lectures at the university drew men from all parts of the world; the normal number of students at Upsala was five hundred, whilst he occupied the chair of botany there it rose to fifteen hundred. In 1761 a patent of nobility was granted, antedated to 1757, from which time Linnæus was styled Carl von Linné; his arms were those now borne by the Linnean Society of London. To his great delight the tea plant was introduced alive into Europe in 1763; this year also his son Carl was allowed to assist his father in his professorial duties, and to be trained as his successor.<sup>1</sup> At the age of sixty Linné's memory began to fail; an apoplectic attack in 1774 greatly weakened him; two years after he lost the use of his right side; and he died

10th January 1778, of an ulceration of the bladder. He was buried in the cathedral of Upsala, with every token of universal regret.

In person Linnæus was described as of medium height, with large limbs, brown piercing eyes, and acute vision, and quick-tempered. He was accustomed to sleep five hours in summer and ten in winter. He lived simply, acted promptly, and noted down his observations at the moment. His handwriting was peculiar, and not very easy to read; copies of his own books were interleaved and copiously annotated, every new discovery being posted into its proper place at once, so that new editions were readily prepared when wanted.

With him arrangement seems to have been a passion; he delighted in devising classifications; not only did he systematise the three kingdoms of nature, but even drew up a treatise on the *Genera Morborum*. He found biology a chaos; he left it a cosmos. When he appeared upon the scene, new plants and animals were in course of daily discovery in increasing numbers, due to the increase of trading facilities; he devised schemes of arrangement by which these acquisitions might be sorted provisionally, until their natural affinities should have become clearer. He made many mistakes; but the honour due to him for having first enunciated the true principles for defining genera and species, and his uniform use of trivial names, will last so long as biology itself endures. His style is terse and laconic; he methodically treated of each organ in its proper turn; he had a special term for each, the meaning of which did not vary, so that the term did not suggest two ideas at once. The reader cannot doubt the author's intention; his sentences are business-like, and to the point. The omission of the verb in his descriptions was an innovation, and gave an abruptness to his language which was foreign to the writing of his time; but it probably by its succinctness added to the popularity of his works.

By his force of character he shifted the scientific centre of gravity during his life to a small town in Sweden; he was constantly receiving presents and praise from crowds of correspondents in every civilized country and in every station of life; hence it is not surprising that this universal homage should have bred the vanity which disfigures the latter part of his diary.

No modern naturalist has impressed his own character with greater force upon his pupils than did Linnæus. He imbued them with his own intense acquisitiveness, reared them in an atmosphere of enthusiasm, trained them to close and accurate observation, and then dispatched them to various parts of the globe. His students being drawn from many quarters, he had an extensive choice; some fell victims to fatigue and unkindly climates, but there was no lack of successors. With these young enthusiasts their master's lore was like a gospel; they were eager to extend the knowledge of it, and to contribute to its richness.

The published works of Linnæus amount to more than one hundred and eighty, including the *Amanitales Academicæ*, for which he provided the material, revising them also for press; corrections in his handwriting may be seen in the Banksian and Linnean Society's libraries. His correspondence was wide and copious. Some of his letters have been published, but the bulk of them remains undated. Many works remain in MS.; some have lately been published, such as the *Flora Dalecarlica*, and the *Svenska Arbeten*, both edited by Dr Ewald Ahrling; those which were issued during the author's life are enumerated by Dr Pulteney in his *General View of the Writings of Linnæus*. (B. D. J.)

LINNELL, JOHN (1792–1882), a richly gifted English painter, was born in London on the 16th of June 1792. His father being a carver and gilder, Linnell was early brought into contact with artists, and when he was ten years old he was already drawing and selling his portraits in chalk and pencil. His first artistic instruction was received from Benjamin West, and he spent a year in the house of John Varley the water-colour painter, where he had William Hunt and Mulready as fellow pupils, and made the acquaintance of Shelley, Godwin, and other men of mark and individuality. In 1805 he was admitted a student of the Royal Academy, where he obtained medals for drawing, modelling, and sculpture. He was also trained as an engraver, and executed a transcript of the Burial of Saul, one of Varley's most impressive pictures. In after life he frequently occupied himself with the burin, publishing, in 1834, a series of outlines from Michelangelo's frescos in the Sistine chapel, and, in 1840, superintending the issue of a selection of plates from the pictures in Buckingham Palace, one of them, a Titian landscape, being mezzotinted by himself. At first he supported himself mainly by miniature painting, and by the execution

<sup>1</sup> Carl von Linné the younger, the elder son of the distinguished naturalist, was born at Fahlun, 20th January 1741. Delicate in constitution, he seemed to be oppressed with his father's reputation and his having to support it. He published two decades of new plants, and three dissertations, contributing also some descriptions to the first edition of Adon's *Hortus Kewensis*, at the time of his visit to England. He died unmarried at Upsala, 1st November 1783; and, his only brother Johan having died in infancy, the succession became extinct in the male line. His mother sold the collections and books of father and son to Dr J. E. Smith, the first president of the Linnean Society of London. When Smith died in 1828, a subscription was raised to purchase the herbarium and library for the Society, whose property they now remain. Smith sold the collection of minerals in 1796, and added many insects to the Linnean types, but the herbarium is practically in the same state as when the elder Linné himself last used it. The manuscripts of most of his publications, and the letters he received from his contemporaries, are likewise in the possession of the Society.

larger portraits, such as the likenesses of Mulready, Whately, Peel, and Carlyle. Several of his portraits he engraved with his own hand in line and mezzotint. He also painted many subjects like the St John Preaching, the Covenant of Abraham, and the Journey to Emmaus, in which, while the landscape background is usually prominently insisted upon, the figures are yet of sufficient size and importance to supply the title of the work. But it is mainly in connexion with his long series of paintings of pure landscape that his name is known to the public. When he was only seventeen, his *Removing Timber* carried off the fifty-guinea prize offered by the British Institution for the best landscape, and for many years Linnell was a regular contributor to the exhibitions of that body, and to those of the Royal Academy and the Society of Painters in Oil and Water Colours. His works commonly deal with some scene of typical uneventful English landscape, which is made impressive by a gorgeous effect of sunrise or sunset. They are full of true poetic feeling, and are rich and glowing in colour. His art proved exceptionally remunerative; he was able to command very large prices for his pictures, and about 1850 he purchased a property at Redhill, Surrey, where he resided till his death, on the 20th of January 1882, surrounded by his children—two of them artists like himself—and his children's children, and painting with unabated power till within the last few years of his life. His leisure was greatly occupied with a study of the Scriptures in the original, and he published several pamphlets and larger treatises of Biblical criticism. Among his literary productions are a work on *The Misnaming of the Scripture the Old and New Testament*, 1856; *The Lord's Day the Day of the Lord*, 1859; a pamphlet on *The Ascension Sacrifice of the Old Testament*, 1864; and one on *The Royal Academy a National Institution*, 1869. A word should be said regarding Linnell's connexion with William Blake. He was one of the best friends and kindest patrons of the great visionary artist. He gave him the two largest commissions he ever received for single series of designs—£150 for drawings and engravings of *The Inventions to the Book of Job*, and a like sum for those illustrative of Dante.

**LINNET**, Anglo-Saxon *Linete* and *Linet-wige*, whence seems to have been corrupted the old Scottish "Lintquhit," and the modern northern English "Lintwhite," originally a somewhat generalized bird's name, but latterly specialized for the *Fringilla cannabina* of Linnaeus, the *Linota cannabina* of recent ornithologists. This is a common and well-known song-bird, frequenting almost the whole of Europe south of lat. 64°, and in Asia extending to Turkestan. In Africa it is known as a winter visitant to Egypt and Abyssinia, and is abundant at all seasons in Barbary, as well as in the Canaries and Madeira. Though the fondness of this species for the seeds of flax (*Linum*) and hemp (*Cannabis*) has given it its common name in so many European languages,<sup>1</sup> it feeds largely, if not chiefly, in Britain on the seeds of plants of the order *Compositæ*, especially those growing on heaths and commons. As these waste places have been gradually brought under the plough, and improved methods of cultivation have been applied to all arable land, in England and Scotland particularly, the haunts and means of subsistence of the Linnet have been slowly but surely curtailed, and hence of late years its numbers have undergone a very visible diminution throughout Great Britain, and its diminution has also been aided by the detestable practice of netting it in spring—for it is a popular cage-bird—so popular indeed as to require no special description. According to its sex, or the season of the year, it is known as the Red, Grey, or Brown Linnet,

and by the earlier English writers on birds, as well as in many localities at the present time, these names have been held to distinguish at least two species; but there is now no question among ornithologists on this point, though the conditions under which the bright crimson-red colouring of the breast and crown of the cock's spring and summer plumage is donned and doffed may still be open to discussion. Its intensity seems due, however, in some degree at least, to the weathering of the brown fringes of the feathers which hide the more brilliant hue, and it is to be remarked that in the Atlantic islands examples are said to retain their gay tints all the year round, while throughout Europe there is scarcely a trace of them visible in autumn and winter; but, beginning to appear in spring, they reach their greatest brilliancy towards midsummer; and it is also to be remarked that they are never assumed by examples in confinement. The Linnet begins to breed in April, the nest being generally placed in a bush at no great distance from the ground. It is nearly always a neat structure composed of fine twigs, roots, or bents, and lined with wool or hair. The eggs, often six in number, are of a very pale blue marked with reddish or purplish brown. Two broods seem to be commonly brought off in the course of the season, and towards the end of summer the birds—the young of course greatly preponderating in number—collect in large flocks and move to the sea-coast, whence a large proportion depart for more southern latitudes. Of these emigrants some return the following spring, and are invariably recognizable by the more advanced state of their plumage, the effect presumably of having wintered in countries enjoying a brighter and hotter sun.

Nearly allied to the foregoing species is the Twite, so named from its ordinary call note, or Mountain Linnet, the *Linota flavirostris*, or *L. montium* of ornithologists, which can be at once distinguished by its yellow bill, longer tail, and reddish-tawny throat. This bird never assumes any crimson on the crown or breast, but the male has the rump at all times tinged more or less with that colour. In the breeding-season it seems to affect exclusively hilly and moorland districts from Herefordshire northward, in which it partly or wholly replaces the common Linnet, but is very much more local in its distribution, and, except in the British Islands and some parts of Scandinavia, it only appears as an irregular visitant in winter. At that season it may, however, be found in large flocks in the low lying countries, and as regards England even on the sea-shore. In Asia it seems to be represented by a kindred form, *L. brevirostris*.

The REDPOLES (*q.v.*) form a little group placed by many authorities in the genus *Linota*, to which they are unquestionably closely allied, but in this work they may be considered later; and, as before stated (*FINCH*, vol. xi. p. 192), the Linnets seem on the other hand to be related to the birds of the genus *Leucosticte*, the species of which, in number uncertain, inhabit the northern parts of North-West America and of Asia. The most recent list of the birds of the former country by Mr Ridgway (*Bull. U. S. Nat. Museum*, No. 21, 1881) includes four species and one local race, of which there is need here to mention only *L. tephrocotis*. It is generally of a chocolate colour, tinged on some parts with pale crimson or pink, and has the crown of the head silvery-grey. Another species, *L. arctica*, was formerly said to have occurred in North America, but its proper home is in the Kurile Islands or Kamchatka. This has no red in its plumage. The birds of the genus *Leucosticte* seem to be more terrestrial in their habit than those of *Linota*, perhaps from their having been chiefly observed where trees are scarce; but it is possible that the mutual relationship of the two groups is more apparent than real. Allied to *Leucosticte* is *Montifringilla*

<sup>1</sup> *L. l.*, French, *Linotte*; German, *Hänfling*; Swedish, *Hänfling*.

to which belongs the Snow-Finch of the Alps, *M. nivalis*, so often mistaken by travellers for the Snow-Bunting, *Plectrophanes nivalis*. (A. N.)

**LINOLEUM** is a kind of floor-cloth, invented and introduced by Mr F. Walton, who in 1860 obtained a patent for its manufacture. It consists of a preparation of linseed oil and ground cork intimately mixed and spread in a uniform layer over a sheet of rough jute canvas. Under the name of kamptulicon, a material similar in appearance and properties, but in which prepared india-rubber took the place of oxidized linseed oil, was in use to a limited extent previous to the introduction of linoleum; the latter material, however, was found to possess several advantages; among others it had the merit of comparative cheapness as against kamptulicon, which it entirely supplanted. Linoleum also became a formidable competitor with the old form of oil floor-cloth, and on the expiry of Mr Walton's patent the manufacture of the new material was very generally taken up in Kirkealdy, the principal seat of the floor-cloth trade. In the hands of Messrs Michael Nairn & Co., who were the first to introduce the floor-cloth industry into Scotland, the machinery used for making linoleum has been improved in important respects, and the ingenuity and resource of Mr Walton, the original patentee, have discovered several new adaptations and modifications of his original invention.

The making of linoleum involves three distinct preliminary operations: (1) the oxidation of the linseed oil, (2) the grinding of the cork, and (3) the weaving of the jute canvas backing. Of these operations the oxidation of the oil is the most peculiar and distinctive. The linseed oil is first boiled with litharge in the way practised for preparing ordinary boiled oil (see **LINSEED**), and it is next oxidized by exposure, in exceedingly thin films, to the influence of air. To secure the exposure of sufficient surfaces of oil to the atmosphere, a large lofty apartment is hung with sheets or continuous webs of calico cloth, which are allowed to depend from near the roof into troughs or tanks on the floor. These webs of calico are kept sufficiently far apart to allow free circulation of air between them. They are daily drenched with boiled oil by allowing it to trickle down from the top over their entire surface, the distribution being effected by a special arrangement of movable tanks and tubs. It will be seen that an enormous surface of oil can thus be exposed within a comparatively limited space. The influence of oxygen on the oil films is facilitated by the blowing of heated air into the chamber so as to keep up a continual circulation; and the activity of the process is unpleasantly manifested by the extremely acrid odour which is evolved by the oil. Day by day the thickness of the coating of oxidized oil increases, and when a deposit of about half an inch has been accumulated, the drenching is stopped. The product, now ready for being withdrawn, forms firm translucent sheets of a caoutchouc-like substance having a straw yellow colour, possessed of a certain amount of elasticity, and communicating no oily stain to paper. These sheets are now torn into small pieces and reduced to a uniform plastic mass by means of powerful crushing rollers, after which the material is placed in a close boiler with the addition of certain proportions of kawrie gum, rosin, and ochre, umber, or other pigment, according to the ground-colour desired. The boiler is heated by steam, and the entire mass, being thoroughly incorporated by means of stirrers, is run into a shallow trough, from which, after cooling and solidifying, it is taken in large slabs. These are piled up awaiting future use, and when required for manufacturing purposes they are cut into blocks about the size of an ordinary brick.

Ground cork, which is the second essential constituent of linoleum, may be made from cork cuttings and scraps;

but, the supply of such material being unequal to the demand, bale cork, of secondary quality as imported, is very largely used. It is first broken to pieces about the size of a nut; the fragments are fed into the hopper of a mill; and the cork passes thence between a pair of ordinary millstones in which it is reduced to a meal-like condition, in exactly the same way as wheat is ground to flour. The product is sifted, and the insufficiently ground portions are returned to be passed again through the mill. In the grinding of the cork great care is necessary to prevent iron, stone, or other hard foreign material from getting into the mill, as such substances, causing sparks between the stones, readily give rise to explosions in air so laden with fine dust as that of the mill necessarily is.

In the making of the jute backing the only notable feature is the great width of the loom, in which webs 12 feet broad are woven by Messrs Nairn. The maximum width of that produced by other makers, however, has hitherto been 6 feet.

The actual preparation of linoleum floor-cloth in the factory of Messrs Nairn is conducted in a continuous series of operations by machinery which has been patented by that firm. The bricks of oxidized oil and the requisite proportion of cork are thrown into a hopper, where they are thoroughly mixed in a kind of pug mill, whence the mixture is shot forward in a tube, at the open end of which it is sliced off in thin crumbling masses by a revolving knife. Spread out in thin sheets, it passes from this between a series of steam-heated rollers, from the last of which it is scratched off by a circular drum covered with sharp steel points, and falls in a fine shower into a feeding box the whole width of the linoleum to be made. From this feeding box the mixture is uniformly delivered on the surface of the canvas, which here meets it, and passing immediately between powerful smooth rollers, the semi-plastic mixture is firmly squeezed on the surface of, and rendered adherent to, the rough open canvas which forms its back. The distance between the upper and lower compressing roller determines the thickness of the linoleum, three standard thicknesses being recognized, viz.,  $\frac{3}{32}$ ,  $\frac{1}{8}$ , and  $\frac{1}{4}$  parts of an inch. Linoleum of the thickness of  $\frac{1}{4}$  of an inch is also made for public libraries and reading-rooms on account of its perfect noiselessness. It only remains to coat or waterproof the raw canvas back with oil paint, and the floor-cloth is finished as plain linoleum. The printing of patterns in various colours on its surface is done as described under **FLOOR-CLOTH**, vol. ix. p. 329. Corticine is a form of linoleum, in which the oil is oxidized by chemical agents.

Recently a method of ornamenting linoleum with patterns in the form of tiles or tesserae, the colour of each tile going right through to the canvas or sufficiently deep for constant wear, has been devised and patented by Mr C. F. Leake. The patentee prefers to use canvas first covered with a thin linoleum coating. This he brings on a table on which are a series of moulds corresponding with the coloured tile pattern required. Into each mould is put the required quantity of properly coloured granulated linoleum material, which is compressed into solid tiles by the descent of plungers. The part covered by the pattern is carried forward and powerfully squeezed between hydraulic rams, the tiles being thus made smooth, homogeneous, and firmly adherent, while in the meantime the moulds are being filled and a new set of tiles prepared in the first stage of the operation. Mr Walton, the original patentee of linoleum, has adapted a preparation of oxidized oil and cork or other thickening material embossed with patterns for wall decorations under the name of "Linerusta Walton." (J. PA.)

**LINSEED** is the seed of the common flax or lint, *Linum usitatissimum*, from which also the well-known fibre flax is obtained. The plant itself is figured and described under **FLAX**, vol. ix. p. 293. The fruit of the flax plant consists of a globose capsule, which splits into five cocci, each containing two seeds. These seeds, the linseed of commerce, are of a lustrous brown colour externally, and a

compressed and elongated oval form, with a slight beak or projection at one extremity. The brown testa contains, in the outer of the four coats into which it is microscopically distinguishable, an abundant secretion of mucilaginous matter; and it has, within it a thin layer of albumen, enclosing a pair of large oily cotyledons. The seeds when placed in water for some time become coated with glutinous matter from the exudation of the mucilage in the external layer of the epidermis; and by boiling in sixteen parts of water they exude sufficient mucilage to form with the water a thick pasty decoction. The cotyledons contain the valuable linseed oil referred to below. Linseed grown in tropical countries is much larger and more plump than that obtained in temperate climes, but the seed from the colder countries, on the other hand, yields a finer quality of oil. Flückiger and Hanbury found that six seeds of Sicilian linseed, thirteen of Black Sea, and seventeen of Archangel linseed weighed respectively one grain. The average composition of linseed may be fairly represented by the following analysis by Dr Thomas Anderson:—albuminous substances, 24.44; oil, 34.00; gum sugar and cellulose, 30.73; ash, 3.33; water, 7.50. Linseed is cultivated and secured as a crop in all European flax-growing countries, where the seed is probably not less valuable than the fibre. It is also obtained from Egypt and India, being cultivated in the latter country solely on account of the seed.

Apart from its value as a source of oil, and for sowing, linseed is not a product of much economic importance. It formed an article of food among the Greeks and Romans, and it is said that the Abyssinians at the present day eat it roasted. The oil is to some extent used as food in Russia, and in parts of Poland and Hungary. Linseed meal, partly on account of its bland oily constitution, is a valuable material for poultices. At one time the crushed seeds were the officinally recognized cataplasmic material, but the readiness with which that preparation became rancid through the oxidation of its abundant oil frequently rendered it a dangerous application for open sores. The *lini farina* of the pharmacopœia is now the powdered meal of the cake left after expression of the oil, with a proportion of olive oil added when about to be used. An infusion of linseed under the name of "linseed tea" is a popular diluent in bronchial and other inflammatory affections. The abundant mucilage in linseed meal makes it a most useful material for luting stoppers in chemical jars, and other such joints in glass-work. Linseed cake, the meal left after the expression of the oil, is a most valuable feeding substance for cattle. According to a recent analysis by Dr Voelcker (*Journ. Roy. Agric. Soc.*, 2d ser., vol. xvii. p. 659) it contains in 100 parts—oil, 10.90; albuminous compounds, 24.56; mucilage, sugar, and digestible fibre, 31.97; woody fibre, 11.47; ash, 6.20; moisture, 14.90.

Linseed is subject to extensive and detrimental adulterations, resulting not only from careless harvesting and cleaning, whereby seeds of the flax dodder and other weeds and grasses are mixed with it, but also from the direct admixture of cheaper and inferior oil seeds, such as wild rape, mustard, sesame, poppy, &c., the latter adulterations being known in trade under the generic name of "buffum." In 1884, owing to the serious aspect of the prevalent adulteration, a union of traders was formed under the name of the "Linseed Association," the members of which bind themselves to give compensation for all adulterations in excess of 4 per cent. of foreign matter. Highly adulterated linseed is, however, still very common outside the field of operations of the Linseed Association.

The quantity of linseed imported into the United Kingdom during the year 1881 was 1,829,838 quarters, of a value of £4,395,061. About one-half of this amount, 937,059 quarters, valued at £2,399,877, came from the East Indies, and the imports from Russia, amounting to 728,358 quarters, valued at £1,694,720, account for the greater part of the remainder.

**Linseed Oil**, the most valuable and characteristic of the series of drying oils, is obtained by expression from the seeds with or without the aid of heat. Preliminary to

the operation of pressing, the seeds are crushed between a pair of revolving rollers, and ground to a fine meal under heavy edge stones on a stone bed. For the extraction of the fine quality of oil known as cold-drawn the meal is, without further preparation, filled into woollen or canvas bags and enclosed in horse-hair envelopes for pressure, either in a Dutch mill worked by means of wedges and falling stampers or in a screw press, or, what is now more prevalent, in a special form of hydraulic press. The oil so obtained is of a clear yellow colour, and is comparatively devoid of odour and taste. The cake left by cold pressure is again ground up, heated in a steam kettle to about 212° Fabr., and while hot submitted to further pressure, which results in the exudation of a less pure oil of a brownish-yellow colour. In general practice, cold-drawn oil is little prepared; the linseed after grinding is submitted to a high heat, whereby the mucilage in the epidermis is destroyed, and the oil flows more freely, and in many crushing establishments the oil is obtained by a single operation under the press. The yield of oil from different classes of seed varies, but from 23 to 28 per cent. of the weight of the seed operated on should be obtained. A good average quality of seed weighing about 392 lb per quarter has been found in practice to give out 109 lb of oil.

Commercial linseed oil has a peculiar rather disagreeable sharp taste and smell; its specific gravity is given as varying from 0.928 to 0.953, and it does not solidify under the influence of very low temperature. It is soluble in 32 parts of alcohol, sp. gr. 0.82, in 6 parts of boiling alcohol, and in 1.6 of ether. By saponification it yields about 95 per cent. of fatty acids, principally linoleic acid ( $C_{18}H_{32}O_2$ ), a body peculiar to the drying oils, and by treatment with oxide of lead about nine-tenths of the resulting lead salt is found to be linoleate of lead. The oil may be perfectly bleached by treatment with a solution of green sulphate of iron, with repeated shaking and exposure to the light for a period of four to six weeks. Exposed to the air in thin films, linseed oil absorbs oxygen and forms a resinous semi-elastic caoutchouc-like mass, oxylinoleic acid,  $C_{18}H_{30}O_3$ . The oil, when boiled with small proportions of litharge and minium, undergoes the process of resinification in the air with greatly increased rapidity. Sarc found by boiling 2500 grains of raw oil for ten minutes with 30 grains each of litharge and minium, and weighing after twenty-four hours exposure to the atmosphere, that the oil had lost only 60 grains. A second sample he boiled till there was a loss of 5 per cent. in weight, when the product assumed the consistency of molasses; and a third portion boiled to a loss of 12 per cent. became a caoutchouc-like mass. The first of these products he found dried, on exposure, to a fine transparent varnish; the second did not resinify after fifteen days' exposure; and the atmosphere had no effect on the third portion. The weight of the film of the first after complete resinification was increased 50 per cent. through absorption of oxygen, and the rate at which absorption took place was much influenced by heat.

To these physical properties the varied industrial applications of linseed oil are principally due. Its most important use is certainly found in the preparation of oil paints and varnishes. By painters both raw and boiled oil are used, the latter not only forming the principal medium in oil painting, but also serving separately as the basis of all oil varnishes. Boiled oil is prepared in a variety of ways—that most common being by heating the raw oil in an iron or copper boiler, which, to allow for frothing, must be about three-fourths filled. The boiler is heated by a furnace, and the oil is brought gradually to the point of ebullition, at which it is maintained for two hours, during which time moisture is driven off, and the scum and froth which accumulate on the surface are baled out. Then by slow degrees a proportion of "driers" added—usually equal weights of litharge and minium bent to the extent of 3 per cent. of the charge of oil, and with these a small proportion of amber is generally thrown in. After the addition of the driers the boiling is continued two or three hours;

the fire is then suddenly withdrawn, and the oil is left covered up in the boiler for ten hours or more. Before sending out, it is usually stored in settling tanks for a few weeks, during which time the uncombined dryers settle at the bottom as "foots." Besides the dryers already mentioned, acetate of lead, borate of manganese, binocide of manganese, sulphate of zinc, and other bodies are used. The theory of the influence of boiling and of the addition of these bodies on linseed oil is not well understood. By Liebig it was suggested that they simply removed the mucilaginous and other foreign constituents of the oil which by their presence intercepted the action of oxygen; but by Chevreul and others the opinion was held that the chemicals used, by giving up oxygen to the oil, thereby induce a more rapid and energetic absorption from the air. However this may be, it does not appear at least that boiling is essential for the production of that active condition of the oil, as it may also be induced by treatment of cold raw oil with lead acetate and other agencies. Boiled oil is now very largely used in the manufacture of linoleum floor-cloth. See LINOLEUM.

Linseed oil is also the principal ingredient in printing and lithographic inks. The oil for ink-making is prepared by heating it in an iron pot up to the point where it either takes fire spontaneously or can be ignited with any flaming substance. After the oil has been allowed to burn for some time according to the consistence of the varnish desired, the pot is covered over, and the product when cooled forms a viscid tenacious substance which in its most concentrated form may be drawn into threads. By boiling this varnish with dilute nitric acid vapours of acrolein are given off, and the substance gradually becomes a solid non-adhesive mass the same as the ultimate oxidation product of both raw and boiled oil.

Linseed oil is subject to various fabrications, which through the addition of cotton seed, rapeseed, and hempseed oils; and in an oil and mineral oils also or not infrequently alcohol. Except by smell, by change of specific gravity, and by determination of drying properties, these adulterations are difficult to detect. (cf. F.A.)

LINUS is one of a numerous class of heroic figures in Greek legend, of which other examples may be found under HYACINTHUS, ADONIS. The connected legend is always of the same character: a beautiful youth, fond of hunting and rural life, the favourite of some god or goddess, suddenly perishes by a terrible death in spite of the heavenly love that would fain protect him. In some cases nothing is known to us with certainty beyond the mythological figure, but in many cases the religious background from which the legend stands out in relief has been preserved to us; in such cases we see that an annual ceremonial, everywhere of the same enthusiastic character, commemorated the legend. At Argos this religious character of the Linus myth was best preserved; the secret child of Peramthe by the god Apollo, Linus is exposed, reared by sheep, and torn in pieces by the sheep-dogs. Every year in the festival Anis or Cynophontis, the women of Argos mourned for Linus and propitiated Apollo, who in revenge for his child's death had sent a plague on the Argive children. The grave of Linus, like that of Hyacinthus at Anagly, was shown at Argos, at Thebes, at Chalcis, and probably at other places. The enthusiasm and abandon which characterized the annual festivals over Greece, Asia Minor, and Syria prove that it was part of the native worship which spread in various forms by different roads and at different periods from the East to Greece. The song of lamentation which accompanied the festival strongly impressed the Greeks, and it is most probable that the Phœnician words *adon*, *adonis*, which formed the burden of the Adonis songs, originated the Greek words *Linus* and *Adon*. The Linus song is frequently mentioned in Greek literature, Homer, *Il.* xvi. 599; Pind., *P.* 139 (Bergk), &c.; the tragic poets often use the word *Adon* as the refrain in mournful songs, and Euripides calls the custom Phrygian (*Or.* 1349). In Phrygia the mythic correspondent of Linus is called *Lityeres*. There can be no doubt that Linus, Adonis, Maneris, Narcissus, &c., are personifications of the life and bloom of nature suddenly slain by the hot sun of summer, while with the religious mourning over the catastrophe of nature were intertwined the ideas of life in relation to death, of good and evil, and so on. The religious side of the Linus myth seems hardly to have

existed in Greece outside of Argos; in Thebes, which also was a chief home of the legend, Linus was a hero of song and music. In this form he has passed into literature, e.g., Virgil, *Ecl.* vi. 67. He is conceived as the inventor of musical methods, especially of the *Op̄nos*, a kind of lament; this idea was expanded in various ways, particularly by the Alexandrine poets; and finally he was, after the analogy of Musæus, transformed into a composer of prophecies and legends.

See Brugsch, *Die Adonis Klage und das Linos Lied*, &c.

LINUS, one of the saints of the Gregorian canon, was, according to the *Breviarium Romanum*, the immediate successor of Peter in the see of Rome. He was a native of Volterra, who had attained a high degree of sanctity, and by his prevailing faith was able, not only to cast out devils, but to raise the dead. He wrote an account of the *res gestæ* of Peter, especially of his controversy with Simon Magus. He was beheaded by the orders of the ungrateful consul Saturninus, whose daughter he had freed from demoniac possession, after a pontificate of eleven years two months and twenty-three days. The authorities for the statement that Linus was, leaving Peter out of account, the earliest president of the Roman Church, are very early (Irenæus, *Adv. Hær.* iii. 3, 3; Euseb., *H. E.* iii. 2, 13); and that there actually was a presbyter of that name may be gathered from 2 Tim. iv. 21. According to Tertullian, however (*De Præscr.* 32), Peter appointed Clement to be his successor. The genuineness of the alleged epitaph of Linus found in Rome is now no longer maintained; and the two books on the martyrdom of Peter and Paul, which pass under his name, must also be regarded as apocryphal and late.

LINZ, capital of Upper Austria, and see of a bishop, in 48° 19' N. lat., 14° 16' E. long., lies upon the right bank of the Danube, 98 miles west of Vienna, at the junction of the Kaiserin-Elizabeth Western Railway with a line from Prague and Budweis. The market-town of Urfahr, on the opposite side of the river, is connected with the city

Plan of Linz.

by an iron bridge 700 feet in length, constructed in 1872. Linz possesses two cathedrals, one dating from 1670, and another, dedicated to the Immaculate Conception, commenced in 1862, and still unfinished, a Lutheran (1845) and several Roman Catholic churches, the new synagogue opened in 1877, and many religious houses. The old

**Landeshaus, or House of the Estates (1562), the Bibliotheca Publica (1788), now (1882) containing 34,000 volumes, the Museum Franciscus-Carolinum (1834), and a state theatre (1803) may also be noticed, with the episcopal and archducal palaces, and the castle now used as barracks.** There are many educational establishments, including the theological diocesan lyceum, a new gymnasium and normal schools, and several hospitals and asylums. The principal manufactures are of tobacco (in 1880 employing 787 hands, and producing 25,286,050 cigars and 1850 tons of tobacco), and boot-varnish and blacking (2500 cwt.), the last chiefly exported to Hungary and Italy. Two breweries in 1881 produced 1,781,828 gallons of beer, and the other industries include iron-boat-building, and the manufacture of locomotives and agricultural implements. Trade and commerce are facilitated by the river. About forty six thousand passengers embark or disembark at the steamboat landing stage, and the imports and exports there amount together to about 500,000 cwt. annually. There is a considerable traffic in woollen goods, carpets, linen fabrics, thread, prepared leather, iron wares, and salt. Cattle and meat markets are held twice a week. The Volksfest, a popular fair held generally every second September, is much resorted to by strangers. The surrounding country is highly picturesque. On the 31st December 1880 the population (exclusive of the garrison, 2739) was 36,116, or with the suburbs of Waldegg (1204) and Lustenau (1568) 38,888, chiefly Roman Catholics.

Linz is believed to stand on the site of the Roman station *Lentum* or *Lentia*. The authentic history of Linz cannot be traced farther back than 799. In 1140 it was purchased from Gerd Chalk, count of Kyrnberg, by Leopold IV., margrave of Austria; in 1324 it first received municipal rights, and in 1490 became the capital of the province above the Enns. Of various attacks which Linz from time to time successfully resisted the most notable was that by the insurgent peasants under Stephen Fadinger, 21st and 22d July 1626, when the suburbs were laid in ashes. At Linz (16th December 1645) peace was concluded between the emperor Ferdinand III. and the Transylvanian prince Rakoczy (see HUNGARY, vol. xii. p. 370). During the siege of Vienna in 1683 the castle at Linz was the residence of Leopold I. The triple deliverance of Linz from war, fire, and pestilence was commemorated by Charles VI. in 1723, by the erection of a marble monument known as Trinity Column. In 1741, during the war of the Austrian succession, Linz was taken by the troops of the elector of Bavaria, but on the 23d January 1742 it was recovered by the Austrians. The bishopric was established by Pope Pius VI. in 1781. On the 15th of August 1800 many of the principal buildings were destroyed by fire. On the 17th May 1809 an Austrian force was defeated near the city in an engagement with Saxon and Württemberg troops. The chain of outlying forts, thirty-two in number, now abandoned, and to a great extent demolished, was constructed between 1828 and 1836 under the direction of Archduke Maximilian d'Este. A general assembly of the Catholic Union for Germany was held here 24th to 26th September 1850. Tramways were introduced in 1880, and a new line of railway through the Krensthäl was completed as far as Krensmünster in 1881.

See the anonymous *Führer auf der Krensthalbahn, mit Beschreibung von Linz*, Linz, 1881; the *Statistischer Bericht Oberösterreichs 1876-1880*, Linz, 1881, vol. ii. pp. 243-283; the official *Ergebnisse über die Volkszählung in Linz*, Linz, 1881; F. **LION.** From the earliest historic times few animals have been better known to man than the lion. Its geographical habitat made it familiar to all the races among whom human civilization took its origin, and its strongly marked physical and moral characteristics have rendered it proverbial, perhaps to an exaggerated degree, and have in all ages afforded favourite types for poetry, art, and heraldry.

The literature of the ancient Hebrews abounds in allusions to the lion; and the almost incredible numbers that are stated to have been provided for exhibition and destruction in the Roman amphitheatres (as many as six hundred on a single occasion by Pompey, for example) show how abundant these animals must have been within accessible distance of the capital of the world.

The geographical range of the lion was once far more extensive than at present, even within the historic period covering the whole of Africa, the south of Asia, including Syria, Arabia, Asia Minor, Persia, and the greater part of northern and central Hindustan, and also the south-eastern portion of Europe, as shown by the well known story told by Herodotus of the attacks by lions on the camels which carried the baggage of the army of Xerxes on its march through the country of the Paonians in Macedonia. The very circumstantial account of Herodotus shows that the animal at that time ranged through the country south of the Balkans, through Bournium to the west of the river Carasus, and through Thessaly as far south as the Gulf of Lepanto and the Isthmus of Corinth, having as its western boundary the river Potamo and the Pindus mountains. The whole of the evidence relating to the existence of lions in Europe, and to their retreat from that continent shortly before the commencement of the Christian era, has been collected in the article on "*Felis spelæa*" in Boyd Dawkins and Sanford's *British Pleistocene Mammalia*, 1878. Fossil remains attest a still wider range, as it is shown in the same work, that there is absolutely no osteological or dental character by which the well known cave lion (*Felis spelæa* of Goldfuss), so abundantly found in cave deposits of the Pleistocene age, can be distinguished from the existing *Felis leo*. There are also remains found in North America of an animal named *Felis atrox* by Leidy, which the paleontologists just quoted attribute to the common lion; but, as they are very fragmentary, and as the specific characters by which most of the *Felide* are distinguished are more dependent on external than on anatomical conformation, this determination cannot be so absolutely relied upon.

At the present day the lion is found in localities suitable to its habits, and where not exterminated (as it probably was in Europe) by the encroachments of man, throughout Africa from Algeria to the Cape Colony, and in Mesopotamia, Persia, and some parts of the north-west of India. According to Blanford, lions are still very numerous in the reedy swamps bordering the Tigris and Euphrates, and also occur on the west flanks of the Zagros mountains and the oak clad ranges near Shiraz, to which they are attracted by the immense herds of swine which feed on the acorns. The lion nowhere exists in the table land of Persia, nor is it found in Baluchistan. In India it appears now to be confined to the province of Kathiawar in Gujerat, though within the present century its range extended through the north-west parts of Hindustan, from Bahawalpur and Sind to at least the Jumna (about Delhi), southward as far as Khanda-h, and in Central India through the Sagur and Nerbudda territories, Bundelkund, and as far east as Palamau. It was exterminated in Huiiana about 1821. One was killed at Rhyb, in the Dumaoh district, Sagur and Nerbudda territories, so late as in the cold season of 1847-48; and about the same time a few still remained in the valley of the Sind river in Kotah, Central India (Rhyb).

The great variations in external characters which different lions present, especially in the colour and the amount of mane, has given rise to the idea that there are several species, or at all events distinct varieties peculiar to different localities. It was at one time supposed, on the authority of Captain Walter Smeeth, that the lion of Gujerat differed essentially from that of Africa in the absence of mane, but subsequent evidence has not supported this view, which was probably founded upon young specimens having been mistaken for adults. Lions from that district as well as from Babylon, which have lived in the gardens of the London Zoological Society, have had

<sup>1</sup> *Zoology and Geology of Eastern Persia*, 1876.

<sup>2</sup> *Transactions of the Zoological Society*, vol. i. p. 165, 1835.

fully developed manes as any other of the species. Mr F. C. Selous<sup>1</sup> has shown that in South Africa the so-called black-maned lion and others with yellow scanty manes are found, not only in the same locality, but even among individuals of the same parentage.

The lion belongs to the very natural and distinctly defined group constituting the genus *Felis* of Linnæus (for the characters and position of which see article MAMMALIA), a genus held by Pallas and other philosophical naturalists as a model of what a genus ought to be, although recent writers have divided and subdivided it into as many as thirteen sections, on each of which a new generic term has been imposed. Among these sections is one containing the largest members of the group, and differing from the others in the well-marked anatomical character that the anterior cornu of the hyoid arch is but little ossified, and by the less important one that the pupil of the eye when contracted is a circular hole, instead of a vertical slit as in the cat. The lion agrees with the tiger and the leopard in these respects, but differs from them in its uniform style of colouring, and from all the other *Felide* in the arrangement of its hairy covering, the hair of the top of the head, chin, and neck, as far back as the shoulder, being not only very much longer, but also differently disposed from the hair elsewhere, being erect or directed forwards, and so constituting the characteristic ornament called the mane. There is also a tuft of elongated hairs at the end of the tail, one upon each elbow, and in most lions a copious fringe along the

plain-coloured species of deer show for a time the light-coloured spots which are met with in the adults of only some of the species. The usual colour of the adult lion is yellowish-brown, but it may vary from a deep red or chestnut brown to an almost silvery grey. The mane, as well as the long hair of the other parts of the body, sometimes scarcely differs from the general colour, but it is usually darker and not unfrequently nearly black. The mane begins to grow when the animal is about three years old, and is fully developed at five or six.

In size the lion is only equalled or exceeded by the tiger among the existing *Felide*; though both species present great variations, the largest specimens of the latter appear to surpass the largest lions. A full-sized South African lion, according to Selous, measures slightly less than 10 feet from nose to tip of tail, following the curves of the body. Harris gives 10 feet 6 inches, of which the tail occupies 3 feet. The lioness is about a foot less.

The internal structure of the lion, except in slight details, resembles that of the other *Felide*, the whole organization being that of an animal modified to fulfil, in the most perfect degree yet attained, an active, predaceous mode of existence. The teeth especially exemplify the carnivorous

FIG. 1.—Lion. A Drawing by Wolf in Elliot's Monograph of the *Felide*.

FIG. 2.—Front View of Skull of Lion.

type in its highest condition of development. The most important function they have to perform, that of seizing and holding firmly animals of considerable size and strength, violently struggling for life, is provided for by the great, sharp-pointed, and sharp-edged canines, placed wide apart at the angles of the mouth, the incisors between them being greatly reduced in size and kept back nearly to the same level, so as not to interfere with their action. The jaws are short and strong, and the width of the zygomatic arches, and great development of the bony ridges on the skull, give ample space for the attachment of the powerful muscles by which they are closed. In the molar series of teeth the sectorial or scissor-like cutting function is developed at the expense of the tubercular or grinding, there being only one rudimentary tooth of the latter form in the upper jaw, and none in the lower. They are, however, sufficiently strong to break bones of large size. The dental formula is expressed as follows:—incisors  $\frac{2}{2}$ , canines  $\frac{1}{1}$ , premolars  $\frac{2}{2}$ , molars  $\frac{4}{4}$ ; total, 30. The tongue is long and flat, and remarkable for the development of the papillae of the anterior part of the dorsal surface, which (except near the edge) are modified so as to resemble long, compressed, recurved, horny spines or claws, which, near the middle line, attain the length of one-fifth of an inch. They give the part of the tongue on which they occur this appearance and feel of a coarse rasp, and serve the purpose of such an instrument in cleaning the flesh from the bones of the animals on which the lion feeds. The yankal

middle line of the under surface of the body, wanting, however, in some examples." It must, however, be observed that these characters are peculiar to the adults of the male sex only, and that, even as regards their coloration, young lions show indications of the darker stripes and mottlings so characteristic of the greater number of the members of the genus; just as the young of nearly all the

<sup>1</sup> A Hunter's Wanderings in Africa, 1881, p. 258.

Mr Selous, who undertook, for obtaining evidence upon this subject were very large, say that in the region of South Africa, between the Zambesi and the Limpopo rivers he never saw a lion with any long hair under the body, and that the manes of the wild lions of that district are far inferior in development to those commonly seen in species in Europe.

column is composed of seven cervical, thirteen dorsal, seven lumbar, three sacral, and about twenty-six caudal vertebrae. The clavicles are about 3 inches in length, embedded loosely in the muscles, and not directly connected either with the sternum or the scapula. The limbs are digitigrade, the animal resting upon round soft pads or cushions covered with thick, naked skin, one on the under surface of each of the principal toes, and one larger one of trilobed form, behind these, under the lower ends of the metacarpal and metatarsal bones, which are placed nearly vertically in ordinary progression. The fore feet have five toes, of which the third and fourth are nearly equal and longest, the second being slightly and the fifth considerably shorter. The first or pollex (corresponding to the human thumb) is much shorter than the others, and does not reach to the ground in walking. The hind feet have only four toes, the third and fourth being the longest, the second and fifth somewhat shorter and nearly equal. The first or hallux (or great toe) is represented only by a rudimentary metatarsal bone. The claws are all very large, strongly compressed, very sharp, and exhibit the retractile condition in the highest degree, being drawn backwards and upwards into a cutaneous sheath by the action of an elastic ligament so long as the foot is in a state of repose, but exerted by muscular action when the animal strikes its prey. By this remarkable piece of animal mechanism their edges and points are always kept sharp and unworn.

The habits of the lion in a state of nature are fairly well known from the united observations of numerous travellers and sportsmen who have explored those districts of the African continent in which it is still common. It lives chiefly in sandy plains and rocky places interspersed with dense thorn-thickets, or frequents the low bushes and tall rank grass and reeds that grow along the sides of streams and near the springs where it lies in wait for the larger herbivorous animals on which it feeds. Although it is occasionally seen abroad during the day, especially in wild and desolate regions, where it is subject to but little molestation, the night is, as in the case of so many other predaceous animals, the period of its greatest activity. It is then that its characteristic roar is chiefly heard, as thus graphically described by Gordon Cumming:—

"One of the most striking things connected with the lion is his voice, which is extremely grand and peculiarly striking. It consists at times of a low deep moaning, repeated five or six times, ending in faintly audible sighs; at other times he startles the forest with loud, deep-toned, solemn roars, repeated in quick succession, each increasing in loudness to the third or fourth, when his voice dies away in five or six low muffled sounds very much resembling distant thunder. At times, and not unfrequently, a troop may be heard, roaring in concert, one assuming the lead, and two, three, or four more regularly taking up their parts, like persons singing a catch. Like our Scottish stags at the rutting season, they roar loudest in cold frosty nights; but on no occasions are their voices to be heard in such perfection, or so intensely powerful, as when two or three troops of strange lions approach a fountain to drink at the same time. When this occurs, every member of each troop sounds a bold roar of defiance at the opposite parties; and when one roars, all roar together, and each seems to vie with his comrades in the intensity and power of his voice. The power and grandeur of these nocturnal concerts is inconceivably striking and pleasing to the hunter's ear."

"The usual pace of a lion," C. J. Andersson<sup>1</sup> says, "is a walk, and, though apparently rather slow, yet, from the great length of his body, he is able to get over a good deal of ground in a short time. Occasionally he trots, when his speed is not inconceivable. His gallop—or rather succession of bounds—is, for a short distance, very fast,—nearly or quite equal to that of a horse. Indeed, unless the steed has somewhat the start when the beast charges, it will be puzzled to escape. Many instances are on record of horsemen who have incautiously approached too near to

the lion, prior to firing, who have been pulled down by him before they could get out of harm's way. Happily, however, the beast soon tires of the exertion of galloping, and unless his first rush succeeds he, for the most part, soon halts and beats a retreat." "The lion, as with other members of the feline family," the same writer tells us, "seldom attacks his prey openly, unless compelled by extreme hunger. For the most part he steals upon it in the manner of a cat, or ambushes himself near to the water, or a pathway frequented by game. At such times he lies crouched upon his belly in a thicket until the animal approaches sufficiently near, when, with one prodigious bound, he pounces upon it. In most cases he is successful, but should his intended victim escape, as at times happens, from his having miscalculated the distance, he may make a second or even a third bound, which, however, usually prove fruitless, or he returns disconcerted to his hiding-place, there to wait for another opportunity." His food consists of all the larger herbivorous animals of the country in which he resides,—buffaloes, various kinds of antelopes, zebras, giraffes, or even young elephants or rhinoceroses, though the adults of these latter he dare not attack. In cultivated districts the cattle, sheep, and even human inhabitants are never safe from his nocturnal ravages. He appears, however, as a general rule, only to kill when hungry or attacked, and not for the mere pleasure of killing, as with some other carnivorous animals. He, moreover, by no means limits himself to animals of his own kind, but, according to Selous, often prefers eating game that has been killed by man, even when not very fresh, to taking the trouble to catch an animal himself. All books of African travel and sport abound with stories, many of which are apparently well authenticated, of the lion's prodigious strength, as exemplified by his being able to drag off a whole ox in his mouth to a long distance, even leaping fences and dykes with it.

The lion appears to be monogamous, a single male and female continuing attached to each other irrespectively of the pairing season. At all events the lion remains with the lioness while the cubs are young and helpless, and assists in providing her and them with food, and in educating them in the art of providing for themselves. The number of cubs at a birth is from two to four, usually three. They are said to remain with their parents till they are about three years old. The following account by an eyewitness gives a good idea of lion family life:—

"I once had the pleasure of, and saved myself, watching a lion family feeding. I was encamped on the Black Embos in Zululand, and toward evening, working out, about half a mile from camp, I saw a herd of zebra galloping across my, and when they were nearly 200 yards off, I saw a yellow body flash towards the herd, and saw him fall beneath the lion's weight. There was a tall tree about 60 yards from the place, and anxious to see what went on, I stalked up to it, while the lion was still too much occupied to look about him, and climbed up. He had by this time quite killed the beautifully striped animal, but instead of proceeding to eat it, he got up and roared vigorously, until there was an answer, and in a few minutes a lioness, accompanied by four whelps, came trotting up from the same direction as the zebra, which no doubt she had been to drive towards her husband. They formed a fine picture, as they all stood round the carcass, the whelps tearing it and biting it, but unable to get through the tough skin. Then the lion lay down, and the lioness driving her offspring before her did the same for 5 yards off, upon which he got up, and commencing to eat, had soon finished a hind-leg, retiring a few yards on one side as soon as he had done so. The lioness came up next and tore the carcass to shreds, bolting huge mouthfuls, but not objecting to the whelps eating as much as they could find. There was a good deal of snarling and growling among these young lions, and occasionally a stand-up fight for a minute, but their mother did not take any notice of them, except to give them a smart blow with her paw if they got in her way. . . . There was now little left of the zebra but a few bones, which him-

<sup>1</sup> *The Lion and the Elephant*, 1873, p. 19.

<sup>2</sup> Hon. W. H. Drummond, *The Large Game and Natural History of South and South-East Africa*, 1876, p. 278.

dreds of vultures were circling round waiting to pick, while almost an equal number hopped awkwardly about on the ground within 50 or 60 yards of it, and the whole lion family walked quietly away, the lioness leading, and the lion, often turning his head to see that they were not followed, bringing up the rear.

Though not strictly gregarious, lions appear to be sociable towards their own species, and often are found in small troops, sometimes consisting of a pair of old lions, with their nearly full grown cubs, but occasionally of adults of the same sex; and there seems to be good evidence that several lions will associate together for the purpose of hunting upon a preconceived plan. As might be supposed, their natural ferocity and powerful armature are sometimes turned upon one another; combats, often mortal, occur among male lions under the influence of jealousy; and Andersson relates an instance of a quarrel between a hungry lion and lioness over the carcase of an antelope which they had just killed, and which did not seem sufficient for the appetite of both, ending in the lion not only killing, but even devouring his mate. Old lions, whose teeth have become injured with constant wear, often become "man-eaters," finding their easiest means of obtaining a subsistence in lurking in the neighbourhood of villages, and dashing into the tents at night and carrying off one of the sleeping inmates. Lions differ from most of the smaller *Felide* in never climbing trees; indeed, as mentioned before, they are rarely found in forests.

With regard to the character of the lion, those who have had opportunities of observing it in its native haunts differ greatly. The exaggerated accounts of early writers as to its courage, nobility, and magnanimity have led to a reaction, which causes some modern authors to speak of it in language quite the reverse, and to accuse it of positive cowardice and all kinds of meanness. Livingstone goes so far as to say, "nothing that I ever learned of the lion could lead me to attribute to it either the ferocious or noble character ascribed to it elsewhere," and he adds that its roar is not distinguishable from that of the ostrich. Of course these different estimates depend to a great extent upon the particular standard of the writer, and also upon the circumstance that lions, like other animals, undoubtedly show considerable individual differences in character, and behave differently under varying circumstances. They are certainly not so reckless as to be entirely devoid of the instinct of self-preservation, and if one, perhaps satiated with a good meal the night before, unexpectedly disturbed in the day time, will occasionally retreat when confronted, even by an unarmed man, that is scarcely a reason for ascribing cowardice as one of the characteristics of the species. The latest authority, Selous, while never denying the dauntless courage of the lion when hungry or provoked, and vindicating the awe-inspiring character of the roar of several lions in unison, when heard at close quarters, as the grandest sound in nature, says with regard to its outward aspect:—

"It has always appeared to me that the word 'majestic' is admirably applicable to the lion in its wild state, as when seen by daylight he always has a certain look that entirely does away with the idea of fear. To look majestic a lion should hold his head high. The lion does not. When walking he holds it low, lower than the tip of his back, and it is only when he first becomes aware of the presence of man that he sometimes raises his head and looks a little at the intruder, usually lowering it immediately, and settling away with a growl. When at bay, standing with open mouth, and his head low, holding his head low between his shoulders, and keeping his eyes continuously low growling, twitching his tail the while from side to side, no animal can look more unpleasant than a lion; but there is then nothing majestic or noble in his appearance."

Notwithstanding this evidently truthful description of the animal when seen under what may be called unfavourable circumstances, no one with an eye for beauty can contemplate the form of a fine specimen of a lion, at all

events in a state of repose, even though in the confinement of a menagerie, without being impressed with the feeling that it is a grand and noble-looking animal. (W. H. F.)

**LIPARI ISLANDS.** These islands, which take their name from the largest and most populous member of the group, are situated to the north of the eastern half of Sicily, between 38° 20' and 38° 55' N. lat., and 14° 15' and 15° 15' E. long. The seven principal islands are Lipari, Salina, Vulcano, Stromboli, Panaria, Filicudi, and Alicudi; besides which there are ten islets, some of them mere rocks, the remains of a great central volcano now submerged. The total population of the islands in 1871 was 18,400, and the area is less than 50 square miles. They were known to the ancients as the *Hephestiades* or *Vulcaniæ insulæ*, from their supposed connexion with Vulcan; the *Lipitrenses*, from their mythical king Lipara; and the *Eolie insulæ*, from Æolus, who was said to have married the daughter of Lipara, and to have succeeded to the kingdom. Lipara, the chief island, was colonized in the 6th century B.C. by Chidians and Rhodians, who rapidly spread to the adjacent islands of Hiera and Didyme. The new settlers maintained their independence in spite of the attacks of the Tyrrhenian pirates, but they later became subject successively to the Athenians, Carthaginians, and Romans. In the Middle Ages the Saracens took possession of the islands, but they were expelled by the Normans in the 11th century. Finally Ferdinand the Catholic annexed them to Sicily.

Lipari has an area of about 11 square miles, with a population of 12,000. It is mountainous in character, and consists of tuffs and lavas, and of highly siliceous volcanic products such as quartz-trachyte, pumice, and obsidian. The great central cone, Monte Sant' Angelo (1952 feet), is the ruin of an extinct volcano, as is also Monte Chirica (1978 feet); while Campo Bianco or Monte Pelato (1500 feet) is a mountain of white pumice, breached by an outflow of vitreous lava. Hot springs exist in various parts of the island, the most important being those of San Calogero, mentioned by Diodorus Siculus, and situated about 6 miles from the town. The water, which possesses a temperature of 198° Fahr., contains free carbonic acid and sulphuretted hydrogen, together with carbonates of calcium and magnesium, and chlorides of calcium and sodium. The chief town, which stands on the eastern point of the island, is quite modern, and contains no objects of interest. The cathedral and several other churches are within the precincts of the castle, and they are presided over by a bishop and thirty-two canons. The castle is used as a prison for some four hundred malefactors, sent from various parts of Italy. The island is governed by a delegate, subject to the prefect of Messina. The soil is fertile; and a considerable trade is carried on by a number of merchants who export currants, figs, pumice stone, and malmsy wine. Water is scarce owing to the great porosity of the soil.

Six miles to the south of Lipari is the island of Vulcano, anciently known as *Hiera*, *Vulcania*, and *Therusia*. In early times it was a very active volcano; and it is described by Thucydides, Aristotle, and Callias as being frequently in a state of violent eruption. In the 2d century B.C. the smaller island of Vulcanello was upheaved from the sea. The present crater was probably formed during the eruption of 1786, from which time the volcano remained in a quiescent state till the autumn of 1873, when it commenced to discharge clouds of vapour, showers of sand, and large stones. Blue and green flames were also seen to issue from rifts in the floor of the crater. When visited by the writer in 1879, the volcano had again relapsed into the solfatara stage, and it had recently been purchased by a Scotch firm for £8000, for the purpose of extracting alum, boracic

acid, and sulphur from the numerous products which line the sides and cover the floor of the crater. A number of volcanic minerals have been obtained from Vulcano; the most remarkable perhaps was that lately analysed by Professor Cossa of Turin, which was found to contain seven non-metallic elements and eight metals, among them the rare bodies thallium, caesium, and rubidium. The highest point of Vulcano—a portion of the old crater ring—has an altitude of 1601 feet.

A little more than 20 miles to the north-north-east of Lipari, the cone of Stromboli rises from the sea to a height of 3022 feet. It is of special interest to the vulcanologist from the fact that it is the only example in Europe of a volcano in a state of constant activity, and also because, from an elevated point above the crater (which is at the side of the cone below the summit), it is possible, when the wind blows away from the observer, to sit for hours and watch the operations going on within the crater. Such observations, carried out in 1788 by Spallanzani, made him the father of modern vulcanology, and furnished some of the most important data upon which the science is founded. The mountain is mentioned as early as the 4th century B.C.

Between Stromboli and Lipari there is a group of islets representing portions of the crater ring of a great volcano, the largest of which, Panaria (*Ustica*), is 7 miles in circuit, and contains about 200 inhabitants. It produces wheat, oil, and wine. Salina (*Diadyna*), 3 miles to the north-west of Lipari, has an area of 10 square miles, and consists of two volcanic cones rising respectively to the height of 3156 and 2821 feet. The island contains nearly 5000 inhabitants, who are mainly employed in cultivating the vine, which produce a fine malmsey wine. The cone of Filicudi rises to a height of 2598 feet, some 10 miles to the west of Salina, while at an equal distance further west is Alicudi, the most westerly member of the Lipari group. It is partly cultivated and is inhabited by about 500 fishermen and shepherds.

Good maps of the Lipari Islands have been published by the Italian Government. The best general account of the islands is still that of Admiral Smyth (*Sicily and its Islands*, 1824), while Professor J. W. Judd has exhaustively discussed their geology in the pages of the *Geological Magazine* for 1875. (G. F. R.)

**LIPETSK**, a district town of Russia, in the government of Tamboff, 95 miles west of the chief town of the government, and 23 miles north west of Gryazi railway junction, at the confluence of Lyesnoy Voronesh and Lipovka rivers. The town is built of wood, and the streets are unpaved, but it is a commercial centre of some importance. There are several beetroot-sugar and leather works, tallow-melting houses, and distilleries. There is a brisk business at the weekly fairs, and the merchants carry on active trade in horses, cattle, tallow, skins, and honey, sent by rail to the northern provinces, and in timber, shipped down to the province of the Don Cossacks. The Lipetsk mineral springs came into repute in the time of Peter I., who caused them to be surrounded by galleries, and laid down three gardens; they continue to attract visitors during the summer. Lipetsk received municipal institutions in 1779. Population 14,500.

**LIPPE** is the name of a territory in north-western Germany, now divided into two small sovereign principalities, but formerly united under the same ruler. The name is derived from the river Lippe, which rises in the Teutoburgian Forest, and flows into the Rhine at Wesel.

**I. LIPPE proper**, also called **LIPPE-DETMOLD**, is bounded on three sides by the Prussian province of Westphalia, and on the E. and N.E. by Hanover, Pymont, and Hesso-Cassel. It also possesses three small enclaves in Westphalia. Its area is about 450 square miles. The greater part of the surface is mountainous especially towards the south, where it is intersected by the Teutoburgian Forest. The chief rivers are the Weser, which crosses the north extremity of the principality, and its affluents the Werre, Exter, Kalle, and Emmer. The forests of Lippe are among the finest in Germany, and

produce abundance of excellent timber. The valleys contain a considerable amount of good arable land, the tillage of which occupies the greater part of the inhabitants. The principal crops are corn, flax, and rape. Cattle, sheep, and swine are also reared, and the "Seuner" breed of horses is celebrated. The industries of Lippe are almost confined to a little yarn-spinning and linen-weaving. Its trade is also inconsiderable; but, besides agricultural products, timber, meerschaum pipes, and starch are exported. The brine springs of Salzuffen produce about 1500 tons of salt annually. In 1880 the population amounted to 120,216 souls, upwards of 95 per cent. of whom were Calvinists (Reformed Church), the remainder being Lutherans, Roman Catholics, and Jews. Education is provided for by two gymnasia and numerous other efficient schools. The principality contains seven small towns, the chief of which are Detmold, the seat of government, and Lemgo. The present constitution was granted in 1836, and is modified by a new election law of 1876. It provides for a representative chamber of twenty-one members, whose functions are mainly consultative. For electoral purposes the population is divided into three classes, rated according to taxation, each of which returns seven members. The estimated revenue in 1881 was £49,200, and the expenditure £50,850. The public debt amounts to nearly £60,000. Lippe has one vote in the German Reichstag, and also one vote in the Federal Council. Its military forces form a battalion of the 6th Westphalian infantry.

**II. SCHAUMBURG-LIPPE**, or **LIPPE-BECKBURG**, to the north of Lippe-Detmold, consists of the western half of the old county of Schaumburg, and is surrounded by Westphalia, Hanover, and the Prussian part of Schaumburg. The northern extremity of the principality, which is 175 square miles in extent, is occupied by a lake named the Stemmler Meer. The southern part is mountainous, but the remainder consists of a fertile plain, producing abundant crops of cereals and flax. Besides husbandry, the inhabitants pursue yarn-spinning and linen-weaving, and the coal-mines of the Beckburg, on the southern extremity, are very productive. The great bulk of the population, which in 1880 amounted to 35,374, are Lutherans. The capital is Beckburg, and Stadthagen is the only other town. Under the constitution of 1868 there is a legislative diet of fifteen members, ten of whom are elected by the towns and rural districts and three by the nobility, clergy, and educated classes, while the remaining two are nominated by the prince. Schaumburg-Lippe sends one deputy to the Federal Council, and has one vote in the Reichstag. It contributes a battalion of riflemen to the imperial army. The budget of 1881-82 showed an estimated revenue of £25,750, which was balanced by the expenditure. The public debt is about £18,000.

*History.* The district now named Lippe was included in the earliest times of which we have any record by the Cherusci, whose leader Arminius annihilated the legion of Varus in the Teutoburgian Forest A.D. 9. It was afterwards occupied by the Saxons, and was subdued by Charlemagne. The founder of the present reigning family, one of the most ancient in Germany, was Bernard I. (1128-58), who received a grant of the territory, till then called the county of Halber, from the emperor Lothar, and assumed the title of lord of Lippe. Bernard VIII., who with his people embraced the tenets of the Reformation in 1556, was the first to style himself count of Lippe. In 1613 Lippe was divided among the three sons of Simon VI., the line founded by two of whom still exist, while the third (Halle) became extinct in 1769.

Lippe-Detmold was the patrimony of the eldest son, whose descendants became princes of the empire in 1789. In 1809 it joined the Confederation of the Rhine, and in 1814 the German Confederation. Under the prudent government of the Princess Pauline (1807-20) the little country enjoyed great prosperity. Her son, Paul Alexander Leopold, ruled in the same spirit, and in 1836 granted the charter of rights on which the government is now based. In 1842 Lippe entered the German Customs Union

(Zollverein), and in 1866 it threw in its lot with Prussia and joined the North German Confederation.

Philip, the youngest son of Simon VI. (see above), received but a scanty share of his father's possessions, but in 1640 he inherited a large part of the countship of Schaumburg, including Bückeburg, and adopted the title of count of Schaumburg-Lippe. The ruler of this territory became a sovereign prince in 1807. In 1866 the prince at last sided with Austria, but afterwards entered the German Confederation.

For further information consult Falkmann, *Beiträge zur Geschichte des Fürstentums Lippe*, 1807; Schöckert, *Das Fürstentum Lippe-Detmold in Vergangenheit, Gegenwart und künftiger Beziehung*, 1897; Lünning, *Die Lippe und die Lippen in der Geschichte*, in *Siebolds Historische Zeitschrift*, 1861.

LIPPI, the name of three celebrated Italian painters.

I. FRA FILIPPO LIPPI (1412-1469), commonly called Lippo Lippi, one of the most celebrated painters of the Italian quattrocento, was born in Florence,—his father, Tommaso, being a butcher. His mother died in his earliest infancy, and his father two years later. His aunt, a poor woman named Monna Lapaccia, then took charge of him; and in 1429, when only eight years of age, he was registered in the community of the Carmelite friars of the Carmine in Florence. Here he remained till 1432, and his early faculty for fine art was probably developed by studying from the works of Masaccio in the neighbouring chapel of the Brancacci. Between 1430 and 1432 he executed some works in the monastery, which were destroyed by a fire in 1771; they are specified by Vasari, and one of them was particularly marked by its resemblance to Masaccio's style. Eventually Fra Filippo quitted his convent, but it appears that he was not relieved from some sort of religious vow; there is a letter of his, dated in 1439, in which he speaks of himself as the poorest friar of Florence, and says he is charged with the maintenance of six marriageable nuns. In 1452 he was appointed chaplain to the convent of S. Giovanni in Florence, and in 1457 rector (*Rettore* *Univ. di S. Maria*) of S. Quirico at Legnaia, and his gains were considerable, and even uncommonly large from time to time; but his poverty seems to have been chronic none the less, the money being spent, according to one account, in frequently recurring amours.

Vasari relates some curious and romantic adventures of Fra Filippo, which modern biographers are not inclined to believe. Except through Vasari, nothing whatever is known of his visits to Ancona and Naples, and his intermediate capture by Barbary pirates and enslavement in Barbary, whence his skill in portrait-sketching availed to release him. The double-throw upon his sentimental relations with a Florentine lady appear, however, to be some what accurate; Vasari's account is circumstantial, and merits more credit, especially as to say that he is the sole author, for the facts goes but a small way towards invalidating them. Towards June 1456 Fra Filippo was settled in Prato (near Florence) for the purpose of fulfilling an important commission which had been given him to paint frescos in the choir of the cathedral. But in actually undertaking this work he set about painting, in 1457, a picture for the convent chapel of St. Martin at Prato, and there saw Lucrezia Buti, the beautiful daughter of a Florentine, Francesco Buti; she was either a novice, or a young lady placed under the nuns' guardianship. Lippi asked that the night be permitted to sit to her for the form of the Madonna; he made passes to her, seduced her to his own house, and kept her there, spite of the utmost efforts the nuns could make to recover her. The fruit of their loves was a boy, who became the painter, not less celebrated than his father, Filippino Lippi (next of below). Such is substantially Vasari's narrative, published less than a century after the alluded events; it is contradicted by rhyme, more than three centuries later, that prince Lippo had nothing to do with any such Lucrezia, and perhaps Lippino was his adopted son, or only an ordinary relative and scholar. The argument that two reputed portraits of Lucrezia in

paintings by Lippo, one as a Madonna in a very fine picture in the Pitti gallery, and the other in the same character in a Nativity in the Louvre, are not alike comes to very little; and it is reduced to nothing when the disputant adds that the Louvre painting is probably not done by Lippi at all. This painting comes, however, from St. Margaret's at Prato, and is generally considered to be the very one on which Vasari's story hinges.

The frescos in the choir of Prato cathedral, being the stories of the Baptist and of St. Stephen, represented on the two opposite wall spaces, are the most important and monumental works which Fra Filippo has left, more especially the last of the series, showing the ceremonial mourning over Stephen's corpse. This contains a portrait of the painter, but which is the proper figure is a question that has raised some diversity of opinion. Some of the subjects are legendary, as, for instance, the attempt of the devil to substitute a changeling for the infant protomartyr. At the end wall of the choir are S. Giovanni Gualberto and S. Albert, and on the ceiling the four evangelists.

The close of Lippi's life was spent at Spoleto, where he had been commissioned to paint, for the apse of the cathedral, some scenes from the life of the Virgin. In the semidome of the apse is Christ crowning the Madonna, with angels, sibyls, and prophets. This series, which is not wholly equal to the one at Prato, was completed by Fra Diamante after Lippi's death.

That Lippi died in Spoleto, on or about 8th October 1469, is an undoubted fact; the mode of his death is again a matter of dispute. It has been said that the pope granted Lippi a dispensation for marrying Lucrezia, but that, before the permission arrived, he had been poisoned by the indignant relatives either of Lucrezia herself, or of some lady who had replaced her in the inconstant painter's affections. This is now generally regarded as a fable; and it may very well be such, although the incident does not present any intrinsic improbability in relation to the Italy of the 15th century. Fra Filippo lies buried in Spoleto, with a monument erected to him by Lorenzo the Magnificent; he had always been zealously patronized by the Medici family, beginning with Cosmo Pater Patriæ. Fra Sebastiano Pesello (called Pesellino) and Sandro Botticelli were among his most distinguished pupils.

Lacking pictures by Lippi not already mentioned are the 2. In 1441 he painted an altarpiece for the nuns of S. to which is now a prominent attraction in the Accademia of Florence, and has been celebrated in Browning's well-known poem. It is the Coronation of the Virgin among angels and saints, and many are Bernardine monks. One of these, placed to the right, is a half-length portrait of Lippo, pointed out by an inscription on an angel's scroll "Is perfect opus." The price paid for it in 1447 was 1200 Florentine lire, which seems surprisingly countably large. For Geminiano Inghirami of Prato dated the death of St. Bernard, a fine specimen still extant. In the altarpiece in this city is a Nativity in the refectory of the convent of S. Donato, the Infant on the ground adored by the Virgin and angels, between Sts. George and Dominic, in a rocky landscape, with the shepherds playing and six angels in the sky. In the Prato is a fine Virgin adoring the infant Christ, who is held by two angels; in the London National Gallery, a Vision of St. Bernard. The picture of the Virgin and Infant with an Angel, in this same gallery, also ascribed to Lippi, is disputable.

Few pictures are so thoroughly enjoyable as those of Lippo Lippi; they show the naïveté of a strong rich nature, redundant in lively and somewhat whimsical observation. He approaches religious art from a human side and is not pictorial though true to a phase of Catholic devotion. He was perhaps the greatest colourist and technical adept of his time, with good draughtsmanship,—a naturalist, with less vulgar realism than some of his contemporaries, and with much genuine episodic animation, including semi-humorous incidents and low characters. He made little effort after perspective and none for foreshortenings, was fond of ornamenting pilasters and other architectural features. Vasari says that Lippi was wont to hide the extremities in drapery, to evade difficulties. His career was one of continual development, without fundamental variation in style or in colouring. In his great works the proportions are larger than life.

**II. FILIPPINO or LIPPINO LIPPI (1460–1505)** was the natural son of Fra Lippo Lippi and Lucrezia Buti, born in Florence and educated at Prato. Losing his father before he had completed his tenth year, the boy took up his avocation as a painter, studying under Sandro Botticelli, and probably under Fra Diamante. The style which he formed was to a great extent original, but it bears clear traces of the manner both of Lippo and of Botticelli,—more ornamental than the first, more realistic and less poetical than the second. His powers developed early; for we find him an accomplished artist by 1480, when he painted an altarpiece, the Vision of St Bernard, now in the Badia of Florence; it is in tempera, with almost the same force as oil painting. Soon afterwards, probably from 1482 to 1490, he began to work upon the frescoes which completed the decoration of the famous Brancacci chapel in the Carmine, commenced by Masolino and Masaccio many years before. He finished Masaccio's subject of the Resurrection of the King's Son, and was the sole author of Paul's Interview with Peter in Prison, the Liberation of Peter, the Two Saints before the Proconsul, and the Crucifixion of Peter. These works, were none others extant from his hand, are sufficient to prove that Lippino stood in the front rank of the artists of his time. The dignified and expressive figure of St Paul in the second-named subject has always been particularly admired, and appears to have furnished a suggestion to Raphael for his Paul at Athens. Portraits of Luigi Pulci, Antonio Pollaiuolo, Lippino himself, and various others are to be found in this series. In 1485 he executed the great altarpiece of the Virgin and Saints, with several other figures, now in the Uffizi Gallery. Another of his leading works is the altarpiece for the Nerli Chapel in S. Spirito—the Virgin Enthroned, with splendidly living portraits of Nerli and his wife, and a thronged distance. In 1489 Lippino was in Rome, painting in the church of the Minerva, having first passed through Spoleto to design the monument for his father in the cathedral of that city. Some of his principal frescos in the Minerva are still extant, the subjects being in celebration of St Thomas Aquinas. In one picture the saint is miraculously commended by a crucifix; in another, triumphing over heretics. In 1496 Lippino painted the Adoration of the Magi now in the Uffizi, a very striking picture, with numerous figures. This was succeeded by his last important undertaking, the frescos in the Strozzi Chapel, in the church of S. Maria Novella in Florence—Drusiana Restored to Life by St John the Evangelist, St John in the Cauldron of Boiling Oil, and two subjects from the legend of St Philip. These are conspicuous and attractive works, yet somewhat grotesque and exaggerated, full of ornate architecture, showy colour, and the distinctive peculiarities of the master. Filippino, who had married in 1497, died in 1505 of an attack of throat disease and fever, aged only forty-five. His character for amiability and courtesy is described in very laudatory terms by Vasari. The best-reputed of his scholars was Raffaellino del Garbo.

Like his father, Filippino had a most marked original genius for painting, and he was hardly less a chief among the artists of his time than Fra Filippo had been in his; it may be said that in all the annals of the art a rival instance is not to be found of a father and son each of whom had such pre-eminent natural gifts and leadership. The father displayed more of sentiment, and candid sweetness of motive; the son more of richness, variety, and lively pictorial combination. He was admirable in all matters of decorative adjunct and presentment, such as draperies, landscape backgrounds, and accessories; and he was the first Florentine to introduce a taste for antique details of costume, &c. He formed a large collection of objects of this kind, and left his designs of them to his son. In his later works there is a tendency to a mannered development of the extremities, and generally to facile overdoing. The London National Gallery possesses a good and characteristic though not exactly a first-rate specimen of Lippino, the Virgin and Child between Sts Jerome and Dominic.

**III. LORENZO LIPPI (1606–1664)**, a painter and poet, was born in Florence. He studied painting under Matteo Rosselli, the influence of whose style, and more especially of that of Santi di Tito, is to be traced in Lippi's works, which are marked by taste, delicacy, and a strong turn for portrait-like naturalism. His maxim was "to poetize as he spoke, and to paint as he saw." After exercising his art for some time in Florence, and having married at the age of forty the daughter of a rich sculptor named Susini, Lippi went as court painter to Linsbuck, where he has left many excellent portraits. There he wrote his humorous poem named *Milareddo Perpetuato*, which was published under the anagrammatic pseudonym of "Perlone Zipoli." Lippi was a friend of Salvator Rosa, and was a man of pleasant and generous temper, and very polite. He was, however, somewhat self-sufficient, and, when visiting Parma, would not look at the famous Correggios there, saying that they could teach him nothing. He died of pleurisy in 1664.

The most esteemed works of Lippi in the gallery at Florence, and the executed for the season of Advent, portraits of the six children of the *Milareddo Perpetuato*, and a number out of a variety of popular devotion. An expedition for the recovery of a buried had been expected by a friend of Lippi, a very Florentine painter, and is recorded by Lippi. Lippi's most popular work, a scene, painted by the poet himself, and a scene of painting. It was not published until his death.

**LIPSIUS, JESSE (1547–1606)**, a Dutch form of Joest Lips, an eminent humanist of the 16th century, born 18th October 1547, at Overyssehe, a small village in Brabant, about half way between Prætor and Ottemes. Sent early to the Jesuit college in Cologne. Removed at seventeen to the university of Leuven. His parents, who had some reason for fearing that he would be induced to become a professed member of the Society of Jesus. But he had received at Cologne two mental gifts from which he never emancipated himself. One of these, which was suppressed or suspended in him, was that of self later in his return to the bosom of the Catholic Church before his death. The other, derived from his Jesuit training, showed itself in his nearly rhetorical or vital view of classical literature, of which the one interest lay in its style.

Lipsius rushed into print at twenty with one of those volumes of miscellaneous remarks then in vogue (*Variorum Lectorum Libri Tres*, 1567), the dedication of which to Cardinal Granvelle procured him an appointment as Latin secretary, and a visit to Rome in the retinue of the cardinal. Here Lipsius remained two years, using his spare time in study of the Latin classics, in viewing the monuments, collecting inscriptions, and handling MS. in the Vatican. A comparison of a second volume of miscellaneous criticism (*Antiquarum Lectorum Libri Quatuor*, 1575), published after his return from Rome, with the *Variorum Lectorum* of eight years earlier shows that he had advanced from the notion of purely conjectural emendation to that of crumbing by collation, and that he had learnt to distinguish between a "good" and a "bad" MS. In Rome he also made the acquaintance of Marcus Paulus Manutius, and the other humanists of the catholic reaction who were then in credit there. He was also noticed by Cardinal Sirleto and Fulvio Orsini; but he can hardly have even seen in the street Sigonio and Vettori, and the introduction of these celebrated names is perhaps only a stylistic flourish of the biographer Le Mire, to whom we owe the only original account of Lipsius's life. In 1570 he wandered over Burgundy, Germany, Austria, Bohemia, in search of learn-

ing and learned acquaintance, and was engaged for more than a year as teacher in the university of Jena, a position which implied an outward conformity to the Lutheran Church. On his way back to Louvain, he stopped some time at Cologne, where he must again have comported himself as a Catholic. Here he married, but the union was without issue, and in other respects did not conduce to happiness, as we gather from various allusions scattered through Lipsius's letters. He returned to Louvain, but was soon driven by the civil war to take refuge in Antwerp, where he received, in 1579, a call to the newly founded university of Leyden, as professor of history.

At Leyden, where he must have outwardly conformed to the Calvinistic creed and worship, Lipsius remained eleven years,—years about which his Catholic biographer Le Mire has nothing to tell, but speaks of the period as an enforced temporary sojourn among the infidels,—till the restoration of peace allowed him to return to his home in Brabant. In truth, this period of Lipsius's life was the period of his greatest productivity. It was now that he prepared his *Seneca*, and that he perfected, in successive editions, his *Tacitus*. To edit and comment on two authors of the first class, such as Tacitus and Seneca, in addition to the daily drudgery of teaching, might seem work enough for eleven years. But Lipsius's industry enabled him, over and above, to bring out, from the press of Plantin at Antwerp, a series of works of varied character and contents, some of pure scholarship, others collections from classical authors, and others again of more general interest. Of this latter class was a treatise on politics (*Politicon Libri Sex*, 1589), in which he let it be seen that, though a public teacher in a country which professed toleration, he had not departed from the state maxims of Alva and Philip II. He lays it down that a Government should only suffer one religion to exist in its territory, and that dissent should be extirpated by fire and sword. This frank avowal of what were known to be his real sentiments might have easily had disagreeable consequences for the author, if he had not been sheltered from the attacks to which it exposed him by the prudence of the authorities of Leyden. Lipsius was prevailed upon to publish a declaration that his expression "*Ure, sed*," was not intended of material fire and sword, but was only a metaphor for "vigorous treatment."

The time at last arrived when Lipsius, who had always been somewhat ill at ease in his Calvinistic disguise, was to throw it off and return into the bosom of the church. In the spring of 1591 he left Leyden under pretext of taking the waters at Spa for the relief of a liver complaint. He went to Mainz, where he was reconciled to the church by the instrumentality of the Jesuit fathers. The event was one which deeply interested the Catholic world, and invitations poured in on Lipsius from the courts and universities of Italy, Austria, and Spain. But he preferred to remain in his own country, and after two years of unsettled residence at Liège, Spa, &c., settled at Louvain, as professor of Latin in the Collegium Basilianum. He was not expected to teach, and his trifling stipend was eked out by the appointment of privy councillor and historiographer to the king of Spain.

From this time till his death Lipsius continued to publish antiquarian collection and dissertation as before. But he was, in fact, but to be ending. His name and fame, and his sententious and manly style, were placed at the disposal of the devotees, and used by them to restore the credit of two local images of the Virgin, whose authentic miracles were retailed by Lipsius in two tracts, *Dea Virgo Halensis*, and *Dea Virgo Sichemensis*. Joseph Hall, afterwards bishop of Norwich, was at Spa in the suite of Sir E. Bacon at the time of the appearance of Lipsius's brochures, and was like to have got into trouble by disput-

ing against them (Hall's *Epistles*, cent. i. ep. 5). Lipsius died at Louvain on the 23d of March 1606, at the age of fifty-eight. His Greek books and MSS. he left to the Jesuit college at Louvain; the rest of his library, choice rather than extensive, to a nephew. His furred doctor's robe he ordered to be offered at the shrine of the Virgin at Hall.

If, according to the fancy of some biographers, Scaliger, Casaubon, and Lipsius be erected into a literary triumvirate, Lipsius represents Lepidus. His knowledge of classical antiquity was extremely limited. He had but slight acquaintance with Greek; "pour sa provision" only, said Scaliger. He is fond of adorning his letters with Greek phrases, his quotations betraying that he is a stranger in that country. In Latin literature the poets and Cicero lay outside his range; he had no ear for metre, and no taste for poetical expression. Where he was strong was in the Latin historians and in Roman antiquities. His greatest work was his edition of Tacitus. This author he had so completely made his own that he could repeat the whole, and offered to be tested in any part of the text, with a poniard held to his breast, to be used against him if he should fail. His *Tacitus* first appeared in 1575, and was five times revised and corrected by the editor—the last time in 1606, shortly before his death. His *Seneca* is dated Antwerp, 1605. His *Opera Omnia* were collected in 4 vols., Antwerp, 1637, of which the Wesel edition, 1675, is a verbal reprint in the same number of volumes, but in a smaller form. The first volume contains also Le Mire's *Life of Lipsius*, which had appeared separately in 1607. Both editions contain ten centuries of his epistles, to which additions have been made in *Epistolæ quæ in Centuriis non ex ant. Decades XII.*, &c., Harderwijk, 1621; Burmann's *Sylloge*, tom. i.; *Lettres inédites*, cl. Delprat, Amst., 1858. On Lipsius's relations with Scaliger see Bernay's *J. J. Scaliger*, note 40. A bibliographical list of his separate publications, forty-eight in number, may be found in Nie ron, *Mémoires*, xxiv. p. 118. (M. P.)

LIQUEURS are perfumed and sweetened spirits prepared for drinking, and for use as a flavouring material in confectionery and cookery. The term liqueur is also applied to certain wines and spirits remarkable for their amount of bouquet, such as tokay and liqueur brandy, &c. Ordinary liqueurs consist of certain mixtures of pure spirit with essential oils and vegetable extracts, and with syrup of refined sugar. A certain number of such preparations have an established reputation; but the methods by which these are compounded, and the precise proportions of the various ingredients they contain, are valuable trade secrets, scrupulously kept from public knowledge.

The raw materials employed in the preparation of liqueurs are (1) a pure flavourless spirit, which must be free from fusel oil; (2) various essential oils, on the purity and constant quality of which much of the success of the manufacture depends, or, in place of the oils, the aromatic substances from which they may be distilled; (3) bitter aromatic vegetable substances, fruits, rinds, &c., or their alcoholic extracts called tinctures; (4) fresh juicy fruits possessed of special flavour; (5) refined sugar prepared in the form of a perfectly smooth colourless syrup; (6) soft or distilled water; and (7) tinctorial substances for those liqueurs in which a particular colour is demanded by fashion. The French, who excel in the preparation of liqueurs, grade their products according to their sweetness and alcoholic strength into *crèmes*, *huiles*, or *baumes*, which have a thick oily consistency, and *eaux*, *extraits*, or *elixirs*, which, being less sweetened, are perfectly limpid. Liqueurs of British fabrication, generally of inferior quality, are frequently dealt in under the name of *cordials*. Bitters form a class of liqueurs by themselves, claiming to possess certain tonic properties and a medicinal value. Certain liqueurs, containing only a single flavouring ingredient, or having a prevailing flavour of a particular substance, are named after that body, as for example—*crème de rose*, *vanille*, *thé*, *cacao*, *anisette*, and *kümmel*, &c. On the other hand, the liqueurs which in general are most highly prized are compounded of very numerous aromatic principles, and they are not considered fit for use till they have matured and mellowed for several years.

The simplest method of preparing liqueurs is by adding the requisite proportion of essential oil to spirit of known strength, and then mixing this with the necessary amount of clear syrup. In this way, indeed, the greater number of the commoner and cheaper kinds are manufactured. Thus for making (say) 20 gallons inferior quality of kummel, there are added to 7 gallons of spirit of wine  $\frac{1}{4}$  lb of essential oil of caraway seed,  $7\frac{1}{2}$  drachms of fennel-seed oil, and 15 drops of bitter almond oil. With this preparation is mixed a syrup containing 40 lb of refined sugar dissolved in about 12 gallons of water, and when fined with gelatine or with alum and soda solution the liqueur is ready for use. To prepare, on the other hand, 20 gallons of fine kummel liqueur, there would be placed in a simple still, with 10 gallons of spirit and 8 of water, 4 lb of caraway seeds,  $\frac{1}{4}$  lb of fennel, and 2 oz. of Florentine iris root. This mixture after maceration is distilled, the first portion of the distillate being put aside on account of its rough aroma, after which about 8 gallons of fine kummel spirit is obtainable. There still may be procured, by forcing the heat, from 3 to 4 gallons of inferior spirit. To the 8 gallons of fine spirit is added a syrup consisting of 60 lb of refined sugar dissolved in 10 gallons of water, the two compounds being thoroughly incorporated with heat in an open vessel. On cooling, the amount of water necessary to make up 20 gallons is added; the liqueur is fined with isinglass, and stored to mature and mellow. All varieties of liqueurs may be made or imitated by both these methods; but as a rule it is only the simple-flavoured and commoner varieties which are compounded by the addition of essential oils and alcoholic tinctures. Fine liqueurs are made by macerating aromatic bodies and subsequent distillation; bitters by maceration and straining.

Of trade liqueurs the most highly esteemed in the United Kingdom are Chartreuse, Curaçoa, Maraschino, and Doppel-Kummel or Allasch. Of all kinds the most famous is Chartreuse, so called from being made at the famous Carthusian monastery near Grenoble. Three qualities are made—green, yellow, and white, the green being the richest and most delicate in flavour. Chartreuse is said to be a most complex product, resulting from the maceration and distillation of balm leaves and tops as a principal ingredient, with orange peel, dried hyssop tops, peppermint, wormwood, angelica seed and root, cinnamon, mace, cloves, Tonquin beans, *Calamus aromaticus*, and cardamoms. Curaçoa, which is a simple liqueur, is chiefly made in Amsterdam from the dried peel of the Curaçoa orange. The peel is first softened by maceration in water; then three-fourths of the quantity in preparation is distilled with mixed spirit and water, and the remaining fourth is macerated in a proportion of this distillate for two or three days; the tincture is strained off and expressed and added to the original distilled Curaçoa spirit. The flavour of Curaçoa is improved by the addition of about one per cent. of Jamaica rum. The centre of the Maraschino trade is at Zara in Dalmatia. Genuine Maraschino is prepared from a variety of cherry—the Marasca—peculiar to the Dalmatian mountain regions. The juice of the cherry fermented and distilled yields the spirit, which is flavoured with the broken cherry kernels themselves. Imitations of Maraschino are easily prepared, a praiseworthy liqueur resulting from raspberry juice, bitter almonds, and orange-flower water. In the preparation of Allasch which is a rich Kummel bitter almonds, star-anise, angelica root, Florentine iris root, and orange peel are used in addition to caraway seeds. Gold-water and silver-water are liqueurs to which small quantities of powdered gold-leaf and silver-leaf have been added, on account of their lustre. They are now little used.

Gentian root is the fundamental "bitter" in most of the preparations known as Bitters. These compounds, prepared by maceration, are very various in their constitution, but the following is a fair typical sample of the composition of a kind largely used. To prepare 20 gallons of bitters there are taken 6 lb of gentian, 5 lb each of cinnamon and caraway seeds, 1 lb of juniper berries, and  $\frac{1}{2}$  lb of cloves. These are macerated in 7 gallons of spirit, 60° over proof, strained and filtered, and to the product is added 10 lb of sugar dissolved in 13 gallons of water, and the resulting liquor is coloured with cochineal.

The following list includes the names of the principal commercial liqueurs not already named:—Noyeau (white and pink), trappistine (yellow and green) (from the Abbey de la Grâce Dieu), bénédictine (from Fécamp), peppermint liqueur, French cherry brandy or kirschbaer (from Copenhagen), mandarine, parfait amour, crème de

vanille, crème de rose, thé, café, menthe, cacao, vanille, pomegranzen, ratafia (from Dantzic), anisette (from Amsterdam and Bonaux), kirschenwasser (from Switzerland and the Black Forest), absinthe, and vermouth. (J. P.A.)

**LIQUIDAMBAR, LIQUID AMBER, or SWEET GUM**, is a product of *Liquidambar styraciflua*, L., order *Hamamelidaceæ*, a deciduous tree of from 30 to 50 feet high and attaining 15 feet in circumference in Mexico, of which country it is a native, as well as of the greater portion of the United States. It bears palmately lobed leaves, somewhat resembling those of the maple, but larger. The male and female inflorescences are on different branches of the same tree, the globular heads of fruit resembling those of the plane. This species is nearly allied to *L. orientalis*, Miller, a native of a very restricted portion of the south west coast of Asia Minor, where it forms forests. It is from the bark of this latter tree that the storax of the ancients (Herod., iii. 107; Diosc., i. 79), the medicinal styrax of today, is prepared (Bentley and Tunon, *Med. Plants*, No. 107). The earliest record of the tree appears to be in a Spanish work by F. Hernandez, published in 1651, in which he describes it as a large tree producing a fragrant gum resembling liquid amber, whence the name (*Nov. Plant.*, &c., p. 56). In Ray's *Hist. Plantarum* (1686) it is called *Styrax liquida*. It was introduced into Europe in 1681 by Banister, the missionary collector sent out by Bishop Compton, who planted it in the palace gardens at Fulham.

The wood is very compact and fine-grained, the heart-wood being reddish, and, when cut into planks, marked transversely with blackish belts. It is employed for veneering in New York. Being readily dyed black, it is sometimes used instead of ebony for picture frames, balusters, &c.; but it is too liable to decay for out door work. The principal product of the tree, however, is the resinous gum which issues from between the bark and wood. It is sometimes called white balsam of Peru, or liquid storax, though it is said by Michaux (*Les Végét. résineux*, ii. p. 337) to differ materially from the latter. It is considered to be styptic and to possess heating and balsamic properties, being stimulant and aromatic. It possesses nearly the same properties as the balsam of Peru and of Tolu, for which it is often substituted, as well as for storax. Mixed with tobacco, the gum was used for smoking at the court of the Mexican emperors (Humb., iv. 10). It has been long used in France as a perfume for gloves, &c. It is mainly produced in Mexico, little being obtained from trees growing in higher latitudes of North America, or in England. For localities where it has been observed, see Pickering's *Chem. Hist. of Plants*, p. 741.

**LIQUORICE.** The hard and semi-vitreous sticks of paste, black in colour and possessed of a sweet somewhat astringent taste, known as liquorice paste or black sugar, are the inspissated juice of the roots of a leguminous plant, *Glycyrrhiza glabra*, the *radix glycyrrhizæ* of the pharmacopœia. The plant is cultivated throughout the warmer parts of Europe, especially on the Mediterranean shores, and its geographical limits travel eastward throughout Central Asia to China, where its cultivation is also prosecuted. In the United Kingdom it is grown in Surrey and in York-shire. The roots for use are obtained in lengths of 3 or 4 feet, and varying in diameter from  $\frac{1}{4}$  to 1 inch, soft, flexible, and fibrous, and internally of a bright yellow colour with a characteristic sweet pleasant taste. To this sweet taste of its root the plant owes its generic name *Glycyrrhiza* (the sweet root), of which liquorice is a corruption. According to the analysis of Sestini (*Gaz. Chim. Ital.*, vol. vii. p. 31), the root dried at 110° C. has the following composition:—resin, fat, and colouring matters, 3.220; glycyrrhizin, 6.378; starch, 57.720; cellulose, 19.790; albuminoid substances,

6.373; ammonia (combined), 0.043; asparagine, 2.416; ash, 4.060. It is to the sugar-like body glycyrrhizin in combination with ammonia that the peculiar taste and properties of liquorice root are due. Glycyrrhizin in itself is a tasteless nearly insoluble substance having the composition of  $C_{42}H_{64}O_{16}$ ; but in combination with ammonia, potash, or soda it develops its sweet taste. It is easily precipitated from its combination by the influence of mineral acids. Liquorice has been known and its virtues appreciated from the most remote periods, and the root is an article of some commercial importance on the Continent.

Stick liquorice is made by crushing and grinding the roots to a pulp, which is boiled in water over an open fire, and the dextrin separated from the solid residue of the root is evaporated in copper pans till a sufficient degree of concentration is attained, after which, on cooling, it is rolled into the form of sticks or other shapes for the market. The preparation of the juice is a widely extended industry along the Mediterranean coasts; but the quality best appreciated in the United Kingdom is made in Calabria, and sold under the names of Solima and Corigliano juice. The liquorice grown in Yorkshire is made into a confection called Pontifical cakes. Liquorice in various forms is a popular remedy for coughs, and it is largely used by children as a sweetmeat. It enters into the composition of many cough lozenges and other demulcent preparations; and in the form of aromatic syrups and elixirs it has a remarkable effect in masking the taste of nauseous medicines, a property peculiar to glycyrrhizin. A considerable quantity of liquorice is used in the preparation of tobacco for chewing. Commercial liquorice paste is frequently much adulterated, and often contains distinct traces of copper, apparently derived from the vessels in which the juice is inspissated.

LIQUOR LAWS may be divided into the three great systems of free trade, restriction, and prohibition. The system of free trade may mean either that no special licence is required by law for carrying on a traffic in intoxicating liquors, or that such a licence is required, but that the licensing authority is bound to grant it in every case in which certain conditions are complied with. Wherever the determination of these conditions involves an appeal to the discretion of the licensing authority, the system of free trade tends to pass into the system of restriction. For practical purposes it does not matter much whether the law says, "every man of good character is entitled to a licence for a properly constructed house in a suitable locality," or "the magistrate must consider the character of the applicant and of the premises, but is not bound to give reasons for his decision." But wherever the applicant can submit to a court capable of dealing with evidence the question of fact whether he has fulfilled certain conditions defined by law, the system of free trade may be said in theory to exist. Wherever, on the other hand, the law distinctly affirms an absolute discretion in the magistrate, or lays down a positive principle, such as the "normal number" or the fixed proportion between public-houses and population, the system is properly described as restriction, or monopoly. This system, again, in its extreme form, tends to pass into one of prohibition. Under one of the alternative plans permitted by the Swedish licensing law of 1855, generally known as the Gothenburg plan, the municipality begins by the partial, and advances to the total, prohibition of liquor traffic, except by servants of the municipality; and this plan is sometimes advocated merely as a step towards the suppression of all trade in liquor. In nearly all countries the nature of the trade carried on in public houses has subjected them to a much more rigorous police supervision than ordinary trades. All trades, however, must be carried on under the conditions required by the public comfort and safety; and to give unlimited licence in such matters to publicans would be to violate social rights not inferior to freedom of industry and trade.

Of recent years there has been a considerable increase in the amount of drunkenness in Europe generally. There

are no means of determining the law of the increase by reliable statistics, but it seems probable that the increase is confined to the large towns and to the lowest classes. There has also been of late, both in the United Kingdom and on the Continent, a very earnest and animated discussion on the policy and results of the various systems of liquor law. It cannot be said that so far any decisive experience has been adduced on the subject. In fact the legislation of Europe is in a very uneasy and changeful state. Thus, prior to the federal constitution of 1874, the cantons of Switzerland were in the habit of directing the municipal authorities to observe a certain proportion between the number of licences and the population. The new constitution, however, laid down the general principle of free trade, and the federal council intimated to the various cantons that it was no longer lawful to refuse a licence on the ground that there was no public need of it. In the previous year precisely the opposite change took place in Denmark. The licence system rested on the law of 29th December 1857, but this was modified by the law of 23d May 1873, which increased the conditions to be fulfilled by those applying for a licence, and conferred upon the communal authorities the power of fixing the maximum number of licences to be granted. Similarly, in France, the liquor law rests upon the decree of 1851, but public opinion is turning against the absolute discretion reposed in the administrative authority, and the law proposed by M. de Gasté and approved of by the chamber of deputies on 22d March 1878 will probably lead to a system of greater freedom. In the German empire the various states are still permitted by a law of the confederation, dated 21st June 1869, to restrict the issue of licences to what the public seem to require, but except in Württemberg this permission seems not to have been used. In Austria the rapid growth of drunkenness in Galicia made necessary the severe police law of 19th July 1877, but in other parts of the empire the exceptionally lenient law of 20th December 1859 seems to be considered sufficient. In the midst of so many fluctuations of opinion, the practical questions of legislation must be decided on general principles and not by experimental evidence. Those who speak and write on the reform of the liquor laws are divided into two great classes—(1) the nephelists, who consider alcohol, in every form, whether in distilled or in fermented liquors, to be poison, and therefore wish the sale of it to be entirely suppressed; (2) those who see no objection to moderate drinking especially of the less alcoholic beverages, or at least regard the idea of suppression as an impracticable chimæra. In the United Kingdom the nephelists are at present agitating for Sir Wilfrid Lawson's Permissive Bill, which has latterly taken the form of a local option resolution. This means that in each burgh or parish two-thirds of the ratepayers may decide that no licences shall be given, a vote to be taken on the subject every three years. On 17th March 1879 the select committee of the House of Lords on intemperance reported emphatically against the scheme of the Permissive Bill. The committee did not examine witnesses from the United States with respect to the experiments in prohibition which have been made there on a large scale; but it is generally admitted that the Maine Liquor Law has succeeded only in villages and rural districts; in towns it has failed. So also the Michigan Law, prohibiting the sale of liquor except for medicinal or mechanical purposes, was condemned after twenty years' experience; and in 1875 a licence tax was imposed on dealers in liquor.

The result is the same under those celebrated "local option laws" which are in force in some of the United States. These laws proceed from the legislatures of the various States. They sometimes take the form of a general prohibition of the sale of intoxicants,

subject to a vote of the inhabitants in each township or county, but more frequently they merely provide in general terms for the issue of licences in the usual way, unless the local constituency shall otherwise determine. Such laws are in force in Massachusetts, New Jersey (which had the Chatham Local Option Law of 1871), New Hampshire, Connecticut, and Vermont. But whether they are constitutional or not is a matter of serious controversy in the courts of the United States. On the one hand, it is said that such a law amounts to a delegation by the State of its legislative power, —that it leaves the hands of the senate and general assembly in an unfinished state, commanding nothing, prohibiting nothing. On the other hand, it is said this is a police regulation, which is properly entrusted to county commissioners, or boards of select men for the protection of the health and morals of the localities over which they preside; and it is quite competent for a State to make a law delegating the power to determine some fact or state of things, upon which the law makes, or intends to make, its own action depend. In the case of the States already mentioned the constitutional character of the local option law has been upheld by decision, but in the cases of Delaware, Texas, Indiana, California (Wall's Case), Iowa, and Pennsylvania, it has been denied. The question has also been raised in the American courts whether in the case of intoxicants being imported from one State to another a local option law, which prohibits the sale of the imported goods, does not violate the freedom of commerce which is guaranteed to all the States by the American Constitution.<sup>1</sup>

Among those who are not nephelists a variety of schemes has been suggested. A small minority are in favour of free trade subject to certain conditions. An experiment of this kind was tried by the Liverpool magistrates in 1853. "The promises were to be of high rateable value; the excise duty was to be greatly increased; the licensee was invariably to reside on the premises; and a special police for the inspection of licensing houses was to be provided." These conditions being complied with, no licence was refused. This experiment was made the subject of inquiry by Mr Villier's select committee of 1854. That committee, which included Sir George Grey and Lord Sherbrooke (Mr Lowe), reported unanimously in its favour. A similar experiment was made in Liverpool during the years 1862-66 without evil results, and also since 1862 in the Prescott division of the county of Lancashire. On the Continent the only countries where free trade prevails are Belgium, Holland, Greece, Spain, and Roumania. In certain parts of Bavaria communes possess breweries, the produce of which they are by custom entitled to sell without any licence; and the Rhenish Palatinate has never been subject to the restrictions mentioned below which apply to the rest of the empire. In Belgium licences are unknown. The only tax which the publican pays is the "patent" which is paid by every trade. So strong is the general law in Belgium that in 1866, when the municipal authorities of Antwerp issued a regulation prohibiting the sale of alcoholic drinks in the streets, this was held to be illegal by the court of cassation. The Dutch law is the same as in Belgium. It must not be supposed, however, that the Dutch are satisfied with the present law. The Dutch "society for total abstinence from strong drink" is very active; and in 1880 the Government presented to the lower chamber a bill, introducing a licence and also the principle of the normal number, the proportion of licences to population varying according to the total population of towns. In Belgium the *Association contre l'abus des boissons alcooliques* is endeavouring to secure amendments of the law, chiefly of a fiscal and police character, but the introduction of the licence is not suggested. In Germany, with the ex-

ception of Würtemberg and those places where the licence is unknown, the liquor trade is practically free. The law of 1869 declares that a licence can be refused for two reasons only— if the police condemn the structure or situation of the premises, or if the applicant is likely to encourage drunkenness, gaming, resort of theft, or improper meetings. This system may be contrasted with those of Italy and Russia. In Italy, under the law of 20th March 1865, a licence is obtained from the sub-prefect or *autorità politica del circondario* on the demand of the syndic (*sindaco*) of the commune and after consulting with the municipal *giunta*. In Russia, under the decree of 1861 and the communal law of 28th June 1870, the licence is got from the municipal or communal council, or, in certain cases, from the owners of land, especially church land. In both countries the licensing authorities have unlimited discretion, which they have exercised so as to multiply public houses enormously. Assuming that sufficient guarantees can be got for the respectability of the applicant and the good sanitary condition of his premises, the system of free trade, or of unrestricted licensing on defined conditions, is the only one which can be defended on principle. It is impossible for the magistrates to exercise a just discretion in deciding what public-houses are required for a locality. The fact that an applicant has invested capital in the business and is ready to begin is the best evidence that there is a demand to be supplied. There is, however, no prospect of free trade being established in the United Kingdom. The select committee of 1879 reported against it.

A larger number of licensing reformers support the scheme for introducing the "normal number" to the United Kingdom. This was embodied in the bills of Sir Robert Anstruther and Sir Harcourt Johnstone (1876). No new licences were to be granted till the number had been reduced to 1 in 500 of the population in towns, and 1 in 300 in country districts. At present the proportion is 1 to 173 of the population in towns in England and Wales. It seems impossible to determine any such proportion *ab ante*. Even were it possible, the rough classification of towns by population, and the failure to discriminate between various rural districts, would result in great injustice. In Mr Cwen's bill of 1877 and Lord Colv Campbell's bill of 1882 it was proposed to have in each locality a separate licensing board elected annually by the ratepayers. This proposal sins against the recognized principle in the reform of local government that authorities must be consolidated, not multiplied. The select committee of 1879 suggested that the function of licensing might be entrusted to the proposed representative county boards.

Another scheme, which has the advantage of appealing to modern experience in Europe, was contained in Sir Robert Anstruther's bills of 1872 and 1874 and Mr Chamberlain's bill of 1877. These were all modifications of the Gothenburg system, which Mr Carnegie, a Scotch brewer in Gothenburg, has done much to make known in the United Kingdom. In Sweden, prior to 1855, there was absolute free trade in liquor. The General Licensing Act, passed in that year, gave power to local authorities, subject to confirmation by the provincial governor, to fix annually the number of licences, and to sell them for three years on certain conditions. If a company, or "bolag," were formed for the purpose of taking all the licences, the local authority might contract with the company for three years. The Act did not apply to beer. The result of this Act has been twofold. In rural districts almost no licences have been issued. In towns, on the other hand, drinking has increased of late, and has led to the severe police laws of 18th September 1874 and 15th October 1875. In 1866 Gothenburg set the example of transferring the whole public house traffic to a bolag, which undertakes to appropriate no profit

<sup>1</sup> See Cooley, *On Constitutional Limitations*, and *On Taxation*, p. 403; Dillon, *On Municipal Corporations*, i. p. 392; and the recent case of *Boyd v. Bryant*, 37 Amer. Rep. 6. In some States it has been attempted to prohibit indirectly by raising enormously the licence fee. The subject is frequently before the courts, and it has been decided that where the licensing power is given for revenue purposes there is no limit to the discretion of the licensing authority, but where it is given for purposes of regulation the fee should not exceed the expense of issuing the licence and inspecting and regulating the licensed trade.

strangers; the shops present little display, and are ill furnished with wares. The markets are tolerably well supplied with meat, fish, and country produce. A large quantity of excellent fruit is brought in for sale during the season.

The king usually resides at the palace of Ajuda, situate on a hill above the suburb of Belem. It is in the Italian style, and was intended to be one of the largest palaces in Europe, but it has been left incomplete. It contains a large library, a collection of pictures, and a numismatic cabinet. There is another royal palace at Lisbon (that of the Necessidades), where former monarchs were wont to reside; and in the neighbourhood of the city are numerous others. Several of the nobility have good and spacious houses in

The houses of the British residents are mostly to be found in the elevated district called Buenos Ayres.

Two or three small forts, one on a rock at the mouth of the Tagus, afford a very inadequate defence against the attacks of a hostile fleet. In ascending the river the picturesque Tower of Belem, built about the end of the 15th century, is seen on the north bank close to the water's edge. On a rocky hill stands the citadel of St George, surrounded by the most ancient part of Lisbon, composed of narrow tortuous streets, still retaining its old Moorish name, Alfama. The chief naval and military arsenals of the kingdom are at Lisbon. Attached to the former are a naval school and a hydrographical office. Here also is a museum of colonial products. In various parts of the city are barracks for the accommodation of the

FIG. 1. Plan of Lisbon.

troops and for the municipal guard. The churches are numerous, but are nearly all in the same tasteless Italian style; the interiors, overlaid by heavy ornament, contain pictures utterly devoid of merit. The cathedral is gloomy without being grand, but the oldest part behind the high altar may deserve inspection. The largest church in the city is St Vincent's, 222 feet by 82. The large adjacent convent is now the residence of the cardinal patriarch. In a modern chapel attached to the church the confined corpses of the monarchs of the house of Braganza are deposited, and the public are admitted to see them on certain days in the year. Perhaps the most striking church in Lisbon itself is that of the Estrela, with a dome commanding an extensive view, and two towers, the whole design reminding the visitor of St Paul's, London. At St Roque is the famous chapel of St John

the Baptist, designed by Vanvitelli, and made at Rome for King John V., who had been enriched by the discovery of the gold and diamond mines in Brazil. Before being sent to Portugal it was set up in St Peter's, and Benedict XIV. celebrated the first mass in it. It is composed of precious marbles with mosaics and ornaments in silver and bronze, and is said to have cost upwards of £120,000. By far the most interesting architectural object at Lisbon is, however, the unfinished Hieronymite church and monastery at Belem. The church was begun in 1500 near the spot where Vasco da Gama had embarked three years before on his famous voyage to India. The style is a curious mixture of Moorish Gothic and Renaissance, with beautiful details. The English college was founded in 1628 for the education of British Roman Catholics; and the Irish Dominicans have a church and convent originally established for the education

tion of youths intended for the priesthood. Ecclesiastically Lisbon is a patriarchate, the holder of the dignity being at the head of the clergy of the kingdom, and president of the chamber of peers. He is usually made a cardinal.

The two chambers of parliament hold their sittings in a huge building, formerly the monastery of St Bento, to which a handsome façade has been added. New and ornamental buildings have been erected for the courts of justice and the municipal chamber. The mint is fitted up with steam machinery on a small scale for coining gold, silver, and copper. Postage stamps and inland revenue stamps are printed at this establishment. The national astronomical observatory is near the Ajuda palace, and the meteorological observatory is at the Polytechnic school, which also contains the national museum of natural history. Here is a good collection of the birds of Portugal, with collections in other branches of the zoology of Portugal and the Portuguese possessions in Africa—minerals, fossils, &c. The fossils collected by the Geological Commission to illustrate the geology of the kingdom are preserved in the sequestered Convento do Jesus.

Lisbon is singularly destitute of works of high art. The gallery of the Academy of Fine Arts contains only a few pictures worth notice. In the custody of the academy is an interesting assemblage of gold and silver plate taken from suppressed monasteries. There is also a collection of pictures at the Ajuda palace. At the Carmo church is an archaeological museum. The great national library consists for the most part of old theological works and ecclesiastical histories swept out of various suppressed monasteries, and has a collection of 24,000 coins with some Roman bronzes. The Portuguese take little interest in literature, art, or science, and almost everything connected with them is in a neglected state. Literary and scientific societies are few in number and badly supported, the principal one being the Royal Academy of Sciences, founded in 1779. The national printing office, a Government establishment, turns out creditable work, but the booksellers' shops are few and ill-stocked. Eight or ten daily journals are published in Lisbon, and there are a few weekly newspapers, besides periodicals appearing at longer intervals, and chiefly devoted to special interests.

Several cemeteries have been constructed of late years near Lisbon, the practice of interring in churches having been abandoned. In the English cemetery lies the English novelist Fielding, who died here in 1754; a marble sarcophagus with a long Latin inscription covers his remains. The British residents maintain a chaplain who performs service regularly in an adjacent chapel, and the Scottish Presbyterians have also a place of meeting. The great hospital of S. José contains beds for nine hundred patients, and the large lunatic asylum has accommodation for four hundred patients. The Foundling Hospital takes in more than two thousand children annually. At Belem is an excellent establishment where a large number of male orphans and foundlings are fed, clothed, educated, and taught various trades. The Lazaretto is a vast building on the south side of the Tagus, where one thousand inmates can be received at one time.

Lisbon is connected by railway with Madrid, and there is also a line northward to Coimbra and Oporto, as well as lines southward to Setúbal, Évora, and Beja. Submarine cables connect it with England and with Brazil. There is communication by regular lines of steamers with the Portuguese islands in the Atlantic and the colonies in Africa, and with a great number of ports in Britain, continental Europe, and other parts of the world. Lisbon is the largest port in the kingdom, and its custom-house is a spacious and very substantial fire-proof building worthy of any capital in Europe, in which merchants are allowed to

deposit their goods free of duty for a year, or for two years in the case of Brazilian produce. The duties annually collected here exceed £1,150,000, tobacco alone producing £400,000. Upwards of 1400 foreign vessels, and about 1100 Portuguese ships, including coasters, enter the port annually. The annual imports amount to about £5,600,000, and the exports to £4,500,000. A considerable number of foreign merchants reside in Lisbon, and there are about fifty British firms. The most active commerce is carried on with Brazil and Great Britain, tropical produce being

FIG. 2.—Port of Lisbon.

imported from the one, and manufactured goods from the other, while wine and oil are sent to both in return. The wine for exportation is all made and stored outside the city bounds, so as not to be subject to the octroi duty. There are several joint-stock banks, one of them being British (the New London and Brazilian Bank), as well as private bankers. Manufactures are carried on only to a limited extent. The largest establishment by far is the tobacco manufactory, where 1600 persons are employed, and three millions of pounds are annually manufactured.

The chief supply of water for the use of the city is brought by an aqueduct 9 miles in length, from springs situated on the north-west. This work, one of the boasts of Lisbon, was completed in 1738, and was so well executed that the great earthquake did it no injury. It crosses the Alcantara valley on thirty-five arches, the principal one being 263 feet above its base, with a span of 110 feet. On reaching the city the water is conducted into a covered massive stone reservoir, which an inscription styles "urbis ornamentum orbis miraculum," and thence it flows to the fountains, thirty-one in number, distributed throughout the city. From these fountains it is removed in barrels to the houses by "Gallegos," men from Galicia, who do the principal part of the hard work in Lisbon. Although there are two other reservoirs near the city, the supply of water is insufficient for the requirements of the place during the warm season.

For municipal purposes the city is divided into four districts (*barras*), the whole under one municipal chamber, and two suburban districts under separate chambers. The city chamber consists of twelve members elected by the burgesses every two years. Its revenue is about £75,000. The octroi duties, levied on provisions and fuel entering the city, are collected on account of the Government, and exceed £270,000 a year. The police force is paid by the Government, and consists of the municipal guard, a military force of cavalry and infantry under the orders of the home secretary, and a body of ordinary policemen at the orders of the civil governor, an official appointed by Government. According to the census of 1878 the population in the thirty-nine parishes of the city and suburbs was 253,000.

*Climate.*—Notwithstanding the mildness of the climate, Lisbon is not considered a healthy place of residence, owing chiefly to the defective sanitary arrangements. The annual death-rate is 86 per thousand. The deaths are said to exceed the births, and the population would therefore decrease were the city not continually recruited from the country. To chest invalids it is not by

any means to be recommended as a winter resort, on account of the frequent and rapid changes of temperature to which it is subject. These changes, and the great difference between the temperature of sun and shade during the winter and spring, are dangerous to the delicate. In summer the heat is great, and all who have the means betake themselves during that season to Cintra or to the seaside. The following data, deduced from twenty years' observations (1856 to 1875) taken at the Meteorological Observatory, a well-managed institution which stands 335 feet above the level of the sea, will afford the means of judging the climate in its principal features. Mean annual temperature of shade, 60°·37 Fahr.; mean annual range, 61°·2; mean daily range, 12°·6; highest and lowest registered during the whole period, 98°·8 and 30°·3. Mean annual quantity of rain, 28·84 inches; greatest and least annual quantity during the period, 38·8 inches (1865) and 17·22 inches (1874). The rainfall of 1876, however, amounted to 45 inches, more than one-third of which fell in the month of December. The mean annual number of days on which rain fell was one hundred and twelve, whilst snow fell only three times during the twenty years. The mean atmospheric moisture (100=saturation) was 70·89. The mean annual height of the barometer was 29·8 inches, and its mean annual range 1·3 inches. The prevailing winds of the winter and autumn are from the north, of the spring and summer from the north-north-west.

**History.**—The name Lisbon (Portuguese, *Lisboa*) is a modification of the ancient name *Olisipo*, also written *Ulyssippo* under the influence of a mythical story of a city founded by Ulysses in Iberia, which, however, according to Strabo, was placed by ancient tradition rather in the mountains of Turdetania. Under the Romans *Olisipo* became a municipium with the epithet of *Felicitas Julia*, but was inferior in importance to the less ancient *Emerita Augusta* (Merida). After the Romans the Goths and the Moslems successively became masters of the town and district. Under the latter the town bore in Arabic the name of *Lashbūna* or *Oshbūna*. It was the first point of Moslem Spain attacked by the Normans in the invasion of 844. When Alphonso I. of Portugal took advantage of the decline and fall of the Almoravid dynasty to incorporate the provinces of Estremadura and Alemtejo in his new kingdom, Lisbon was the last city of Portugal to fall into his hands, and yielded only after a siege of several months (21st October 1147), with the aid of English and Flemish crusaders who were on their way to Syria. In 1184 the city was again attacked by the Moslems under the powerful caliph Abu Ya'kub, but the enterprise failed. In the reign of Ferdinand I., the greater part of the town was burned by the Castilian army under Henry II. (1373), and in 1384 the Castilians again besieged Lisbon, but without success. Lisbon became the seat of an archbishop in 1390, the seat of government in 1422. It gained much in wealth and splendour from the maritime enterprises that began with the voyage of Vasco da Gama (1497). The patriarchate dates from 1716. From 1586 to 1640 Lisbon was a provincial town under Spain, and it was from this port that the Spanish Armada sailed in 1588. In 1640 the town was captured by the duke of Braganza, and the independence of the kingdom restored. For many centuries the city had suffered from earthquakes, of more or less violence, but these had been almost forgotten when, on the 1st of November 1755, it was reduced almost in an instant to a heap of ruins. A fire broke out to complete the work of destruction, and between 30,000 and 40,000 persons lost their lives. Pombal, an unscrupulous minister, but a man of great talent, applied himself with unremitting energy both to the protection of the rights of property (for the place was infested by bands of robbers) and to the reconstruction of the buildings. The handsomest part of the present city was erected under his direction, but even to this day there are edifices which speak forcibly of the great earthquake. In 1807 Napoleon proclaimed that the house of Braganza had ceased to reign in Europe, whereupon the regent Don John (his mother the reigning queen Maria I. having become insane) thought it prudent to quit the country for Brazil, and next day a French army under Junot entered the city, possession of which he retained for ten months. He then quietly embarked his army under the protection of the inexplicable convention of Cintra so disgraceful to the English generals. In 1859 Lisbon was stricken by yellow fever, and many thousands were carried off before the plague was stayed. Lisbon boasts of having been the birthplace of St Anthony, surnamed of Padua, of Camoens, the national epic poet (to whose honour a bronze statue has been placed in one of the squares), and of Pope John XXI. (J. Y. J.)

**LISBURN**, a market-town, cathedral city, and municipal and parliamentary borough of Ulster, Ireland, partly in Antrim and partly in Down, is situated in a beautiful and fertile district on the Lagan, and on the Ulster Railway, 8 miles south-south-west of Belfast. It is substantially built, and consists principally of one long and irregular street, in the centre of which there is a large open space for the market. The parish church, which possesses a fine

octagonal tower, is the cathedral church of the united dioceses of Down, Connor, and Dromore, and contains a monument to Jeremy Taylor, who was bishop of the see. Among other buildings are the court-house, the market-house, the linen hall, and the county infirmary. There are a number of charitable foundations. The staple manufacture of the town is linen, specially damasks and muslins. There are also bleaching and dyeing works. The population in 1871 was 9326, and in 1881 it was 10,834.

In the reign of James I. Lisburn, which was then known as Lisnegrivy, was only an inconsiderable village, but in 1627 it was granted by Charles I. to Viscount Conway, who erected the castle for his residence, and laid the foundation of the prosperity of the town by the introduction of English and Welsh settlers. In November 1641 the town was taken by the insurgents, who on the approach of superior numbers set fire to it. The troops of Cromwell gained a victory near the town in 1648, and the castle surrendered to them in 1650. The church was constituted a cathedral by Charles II., from whom the town received the privilege of returning two members to parliament, but since the Union it has returned only one.

**LISIEUX**, capital of an arrondissement in the department of Calvados, France, 113 miles by rail west-north-west from Paris, and 24 miles as the crow flies east from Caen, is prettily situated on the Touques, at the point where it is joined by the Orbiquet, 24 miles above Trouville. The Paris and Caen Railway has a branch from Lisieux to Honfleur and Trouville, and another to Orbec. The cathedral church, dedicated to St Peter, founded about 1015, and finished in 1233, which has recently been restored, is the most interesting specimen to be found in Normandy of the transition from the Roman to the Ogival style. It is 360 feet in length, 90 in breadth, and 65 in height; the south tower rises to 230 feet. The nave is remarkable for harmony of proportion, purity of design, and unity of style. The church of St Jacques, built at the end of the 15th century, contains some beautiful glass of the Renaissance, some remarkable woodwork and old frescoes, and a curious picture on wood, restored in 1681. The old episcopal palace (Lisieux ceased to be a bishopric in 1801) near the cathedral is now used as a court-house and prison. In the court house is a beautiful hall called the *Salle Dorée*. The town still retains quaint examples of the wooden houses of the 14th, 15th, and 16th centuries; and there are some elegant modern villas. It also possesses a charming public garden and a small museum. The confluence of the two rivers renders it subject to disastrous inundations; but its commerce and industry cause it, notwithstanding, to rank among the richest towns of Normandy. There is a large cattle trade, and the arrondissement has nearly three hundred factories, employing about ten thousand workmen in the manufacture of cloth and cretonnes. Connected with this industry are numerous spinning-mills, bleach-fields, and dye-works; and there are besides wool-mills, chemical works, tanneries, saw-mills, and the like, which bring up the trade of Lisieux to an annual aggregate of upwards of 50 million francs. The population in 1876 was 18,400.

In the time of Cesar, Lisieux, by the name of *Noviomagus*, was the capital of the Lexovii. Though destroyed by the barbarians, by the 6th century it had become one of the most important towns of Neustria. Its bishopric is said to date from the 3d or 4th century. In 877 it was pillaged by the Normans; and in 911 we find it included in the duchy by the treaty of St Clément. Civil authority was exercised by the bishop as count of the town. In 1136 Geoffrey Plantagenet laid siege to Lisieux, which had taken the side of Stephen of Blois. The war lasted five years, and ended Lisieux and its neighbourhood to the driest extremities of famine. In 1152 the marriage of Henry II. of England to Eleanor of Aquitaine, which added so largely to his dominions, was celebrated in the cathedral. Thomas a Becket took refuge here, and some of his relics used by him are still shown in the hospital chapel. Philip Augustus and reunited to France in 1203, the town was a frequent subject of dispute between the contending parties during the Hundred Years' War, the religious wars, and those of the League.

Among the bishops of Lisieux may be mentioned Nicholas Oresme, who died in 1382, and Pierre Cauchon, the judge of Joan of Arc, who occupied this see after he had been driven from that of Beauvais.

**LISKEARD**, anciently **LISCARRET**, a market-town and municipal and parliamentary borough in the county of Cornwall, England, is picturesquely situated, partly in a hollow and partly on a rocky eminence, 12 miles east of Bodmin, and 26½ west-south-west of London by rail. The church of St Martin, in the Perpendicular style, with a tower of earlier date which possesses a Norman arch, is the largest ecclesiastical building in the county, except the church of Bodmin. A town-hall in the Italian style was erected in 1859. A grammar school was founded at a very early period, and there are several other schools and charities. There are manufactures of leather, but the prosperity of the town is dependent chiefly on agriculture, and the neighbouring tin, lead, and copper mines. Liskeard returns one member to parliament. It received its first charter in 1210, from Richard, earl of Cornwall, brother of Henry III., but its principal charter in 1586, from Queen Elizabeth. The population of the municipal borough (area 810 acres) in 1871 was 1760, and in 1881 it was 1179, that of the parliamentary borough (area 8387 acres) in the same years being 6576 and 5591.

**LISLE**, **JOSEPH NICOLAS DE** (1688-1768), astronomer, was born at Paris on April 1, 1688, and was educated at the Collège Mazarin. His devotion to astronomy dates from 1706, in which year he carefully observed an eclipse of the sun. In 1714 he was admitted to the Academy of Sciences, and in 1720 he made the proposals for determining the figure of the earth, which were carried out under the auspices of that body some years afterwards. In 1721 De Lisle visited England, where, through Newton and Halley, he was received into the Royal Society, and in 1726 he accepted an invitation from Catherine I. to the chair of astronomy in the Imperial Academy of Sciences at St Petersburg. In 1747 he returned to Paris, and was allowed a very imperfect observatory in the Hotel Clugny, where Messier and Lalande were among his pupils. In 1753, previous to the transit of Mercury, he published a map of the world representing the effect of that planet's parallaxes in different countries, and in 1754 he was made geographical astronomer to the naval department. In 1762 he resigned in favour of Lalande, and withdrew to the abbey of Sainte Genevieve, where he died of apoplexy on September 11, 1768.

Besides many other papers contributed to the *Travels* of the Academies of Paris, Berlin, and St Petersburg, he wrote *Mémoires pour servir à l'histoire naturelle et civile de l'île de la Guinée, de la Géographie, et de l'Économie* (St Petersburg, 1747), *Éléments de géographie, astronomie, et autres sciences* (Paris, 1749) (Berlin, 1754), and *Tableau géographique, politique, et commerciale de l'Asie* (St Petersburg, 1755).

**LISMORE**, an island of 3600 acres, about 10 miles long and averaging 1½ miles broad, with a population in 1881 of 630, lying south-west and north-east at the entrance of the Linnhe Loch in Argyll-shire, Scotland. The name means the great enclosure (whether "garden," as the Scotch, or "fort," as the Irish authorities suppose, is uncertain), and occurs in Ireland in the Waterford Lismore and ten other places. "Lis" is one of the most frequent words in compound Irish names, there being one thousand four hundred townlands or villages which begin with it. A Columban monastery was founded there by St Moluag about 592 (Reeves, *Abbeys*, p. 34), whose bell is perhaps that found in 1814 at Kilmichael Glassary,<sup>1</sup> and whose crozier or staff is in the possession of the duke of

Argyll.<sup>2</sup> About 1200 the see of Argyll was separated from Dunkeld by Bishop John "the Englishman," and Lismore soon after became the seat of the bishop of Argyll, sometimes called "Episcopus Lismoriensis" (Skene, *Celtic Scotland*, ii. p. 408 sq.), quite distinct from the bishop of the Isles (Sudreys and Isle of Man), called "Episcopus Sodorienensis" or "Insularum," whose see was divided into the English bishopric of Sodor and Man and the Scottish bishopric of the Isles in the 14th century (Keith's *Catalogue*, p. 173). The monastic establishment of Lismore, at one time consisting of Culdees (Reeves, *Culdees*, p. 49), was converted into a chapter of canons regular and a dean, whose right to elect the bishop was recognized as early as 1249 (Baluze, *Miscel.*, vii. p. 442; *Orig. Paroch. Scot.*, ii. pt. 1, p. 161).

Lismore has an accidental celebrity from the *Book of the Dean of Lismore*, a MS. collection of poems, Gaelic and English, made by James McGregor, vicar of Fortingall and dean of Lismore (1514-51). A selection of the Gaelic poems, with translations by Rev. T. McLachlan, and introduction by Mr W. F. Skene, published 1862, is of value both for the language and the contents. The language is the Gaelic of the West Highlands, spelt phonetically, as spoken in the beginning of the 16th century, and its variations from ancient Irish on the one hand and modern Gaelic on the other are of much interest to Celtic scholars. Its contents are Ossianic fragments, some of Irish, others of Scotch origin, and a few more recent Gaelic verses. The publication of this work, and J. F. Campbell of Islay's collection from old sources of the existing traditional Gaelic poetry, have for the first time given a genuine historical solution of the Ossianic problem (see *Ossian*). There are remains of three castles on Lismore: at Trefort a fort of two concentric circles of dry stones, supposed to be Norse or Danish; at Achindown a square keep with walls 49 feet high, believed to be the palace of the bishop; and on the west side of the island Castle Corlin, mentioned in a grant to Campbell of Glenurquhay in 1470 (*Orig. Par. Sc.*, ii. p. 109).

**LISMORE**, a market-town and seat of a diocese, partly in Cork but chiefly in Waterford, Ireland, is beautifully situated on a steep eminence rising abruptly from the Blackwater, 40 miles west-south-west of Waterford. At the verge of the rock on the western side is the old baronial castle, erected by King John in 1185, which was the residence of the bishops till the 16th century. It was besieged in 1611 and 1643, and in 1645 it was partly destroyed by fire. To the east, on the summit of the height, is the cathedral of St Carthagh, erected in 1663 by the earl of Cork, in the Later English style, with a square tower surmounted by a tapering spire. There are a grammar school, a free school, and a number of charities. Some trade is carried on by means of the river, and there is a salmon fishery. The population of the town in 1871 was 1946.

The original name of Lismore was Maghsaiath. Its present name was derived from a monastery, founded by St Carthagh in 633, which became so celebrated as a seat of learning that it is said no less than twenty churches were erected in its vicinity. In the 9th and beginning of the 10th centuries the town was repeatedly plundered by the Danes, and in 978 the town and abbey were burned by the Ossorians. Henry II., after landing at Waterford, received in Lismore castle the allegiance of the archbishops and bishops of Ireland. In 1518 the manor was granted to Sir Walter Raleigh, from whom it passed to Sir Richard Boyle, afterwards earl of Cork. From the earls of Cork it descended by marriage to the dukes of Devonshire. It was incorporated as a municipal borough in the time of Charles I., when it also received the privilege of returning members to parliament, but at the Union it was disfranchised, and also ceased to exercise its municipal functions. Lismore is the birthplace of Robert Boyle, but its claim to be the birthplace of Congreve does not rest on a sufficient foundation.

**LISZA** (in Polish, *Leszna*), a manufacturing town in the circle of Fraustadt, district of Posen, Prussia, is situated on the Breslau and Posen Railway, near the frontier of Silesia. The most prominent buildings are the handsome château, the mediæval town-house, the three churches, and the synagogue. Its manufactures consist chiefly of cloth, liqueurs, tobacco, and wax; it also

<sup>1</sup> Anderson, *Scotland in Early Christian Times*, 1st ser., p. 206, where it is figured.

<sup>2</sup> See *Orig. Paroch. Scot.*, where it is figured.

possesses several tanneries and a large steam flour-mill, and carries on a brisk trade in grain, cattle, spirits, wine, and furs. The population in 1880 was 11,758, including 3810 Roman Catholics and 1833 Jews.

Lissa owes its origin to a number of Moravian Brothers from Bohemia, who were banished by the emperor Ferdinand I. in the 16th century, and found a refuge on the estate of the Polish family of Leczynski. Their settlement received municipal rights in 1548. During the Thirty Years' War the population was reinforced by other refugees, and Lissa became an important commercial town, and the chief seat of the Moravian Brothers in Poland. COMENIUS (*q.v.*) was long rector of the celebrated Moravian school there. Lissa was twice burned down (in 1656 and 1707) during the Swedish and Polish wars.

LISSA (*Lat.*, *Issa*; *Slav.*, *Vis*), an Austrian island in the Adriatic, 9 miles long, with a greatest breadth of 4 miles, is situated 41 miles from the coast of southern Dalmatia, almost due west of the mouth of the Narenta, in 43° 1' N. lat. and 16° 6' E. long. "The shape is a long parallelogram with two breaks, the Porto di S. Giorgio (one of the finest harbours of refuge in the Adriatic) on the eastern short side, and the Vallone di Comisa contained between two long prongs stretching due west and south-west. The outer walls are stony ridges rising from 170 to 610 feet above sea-level, and declining quaquaversally to the fertile plateau which, averaging 400 feet high, forms the body of the island. The apex is Monte Hum, a bald and flattened cone (1868 feet) on the south-west" (Burton). Wine-growing (for which Issa was famous of old) still forms the principal means of subsistence, an average season yielding from 70,000 to 80,000 barrels; but the sardine fishery (15,000 to 25,000 barrels per annum) is of growing importance, and the peasants distil about 24,000 lb of rosemary oil annually. The island is divided into two communes, Lissa and Comisa. In the former is the chief town, Lissa, with the palace of the old Venetian counts Gariboldi, the former residence of the English governor, the monastery of the Minorites, and at a little distance to the west the ruins of the ancient city of Issa. The population, 6485 in 1869, was 7871 in 1880.

Issa is said to have been settled by people from Leobos, the Issa of the Argonauts. The Parians, assisted by Dionysius the Elder of Syracuse, introduced a colony in the 4th century B.C. During the First Punic War the Issaans, with their beaked ships helped the Roman Buquias; and the great republic, having defeated the Carthagenians against the attacks of Agron of Illyria and his queen Teuta, again found them faithful and serviceable allies in the war with Philip of Macedonia. As early as 996 we find the Venetians in possession of the island, and, though they retired for a time before the Ragusans, their power was effectually established in 1278. Velo Seta, which by that time had become the chief settlement, was destroyed by Ferdinand of Naples in 1484, and by the Turks in 1571. The present city arose shortly afterwards. During the Napoleonic wars Lissa was occupied by the French, but the English defeated their squadron in 1810, and kept possession of the island till July 1815, erecting fortifications (dismantled in 1870) and making it a centre of operations. In 1866 the Italians under Persano made an attack on Lissa, but were defeated by the Austrians under Tegetthoff—the battle being fought about 10 miles north of the harbour.

See Wilkinson (1848); Neale (1861); Brackenbury, in the *Times*, August 11, 1866; *Revue marit.* et col., 1867; and Burton in *Journ. R. G. Soc.*, 1859.

LISTON, JOHN (1776–1846), comedian, was the son of a watchmaker in Soho, London, where he was born in 1776. While the teacher of a day school near Leicester Square, he began to take part in private theatricals, and soon conceived a passion for the stage. He made his debut at a small theatre in the Strand, and shortly afterwards obtained an engagement at Dublin theatre, where, although he adopted tragedy as his role, his natural talent for acting attracted the attention of Stephen Kemble, who engaged him for his theatre at Newcastle-on-Tyne. Discovering accidentally that his forte was not tragedy but comedy, Liston displayed in his personation of old men and country boys a fund of drollery and humour which proved irresistible. An introduction to Charles Kemble led to his

appearance at the Haymarket in 1805 as Zekiel Homespun, and from this time he occupied an unrivalled position in his own line of performance, his broad humour being tempered by true artistic finish, while he possessed an original power of creation which, with his boundless faculty in the elaboration of absurdities, filled up meagre and commonplace outlines with the characteristics of vivid individuality. Paul Pry, first represented in 1825, and always his most popular part, soon became to many a real personage. Liston played successively at Covent Garden, Drury Lane, and the Olympic, and remained on the stage till almost the close of his life. He died March 22, 1846.

LISTON, ROBERT (1794–1847), an eminent Scottish surgeon, was born on the 28th of October 1794, at Ecclefechan, where his father was parish minister. He commenced the study of anatomy under Dr Barclay in Edinburgh University in 1810, and soon became a skilful anatomist. After eight years' study, he began his career as a lecturer on anatomy and surgery in the Edinburgh School of Medicine; and in 1827 he was elected one of the surgeons to the Royal Infirmary. In 1835 he was invited to fill the chair of clinical surgery in University College, London. He held the appointment until his death, on the 7th of December 1847. Liston was a teacher more by what he did than by what he said. He taught simplicity in all operative procedures; fertile in expedients, of great nerve, and of powerful frame, his name is remembered at the present day as a bold and rapid operator. He inspired all around with confidence, and every one present at his operations felt that the knife in his hands, however rapidly he worked, was guided with skill founded upon knowledge. He was the author of *The Elements of Surgery and Practical Surgery*, and made several improvements in methods of amputation, and in the dressing of wounds.

LITANY. This word (*λατρεία*), like *λήτη* (both from *λάτρω*), is used by Eusebius and Chrysostom, most commonly in the plural, in a quite general sense, to denote a prayer, or prayers, of any sort whatever, whether public or private; it is similarly employed in the law of Arendius (*Col. Th. c.*, xvi. tit. 5, leg. 30), which forbids heretics to hold assemblies in the city "ad litania faciendam." But some trace of a more technical meaning is found in the epistle (*Ep.* 63) of Basil to the church of Neocesarea, in which he argues against those who were objecting to certain innovations, that neither were "Eutanas" used in the time of Gregory Thaumaturgus. The nature of the recently introduced *litana*, which must be assumed to have been practised at Neocesarea in Basil's day, can only be vaguely conjectured, probably they had many points in common with the "rogationes," which, according to Isidorus Apollinaris, had been gradually coming into occasional use in France about the beginning of the 5th century, especially when rain or fine weather was desired, and which, so far as the three fast days before Ascension were concerned, were first definitely fixed, for one particular district at least, by Mamertus or Mamercus of Vienne (c. 450 A.D.). We gather that they were penitential and intercessory prayers offered by the community while going about in procession, fasting, and clothed in sackcloth. Sidonius alludes to the incongruity of men going "castorinus et litanias." In the following century the manner of making *litanias* (*litania facere*) was to some extent regulated by the entire Eastern empire by one of the *Novels* of Justinian, which forbade their celebration without the presence of the bishops and clergy, and ordered that the crosses and the actual processions (in procession) should not be carried elsewhere than in churches, nor be carried by lay persons as were duly appointed to do so. The *Novel* of Orleans (511 A.D.) in its twenty-seventh canon (and by article 1), also forbade the carrying of crosses.

ableness of Christianity from Mr Edwards's Reflections, 1695. (3) *A Second Vindication of the Reasonableness of Christianity*, 1697. (4) *A Paraphrase and Notes on the Epistles of St Paul to the Galatians, First and Second Corinthians, Romans, and Ephesians. To which is prefixed an Essay for the understanding of St Paul's Epistles by consulting St Paul himself*, 1706-7 (posthumous).

III. EDUCATION.—(1) *Some Thoughts concerning Education*, 1693. (2) *The Conduct of the Understanding*, 1706 (posthumous). (3) *Some Thoughts concerning Reading and Study for a Gentleman*, 1706 (posthumous). (4) *Instructions for the Conduct of a Young Gentleman*, 1706 (posthumous). (5) *Of Study* (written in France in Locke's journal, and published in L. King's *Life of Locke* in 1830).

IV. PHILOSOPHY.—(1) *An Essay concerning Human Understanding*, in four books, 1690. (2) *A Letter to the Bishop of Worcester concerning some passages relating to Mr Locke's Essay of Human Understanding in a late Discourse of his Lordship's in Vindication of the Trinity*, 1697. (3) *Mr Locke's Reply to the Bishop of Worcester's Answer to his Letter*, 1697. (4) *Mr Locke's Reply to the Bishop of Worcester's Answer to his Second Letter*, 1699. (5) *A Discourse of Miracles*, 1706 (posthumous). (6) *An Examination of Father Malebranche's opinion of Seeing all Things in God*, 1706 (posthumous). (7) *Remarks upon Some of Mr Norris's Books, wherein he asserts Father Malebranche's opinion of Seeing all Things in God*, 1720 (posthumous).

The following are Miscellaneous Tracts:—(1) *A New Method of a Common Place Book*, 1686 (this was Locke's first article in the *Bibliothèque de Le Clerc*; his other contributions to it are uncertain, except the *Epitome of the Essay*, in 1688). (2) *The Fundamental Constitutions of Carolina* (prepared when Locke was Lord Shaftesbury's secretary at Exeter House about 1673; remarkable for its recognition of the principle of toleration, and published in 1706, in the posthumous collection). (3) *Memoirs relating to the Life of Anthony, First Earl of Shaftesbury*, 1706. (4) *Elements of Natural Philosophy*, 1706. (5) *Observations upon the Growth and Culture of Vines and Olives*, 1706. (6) *Rules of a Society which met once a Week, for their improvement in Useful Knowledge, and for the promotion of Truth and Christian Charity*, 1706. (7) *A Letter from a Person of Quality to his Friend in the Country*, published in 1875 (included by Des Maizeaux in his *Collection of Several Pieces of Mr John Locke's*, 1720), and soon afterwards burned by the common hangman by orders from the House of Lords, was disavowed by Locke himself. It may have been dictated by Shaftesbury.

There are also various writings of Locke first published in the biographies of Lord Haig and of Mr Fox Bourne.

Locke's numerous *Letters* to Thoyard, Limborch, Le Clerc, Guenellon, Molyneux, Collins, Sir Isaac Newton, the first and the third Lord Shaftesbury, Lords Peterborough and Pembroke, Clarke of Chipley, and others, many of them unpublished, are models in their kind. They express the courtesy and humour which were natural to him, and his varied interests in human life. Those to Molyneux and Limborch in particular throw light on the *Essay*, and his works on Toleration and Christianity.

I. It has been truly said that all Locke's writings, even the *Essay on Human Understanding* itself, were "occasional, and intended directly to counteract the enemies of reason and freedom in his own age." This is obviously true of his works on Social Polity, written in an age when the principles of democracy and toleration were struggling with passive obedience and divine right of kings, and when even "the popular assertors of public liberty were the greatest engrossers of it too." The state with Locke was the issue of free contract, and was not a natural organism. That the people, in the exercise of their sovereignty, have the right to govern themselves in the way they judge expedient for the common good, and that the civil government, whatever form it assumes, has no right to interfere with religious beliefs not expressed in actions inconsistent with civil society, is the essence of his political philosophy. He based the ultimate sovereignty of the people on a virtual consent or contract on the part of the people themselves to be so governed. The precise terms of contract, he allowed, might and should be modified by the sovereign people from time to time, in accommodation to ever changing circumstances. He saw that things in this world were in so constant a flux that no society long remained in the same state, and that "the grossest absurdities" must be the issue of "following custom when reason has left the custom." With an English love of compromise in the working of political affairs, he was always disposed towards liberal ecclesiastical concessions for the sake of religious unity and peace, and recommended obedience to the civil magistrate in all indifferent things in worship and government, not otherwise expressly determined by supernatural revelation.

His attack on Sir Robert Filmer in the *First Treatise on Government* was an anachronism, even when it was published; in the democratic principle argued for in the *Second Treatise*, while in advance of the practice of his age, he was anticipated by Aquinas and Bodin, as well as by Grotius and Hooker. His philosophical defence of the social rights of religious beliefs was the most original

and important of his contributions to polity, and the most far-reaching in its ultimate assumptions. Locke had a more modest estimate of human resources, natural and supernatural, for forming true judgments in religion, and a less pronounced judgment of the immorality of religious error, than either the Catholic or the Puritan. The toleration which he spent his life in, arguing for meant a revolution from the absolute to a relative point of view in the theory of knowledge. It was a protest against those who in theology "peremptorily require demonstration, and demand certainty where probability only is to be had." The practice of universal toleration amidst increasing religious differences was the most important application to the circumstances of his own age of the theory about human knowledge which pervaded his *Essay*. This paradox is now a commonplace, and the superabundant argument and irony in the *Letters on Toleration* fatigue the modern reader. The change of opinion is more due to Locke himself than to any one else. The rights of free thought and liberty of conscience had indeed been pleaded for, on various grounds, throughout the century in which he

lived. Henry Taylor, Cudworth, Glanvill, and other philosophical thinkers in the Church of England urged toleration in the state, in conjunction with a wide comprehension in the church, grounds which implied intellectual limitation and even uncertainty in religious matters. Puritan Independents and Baptists, like Owen, Goodwin, and Richardson, whose ideas of ecclesiastical comprehension was dogmatic and narrow, were ready to accept sectarian variety within the state, on the ground that it was possible to have many religions in the land, but only their own form within their sect. The existence of separate Christian nationalities, on the other hand, was the only justification of separate religious societies to the latitudinarian churchmen with whom Locke associated; in each nationality they would have a comprehensive church co-extensive with the nation. Locke went far to unite in a higher principle what was best in the broad Anglican and in the Puritan theories, while he recognized the individual liberty which has ever distinguished the national church of England. (a)

his reasonings for toleration he insists on the fact that all human theologies must consist more of beliefs determined on presumptions of probability than of knowledge founded on what is either self-evident or demonstrable in the light of reason. A profound sense of the limits of human reason was at the bottom of his arguments for a tolerant comprehension by the state and also by the church. He had no objections to a national establishment of some form of religion, provided it was comprehensive enough, and was really the nation organized to promote goodness, and not to protect the metaphysical subtleties by which professional theologians spoil the original simplicity of Christianity. The recall of the national religion to this primitive simplicity, he hoped, would make toleration of nonconformists unnecessary, as few would then remain to ask for it. (b) The speculative, and therefore individually and socially harmless, nature of most persecuted beliefs and forms of worship is another point on which he insists. "No man is hurt because his neighbour is of a different religion from his own, and no civil society is hurt because its members are of different religions from one another." The more various our beliefs are, the more probable it becomes that a complete view of truth may by degrees be reached at last by the human race. In the meantime beliefs in religion concern the individual only and not society. To the atheist alone Locke absolutely refuses toleration, on the ground that the social bonds can have no hold over him, for "the taking away of God dissolves all." If atheism means the denial that reason is the ultimate regulative principle in the universe, then the consistent atheist without doubt "dissolves all," and must reject physical science even, as well as morality, in an absolute negation, so that he is incapable of citizenship as one who is insane. In Locke's own philosophy, as we shall see, the existence of God is represented as demonstrable, but the distinctive articles of Christianity are founded only on presumptions of probability. He argued too against full toleration to the Church of Rome, at least in the circumstances of the age in which the Toleration Act was passed, on the ground of its allegiance to a foreign sovereign. (c) The unfitness of force as a means of sending the light of truth into a human mind is a third argument urged by Locke, founded on the psychology of human understanding. Persecution can only transform a man into a hypocrite; belief must be formed by individual discernment of evidence. Apart from evidence, a man cannot command his own understanding; he cannot determine arbitrarily what opinions he is to hold. Thus all Locke's pleas for a universal toleration resolve at last into a philosophical view of the limits and origins of knowledge.

II. The principles which determined Locke's social polity largely determined his way of looking at Christianity. His "latitudinarianism" was really the result of an extraordinary reverence for truth, and of his perception that in matters of religion knowledge may be sufficient for practice, while it falls far short of demonstration. He insists on referring questions to the reasoning individual, and never loses sight of the reasonableness of Christianity as the only ground on which

the rest. Locke accepted the Scripture as infallible with the reverence of a Puritan, but he did not, like so many Puritans, mean only Scripture as interpreted by himself. Confidence in Biblical infallibility was also combined in Locke with a distrust in the pretensions of "enthusiasm," which predisposed him to regard miracles, as a criterion needed for distinguishing reasonable religious convictions from mere "inclinations, fancies, and strong assurances." Assent in religion as in every thing else he could only justify on the grounds of its evident rationality; "illumination without search, and certainty without proof and without examination," was to him a sign of the absence of the divine spirit. Fanatical confidence that we are right, he would say, is no proof that we are right; when God makes us assent to the truth of a proposition in religion, he either discovers to us its intrinsic rationality by the ordinary means of scientific insight, or offers miraculous signs, of the existence of which we must have sufficiently probable presumption. Reasonableness somehow must at last be our guide. His own faith in Christianity rested on its moral excellence when it is rightly understood in its primitive simplicity, and on the extraordinary signs in nature which he believed to have accompanied its first promulgation. "Even in those books which have the greatest proof of revelation from God, and the attestation of miracles to confirm their being so, the miracles," he says, "are to be judged by the doctrine, and not the doctrine by the miracles." All this sort of argument became commonplace in books about the "evidences" in the 18th century. The *Reasonableness of Christianity* was an attempt to recall religion from verbal reasonings of theological schools, desuative of peace among Christians, to its original simplicity, but it no doubt involved an abatement of its transcendent mystery and ultimate incomprehensibility. The book was probably written to promote a comprehension of the dissenters. All who practically acknowledge the supremacy of Jesus as the Messiah accept all that is essential to the Christianity of Locke, whatever other theological opinions they may individually or collectively add to this only catholic one.

Christian teachers and apologists in the succeeding age, as well as the assailants of Christianity, alike appealed to the *Essay on Human Understanding*, and the catholic tradition of Anglican theology was thus interrupted in the church for more than a hundred years. His own Christian belief, sincere and earnest, was more the outcome of the sort of common sense sagacity which through him moulded the prudential theology of England in the 18th century, than of the nobler elements present in More, Cudworth, and other religious philosophers of the preceding age, or afterwards in Law and Berkeley, Coleridge and Schleiermacher.

III. Locke takes his place in the succession of great writers on the theory and art of Education. His educational writings might be regarded either as an immediate introduction to or as an application of the *Essay on Human Understanding*. In his *Thoughts on Education* imaginative sentiment is never allowed to weigh against prudential utilitarianism; information and mere learning are subordinated to the formation of character and practical wisdom; the part which habit plays in individuals is always kept in view; the dependence of conscious mind, which it is the purpose of education to improve, upon the health of the corporeal organism is steadily inculcated; to make those happy who are undergoing education is a favourite precept; accumulating facts in the memory without using the power to think, and without accustoming the youthful mind to apply reason to the evidence by which individual thoughts must be tested, is always referred to as the cardinal vice in teaching. Wisdom more than learning is what he requires in the teacher. In the knowledge to be communicated he gives the first place to "that which may direct us to heaven," and the second to "the study of prudence, or discreet conduct and management of ourselves in the several occurrences of our lives," which most assists our "quiet-prosperous passage through this present life." The infinity of knowable existence in contrast with the narrowness of human understanding and experience is always in his thoughts. This "disproportionateness" is one reason given for due deliberation in the choice of studies, and for declining those which lie out of the way of a really wise man, however much they may have been favoured by custom. Among these last he warns especially against, "that maze of words and phrases which have been employed only to instruct and amuse people in the art of disputing, and which will be found perhaps, when looked into, to have little or no meaning. . . words being of no value nor use, but as they are the signs of things; when they stand for nothing they are less than ciphers, for, instead of augmenting the value of those they are joined with, they lessen it and make it nothing." Knowledge of what the opinions of other men have been is another study which Locke deprecates. "Truth needs no commendation, and error is not mended by it; in our inquiry after knowledge it little concerns us what other men have thought.

It is an idle and useless thing to make it one's business to study what have been other men's sentiments in matters where reason is only to be judge." Realism and individual rationality are two essential educational principles with Locke. In his *Conduct of the Understanding* the pupil is to be led to the point at which a full view of all that relates to a question "is to be had, and at

which alone a rational discernment of the truth is possible. The uneducated mass of mankind, on the contrary, either "seldom reason at all," or else "put passion in the place of reason," or "for want of large, sound round-about sense" they direct their minds only to one part of the evidence, "converse with one sort of men, read but one sort of books, and will not come in the hearing of but one sort of notions, and so carve out to themselves a little Goshen in the intellectual world, where light shines, and, as they conclude, day blesses them; but the rest of the vast *expansion* they give up to night and darkness, and avoid coming near it." It is a treatise on the wisdom needed for the management of the individual mind, so as that it may overcome the *idola* or common tendencies to error against which Bacon had warned mankind. Hasty judgment, bias, or want of an *a priori* "indifference" to what evidence may require us to conclude, undue regard for authority or love for custom and antiquity, indolence and sceptical despair, are among the states of mind marked by him as most apt to interfere with the formation of our individual thoughts in harmony with the Universal Thought that is latent in nature. The development of vigorous intellect in each person is the aim of this admirable tract.

IV. The *Essay Concerning Human Understanding* contains Locke's Metaphysical Philosophy. It was the first attempt, on a great scale, and in the Baconian spirit, to show the certainty and inadequacy of human knowledge. This enterprise seemed to Locke to hold out the most reasonable hope of a solution of some sort for the perplexities which encompassed every departure out of inquiry.

The Introduction to the *Essay* is the keynote to the whole. The ill fortune of mankind in their endeavours to comprehend themselves and their surroundings is there attributed to the disposition to extend their inquiries into matters beyond the reach of our intelligence, letting their thoughts wander into depths where we can have no footing. "Whereas, were the capacities of our understandings well considered, the extent of our knowledge once discovered, and the horizon found which sets the bounds between the enlightened and the dark parts of things, between what is and what is not comprehensible by us, men would perhaps with less scruple acquiesce in the avowed ignorance of the one, and employ their thoughts and discourse with more advantage and satisfaction on the other." To inquire into "the original, certainty, and extent of human knowledge, together with the grounds and degrees of belief, opinion, and assent," is Locke's own account of the design of his *Essay*. He expressly excludes from his inquiry "the physical consideration of the mind,"—the natural causes (and, one might add, the transcendental reasons) for our conscious experience being what in his own "plain historical method" he might find it to be. He wanted to be able to make a faithful report, based on what he actually found, as to how far a merely human understanding of the universe can extend, to what extent human beings can share in pure knowledge, and "in what cases they can only judge and guess" on grounds of probability. Although his report might show that the knowledge attainable by the individual must be "narrow," and far short of a "universal or perfect comprehension of whatsoever is," it might also convince us that it is "sufficient," because "suited to our individual state." The "light of reason," the "candle of the Lord" that is set up in us, "shines bright enough for all our purposes. If we will disbelieve everything because we cannot certainly know all things, we shall do much as wisely as he who would not use his legs, but sit still and perish because he had no wings to fly." Locke thus opens his *Essay* in a tone which, with a more homely cheerfulness, reminds one in parts of the sublime conceptions of Pascal, and in others of the wise moderation of Bishop Butler. The outcome is that, if it should turn out on investigation that human understanding cannot solve the metaphysical problem of the universe, we may at least find that at no stage of our individual existence are we the sport of chance or of an evil power, that there is a way by which we can secure our final well-being, even within the inexorable causal connexions, conditioned by space and time, with their imperfectly calculable issues, by which we are environed.

The fourth book alone is concerned directly with the professed design of the *Essay*. It has been suggested by Stewart that Locke may have commenced with this book, especially as it contains few references to preceding parts of the *Essay*, so that "it might have been published separately without being less intelligible than it is." The inquiries in the preceding books are of a more abstract and scholastic nature, which probably opened gradually on his mind as he studied his subject more closely. The second and third books both relate to our individual ideas or thoughts. That each person has thoughts, and that without thoughts or consciousness there could be no knowledge for him, is Locke's postulate. This, he presumes, "will be easily granted"; for "every one is conscious of ideas in himself, and men's words and actions will satisfy him that they are in others." Questions about knowledge and its extent therefore presuppose questions about ideas or thoughts. But our mere ideas are, as Locke reminds us, "neither true nor false, being nothing but bare appearances in our own minds." Truth

and falsehood belong only to the assertions or denials of the mind. The idea of a centaur has no more falsehood in it, when it appears in our minds, than the name centaur has falsehood in it when it is pronounced by our mouths, or written on paper. Truth and falsehood lie always in affirmations or negations, and the mere thoughts of which as individuals we happen to be conscious are not *per se* either true or false. They do not become either real knowledge or error "till the mind affirms or denies something of them."

That none of our knowledge is "innate" is the conclusion argued for in the First Book. But the drift of this famous argument has been overlooked by Locke's critics. It has been criticized as if it was a metaphysical discussion about the existence of transcendental elements in human knowledge, like that at issue in the present day between empiricism and intellectualism. If it were so it would be an example of the fallacy of irrelevant conclusion. For this Locke himself is no doubt partly responsible. It is not easy to determine who or what he had in view in this polemic. Lord Herbert alone is made prominent as the defender of innateness, and Locke was perhaps too little read in the literature of ancient and modern philosophy to do full justice to those who, from Plato downwards, have recognized the intuitions of reason as well as the phenomena of sense in the constitution of knowledge. The positions which he assails would have been disclaimed by the most eminent defenders of the transcendental elements. "Innate," as Lord Shaftesbury says, "is a word Mr Locke poorly plays on,"—at least if he is to be understood as engaged in an intellectual struggle against Plato or Descartes. "The right word, though less used, is *connatural*. For what has birth, or the progress of the fetus, to do in this case?" The real question, as Shaftesbury adds, is not about the time when the supposed innate knowledge entered, but "whether the constitution of man be such that, being adult and grown up, the ideas of (rational) order and administration of a God will not infallibly and necessarily spring up in him." But this Locke himself does not deny. "That there are certain propositions," we find him saying, "which, though the soul from the beginning, or when a man is born, does not know, yet, by assistance from the outward senses, and the help of some previous cultivation, it may afterwards come certainly to know the truth of, is no more than what I have affirmed in my first book" (see "Epistle to Reader," in second edition). This further appears from the fact that, although the *Essay* opens with an attack on innateness in human knowledge, yet the self-evidence, in the light of educated reason, of much that we know is asserted elsewhere not less strenuously. Much of our knowledge he reports in the fourth book to be reached by purely rational insight and demonstration. What he really argues against in the first book is that any of it should be supposed to have a claim to protection against a free criticism of its reasonableness. He argues there against the innateness of our knowledge of God and of morality; yet in the fourth book he reports, as a result of his search into our rational consciousness, in the "plain historical method," that the existence of God is a demonstrable rational conclusion, involved in that causal necessity without which there could be no knowledge at all; and he maintains in various places that morality may be found to be as demonstrably necessary as mathematics. The two positions are quite consistent. The demonstrable rational necessity of these and other sorts of knowledge often remains latent, he might say, in the share of reason that is potentially present in individuals, and therefore cannot be called "innate" knowledge; but, for all that, such truths "carry their own evidence along with them" in every mind that is rationally awake. Even in the first book he appeals to what might be called common reason, which he calls "common sense." "He would be thought void of common sense who asked, on the one side, or, on the other, went to give a reason, why 'it is impossible for the same thing to be and not to be.' It carries its own light and evidence with it, and needs no other proof, he that understands the terms assents to it for its own sake, or else nothing else will ever be able to prevail with him to do it" (bk. i. chap. 3, § 4). The truth is neither Locke nor the intellectualists of the 17th century expressed their meaning with enough of precision; if they had, Locke's first book would probably have taken a form more consistent with its true intention. It is really to be read as an energetic argumentative protest against anything in human knowledge being supposed to be independent of rational criticism. Locke believed that in attacking innate principles he was really substituting conscious self-evidence and rational demonstration instead of blind repose on authority, and was thus, as he says himself, not "pulling up the foundations of knowledge," but "laying these foundations surer." Truth is to be found in "the contemplation of things themselves," that is, by actual rational insight on the part of each individual. But when men heard of "some general propositions that could not be doubted as soon as understood," it was a short and easy way to conclude that such propositions are "innate," and that a personal perception of their rational self-evidence is unnecessary. This being once received, "it eased the lazy from the pains of search,

and stopped the inquiry of the doubtful concerning all that was once styled innate." Dogmas became protected against rational criticism. "It was no small advantage to those who affected to be masters and teachers to make this the principle of principles—that principles must not be questioned." The mere assumption that they are "innate" was enough "to take men off the use of their own reason and judgment, and to put them upon believing and taking upon trust without further examination. . . . Nor is it a small power it gives a man over another to have the authority to make a man swallow that for an innate principle which may serve his purpose who teacheth them" (bk. i. chap. 4, § 24). Locke's examination of the way in which the rational consciousness of self-evident truths is actually reached refers them to "the being of things themselves duly considered, and to the application of those faculties that are fitted to receive and judge of them when duly employed." Thus the reasoning which runs through the first book is a return, in a more general and therefore more philosophical way, to that defence of individual rational insight against blind dependence on authority which was offered in the *Letters on Toleration*.

The Second Book opens with the suggestion of a general proposition regarding the genesis and constitution of ideas or thoughts; it closes after a laboured endeavour to verify it. This hypothetical proposition is that all human thoughts, even the most complex and abstract, are due to "experience." If so, the significance of all abstract words, and the objective truth of all individual thoughts, must be tested by the elements of which "experience" consists, and cannot in any instance claim protection against this test.

The important point is what "experience" consists of. Locke says that it all comes either from external sources or from the mind itself; and he promises to show that even our most abstract thoughts, which seem to reach to infinity, may be traced to one or other of these constituents. In his own words, our most "complex ideas" are all made up of "simple ideas," either from without or from the mind; they are due to phenomena of which we are percipient in the five senses, or else due to reflexion upon "the operations of mind." The "verification" of this position, in the central chapters of the second book, is to the effect that even those thoughts which are "most abstruse, how remote soever they may seem from sense, or from any operations of our minds, are yet only such as the understanding frames to itself by repeating and joining together ideas that it had either from objects of sense, or from its own operations about objects of sense," so that even large and abstract ideas are derived from one or other of the two sources (bk. ii. chap. 12, § 8). For this purpose our thoughts of space, time, infinity, power, substance, personal identity, causality, and several others which "seem most remote from the supposed original," are examined one after another, in the "historical plain method," and their complex constitution is resolved into (a) perceptions of things external, through the five senses, or into (b) perceptions of operations of our own minds.

The source of experience which depends upon the five senses Locke calls *sensation*; the other, through which mind is reflectively aware of its own operations, he calls *reflexion*. This last, "though it be not sense, as having nothing to do with external objects," is yet, he says, "very like it, and might properly enough be called internal sense." The suggestion that "sense" might designate both the springs of experience is misleading, when we find in the sequel how much Locke tacitly credits "reflexion" with,—in the way of rational tendencies and intellectual obligations; it may be objected to on grounds like those on which the somewhat analogous employment by Reid and others of "common sense" for common reason has been condemned. They both mean to say that we may call that "sense" in which reason at once carries the light of its own evidence, and does not even admit of external proof. Reason in its own evidence is thus analogous to what sense is popularly assumed to be. The elasticity of Locke's language in explaining his thesis makes the most opposite interpretations of the *Essay* possible, and all we can do is to compare one part with another, and in doubtful cases to give him the benefit of the doubt. His vacillation in the use of words is unfortunate. It was partly caused by a determination to avoid rigid technicality and pedantry. "Sensation" for instance is, in one definition, confined to "impressions or motions made in some part of the body which produce perceptions in the understanding" (bk. ii. 1, § 23); yet, when treated as one of the two springs of experience, it is made equivalent to what philosophers now call *sense-perception*, while "reflexion" turns out to be another name for *self-consciousness*. Accordingly, although the second book is professedly limited to the examination of our ideas or thoughts only, it by implication makes the (pre-visional) assumption that the "ideas" of which we are conscious in "sensation" are at the same time to be regarded as "qualities" of sensible things which in some sort of way exist "without us," and also that the successive "operations" presented in "reflexion" are those of an individual mind, presumed to exist somehow independently of them. Locke thus starts as a *common sense* perceptualist, and likewise relieves himself of the difficulty of having at the outset to show how the data abstracted by each sense are united in real-

things and persons. In order to make his theory work, he begins by assuming a *hypothetical duality* beneath phenomena,—some phenomena referable to external things, others referable to the conscious self,—and in fact confesses that this dual experience is the ultimate fact, the denial of which would make it impossible to speak about the growth and constitution of our thoughts.

In the early chapters of the second book, the "simple" thoughts into which he promises to resolve all possible "complex" ones are arranged in classes. Some of them, he reports, are conditioned "by one sense only," as colour by sight, or heat, cold, and solidity by touch; others "by more senses than one," as space or extension and motion, which are perceivable both by the eyes and by touch; a third class are got from reflexion only, when "the mind turns its view inward upon itself," and by this means we get our ideas of perception or thinking itself, and also of willing, as well as the "modes of these two," such as remembrance, discerning, reasoning, knowledge, faith, &c.; lastly, there are simple ideas which we have both from sensation and reflexion, for instance, our thoughts of bodily and mental pleasures and pains, as well as thoughts of existence, unity, power, and succession. Such, according to Locke, are the elements of the sublimest human thoughts. While the mind is becoming gradually stored with simple ideas like these (which are, however, somehow complex for us, when we "are conscious of them"), we find a growing power to elaborate them for ourselves at pleasure in an almost infinite variety; we are in fact obliged to do this in our tentative endeavours inductively to bring the thoughts of our individual minds into harmony with the actual complexity of thought that is presented to us in the order of nature. "But it is not in the power of the most exalted wit or enlarged understanding to invent or frame any new simple idea not taken in in one or other of these two ways,"—in proof of which Locke would have any one try to fancy any taste which had never affected his palate, or to frame the thought of a scent he had never smelt; and when he can do this he is ready to concede that a born blind man has ideas of colours, and a born deaf man notions of sounds.

The contrast and correlation of these two fountains of individual experience is suggested in the eighth chapter of this book, on the "qualities" of matter, in which we are introduced to a noteworthy vein of speculation running through the *Essay*. A chapter on "qualities of things" looks like an interpolation in an examination of our individual thoughts; its relevancy appears when we remember Locke's provisional hypothesis, according to which simple ideas of sense may also be viewed as qualities of things. Now, our original sense-thoughts are, we find, partly revelations of *external things themselves* in their essential externality or extension, and partly *sensations*, boundless in their variety, which are somehow raised in us through contact with the things. Locke calls the former primary, original, or essential qualities of matter, and the others its secondary or derived qualities. The primary, which involve mathematical relations, and might be called quantities rather than qualities, are inseparable from matter as matter, and somehow exactly correspond, he reports, to the thoughts we have of them. On the other hand, there is nothing in the mathematical relations of space-occupying body which in the least resembles our ideas or thoughts of the secondary qualities; they are qualities of bodies at all, rather than sensations in us, only in so far as our different secondary sensations somehow correlate with (unknown) sizes, shapes, and motions of the primary particles, with which they are thus in an established harmony. Therefore, if there were no sentient and intelligent beings in existence, the secondary qualities would cease to exist,—except perhaps as unknown modes of the primary, or, if not, as "something still more obscure." On the other hand, "solidity, extension, figure, motion, and rest would be really in the world as they are, whether there were any sensible being to perceive them or not" (bk. ii. chap. 21, § 2). The outcome of what Locke teaches about the mutual relations of matter (a) known as occupied-space, and (b) known in and through the sensations caused by secondary or relative qualities, is that it is something capable of being expressed at once in terms of mathematical quantity or extension, and also in terms of sense-consciousness. A further step would have led to the conception of the correlative dependence of all the so-called qualities of bodies upon "the bulk, figures, number, situation, and motions of the solid parts of which they consist," and which "exist as we think of them whether or not they are perceived." The true conception of an individual body would then be a conception of the actual mathematical relations of the atoms of which it consists, regarded as the established "occasions" of the sensations of colour, resistance, sound, taste, or smell which we refer to it as qualities; and also of the changes that it occasions in the atoms of which other individual bodies consist, which are followed by their operating on sentient beings differently from what they did before, as when the sun melts wax. But Locke only suggests in a hesitating way that the powers of bodies which are manifested in sensible changes may be conditioned by unknown changes in the mathematical relations of their insensible atoms, or, if not thus dependent upon them, conditioned by

"something yet more remote from our comprehension." For, not knowing what size, figure, and texture of parts they are on which depend and from which result those qualities which make our complex idea, for example, of gold, "it is impossible we should know what other qualities result from, or are incompatible with, the same constitution of the insensible parts of gold, and so consequently must always coexist with that complex idea we have of it, or else are inconsistent with it."

Some of the most remarkable chapters in the second book are those which relate to the verification of its initial proposition. They carry us towards the metaphysical mysteries which so attract meditative minds. The hypothesis that our most complex thoughts are all resolvable into "experience" is tested in these chapters by the *modes or modifications*, and *substantiations*, and *relations* which, in various degrees of complexity, we find ourselves somehow obliged to make the simple phenomenal thoughts of sense and reflexion undergo. Such, for instance, are the thoughts of finite quantity in space and time and number, in which Locke reports that we find ourselves mentally impelled towards immensity, eternity, and the innumerable, that is to say, towards infinity, which transcends quantity; the complex thought of Substance, towards which he reports that we find ourselves impelled in another of the "operations of our minds," when the simple phenomena of the senses have to be regarded as powers or qualities of "something"; the thought of the identity of individuals, involved in the apparently inconsistent idea of their constant phenomenal changes; and, above all, the mental tendency we find we somehow have to suppose what we call a "Cause" whenever we observe a change. Let us see how Locke deals with these crucial instances.

He dwells much on our ideas of Space, Succession, and Number. The first he says begins to appear when we use our senses of sight and touch; the second he finds "suggested" by all the phenomena of sense, but still more by "what passes in our minds"; the third is "suggested by every object of our senses, and every thought of our minds, by everything that either doth exist or can be imagined." The modifications of which these three sorts of simple ideas are susceptible he reports to be "inexhaustible and truly infinite, extension alone affording a boundless field to the mathematician." In his own patient judicial way, he finds many curious analogies between space and time. Neither is limited by the world of individual things. We can imagine space without bodies, but we cannot perceive or imagine bodies without space. Places and periods are all relative to objects and events, but both space and time are absolutely indivisible. A trinal space extends in all directions, while time has only one dimension. All things exist in the same present time, while no two things occupy the same space. The parts of time cannot be thought to coexist; the parts of space cannot be thought to succeed one another. Whether the thought of unoccupied space is the thought of a substance or of an attribute Locke professes that he cannot tell, at least till they that ask show him "a clear distinct idea of substance." But the real mystery which he has to report of these thoughts of space and time is that "something in the mind" hinders us from imagining any limit to either. We find ourselves, when we try, obliged to lose our positive thought of space in the negative thought of Immensity, and our positive thought of time in the negative thought of Eternity. We have never seen, and we cannot mentally imagine, an object whose extent is boundless. Yet we find when we reflect that there is an "operation of the mind" which somehow forces us to think that space and time *have no limits*. "I would fain meet with that thinking man that *can* in his thoughts set any bounds to space more than he can to duration" (§ 21). Thus Locke by implication acknowledges something added by the mind to the originally presented "simple ideas" of extension and succession, though he explains that what is added is not positively imaginable. When we reflect on our thoughts of immensity and eternity, we find them to be thoughts, yet negations of all imaginable thought; and that whether we proceed by addition or by division. He characteristically accepts the fact; he does not inquire *why* mind should find itself thus obliged to add without limit, and to divide without limit. He simply reports that immensity and eternity are inevitable negative ideas, and that every endeavour to transform them into positive or imaginable ones only issues in the contradictory attempt to represent as a bounded quantity what is really infinite or beyond quantity. The idea of the infinite, or unquantifiable in extent and in succession, has so far, he finds, "something that is resolvable into the simple positive ideas of space and time." For, when we try to think of the infinite in space or duration, we at first usually make some very large idea (imaginable in itself, though by men unimaginable, as perhaps of millions of miles or ages, which possibly we multiply millions of millions of times. All that we thus amass in our thoughts is positive (*i.e.*, imaginable in its nature, although not imaginable by a human mind). But at the end of this we are as far from the infinite reality as we were at the beginning, so that what lies beyond the imaginable idea *towards* the infinite lies "in obscurity, and has the indeterminate confusion of a negative idea,"—irresistible and incomprehensible.

Locke, with all his aversion to what is unrepresentable in forms of coexistence and succession, is too faithful to rational facts to overlook these mysterious elements of our rational experience. His integrity is also illustrated in his acknowledgment of the unimaginable, and in this sense incognizable, in our thought of Substance. He tries to phenomenelize it; but he finds that it cannot be phenomenalized, and yet that we cannot dispense with it. An unsubstantiated succession of phenomena, without a centre of unity to which they are referable, is unintelligible; we could not have a language consisting only of adjectives. Locke had an obscure apprehension of this intellectual obligation as a fact of rational consciousness. According to his report, "the operations of the mind" oblige us to suppose something beyond phenomena, to which as qualities phenomena must belong; but he was honestly perplexed by the "confused negative" thought of this "something," which was all that he could reach, and of which he says we "neither have nor can have any positive idea either by sensation or reflexion." The word substance thus means "only an uncertain supposition of we know not what" (i. 4, § 18). All attempt to realize it is like the attempt to realize immensity or eternity, and we are involved in an endless—inevitable yet incomprehensible—regress. If one were to ask *what* the substance is in which this colour and that taste and smelling "inhere," and was told that they belong to the solid and extended parts, or primary qualities, of the thing, he must again ask what *their* substance is, and so on for ever. "He would be in a difficulty like the Indian, who, after saying that the world rested on an elephant, and the elephant on a broad-backed tortoise, could only suppose the tortoise to rest on 'something, I know not what.'" We must fail, in short, when we try either to phenomenelize our thought of substance or to dispense with it. He finds that our only positive complex ideas of substances are these in which we imagine an aggregate of attributes; it is only thus that we can rise to any positive thought even of God, in "the power we have of enlarging indefinitely some of the ideas we receive from sensation and reflexion" (ii. 23, § 33). *Why* we must be in this strange mental predicament with regard to our thought of substance, Locke characteristically did not inquire. He reported the fact in his own "plain historical way."

He struggled bravely to be faithful to facts in his report of the not unlike mental predicament in which we find ourselves when reflexion awakens in us the conviction of our own individuality and continued personal sameness. The paradoxes of expression in which he gets involved in the chapter on "personal identity" are evidence of this. He mixes the thought of our actual individual personality, given in our consciousness of something external to self, and above all in our moral experience of responsible agency, with the negative thought of the transcendental relation of substance, which, when we try to phenomenelize it, becomes "an uncertain supposition of we know not what."

But we must pass on to his report about our thoughts of Causality and Power, especially as his theory of real knowledge in the fourth book is very much an application of the principle of causality. The intellectual demand for the cause of an event is what we find we cannot help having, and yet it is a demand for what in the end we cannot grasp in a phenomenal representation. The causal thought in the form of power very much perplexed Locke, in his famed chapter on that idea (21); the perplexity is not so obvious in the sections on "cause and effect," in another chapter (26), where he considers only the circumstances in which this relational thought arises.

Locke traces the thought of "cause and effect" back to our "constant observation" that "qualities and finite substances begin to exist, and receive their existence" from other beings which produce them. Seeing, for instance, that, "in the substance which we call wax, fluidity is constantly produced by the application of a certain degree of heat, we somehow come to think of heat as the cause and fluidity as the effect." This is to report what happens in our minds when we observe a particular example of that causal connexion which gives intelligibility to successive phenomena, converting them into the concatenated system which we call the universe. Through calculated observations we, in this way, learn that *this* is the cause of *that*, and that *such* as *this* is the cause of *such* as *that*. But Locke's words in the 26th chapter do not explain the rational need for this causal expectation. Anything, as far as "constant observation" tells us, might have been the cause of anything; no finite number of instances of an "observed" sequence—in the strict meaning of the term "observation"—can guarantee its universality. Elsewhere, indeed, he adds to this meagre account the important statement that "our clearest idea of power is got through our consciousness of our own voluntary agency, and therefore through reflexion" (chap. 21). Bodily phenomena he there reports to be incapable of presenting originaive agency, this being an idea which cannot be phenomenalized in external sense. In changes among bodies we observe no origination, but only phenomenal order—significant and therefore interpretable phenomena. The thought of the "production" of motions is connected with what we are conscious of when we exert volition. Locke here approaches the view of power afterwards taken by

Berkeley, which was the constructive principle of Berkeleyan philosophy. But neither Locke nor Berkeley explains the transformation of our moral consciousness of ourselves, as free or originaive, and therefore, to this extent, responsible agents, into the universal rational principle, on which both proceed in explaining our knowledge of the real existence of God and of the sensible world. Locke's language sometimes suggests that the transformation is made through an induction that is, either instinctive or produced by custom. Now, not to say that every inductive generalization presupposes causal connexion, the particular fact that *this, that; or the other person*, through his moral experience, finds *himself* a free cause, does not, consistently with inductive rules, warrant the universal conclusion that the phenomenal changes of the universe must all be referred to power like our own personal power. That we are somehow obliged to think a caused or phenomenal cause, and ultimately an uncaused or free agent, of every change—that we are obliged to view changes as events or issues from adequate productive causes into which they may be refunded—is vaguely accepted in the *Essay* as a fact of rational consciousness; but no explanation is given of its origin, only of the circumstances in which it arises in the individual mind. The inquisitive reader still asks why the individual mind is obliged to think back all changes into sufficient causes of which they are the issues, and why each set of antecedent phenomena, into which we thus refund new phenomena, themselves occasion a fresh intellectual demand for a preceding cause, while, after all, the mind is still left dissatisfied until it rests in a truly originaive or unconditioned cause. And yet if the intellectual need for a phenomenal cause were withdrawn there could be no rationality in, and therefore no reasoning possible about, Nature; for all the physical government of the universe depends upon it; and again, if uncaused or unconditioned power were withdrawn there could be no moral responsibility or moral government. This sort of *reductio ad absurdum* of every merely empirical analysis of the causal thought into what is strictly observable was foreign to Locke. His aversion from mysticism may have made him pass slightly over the mystery of an experience that like ours is conditioned by relations of place, which lead to the unimaginable thought of Immensity, of succession, which lead to the unimaginable thought of Eternity, and of change, which lead to the unimaginable thoughts of Substance and Power.

Locke's book about our individual ideas or thoughts leads naturally to his Third Book, which is especially about those of them that are general and abstract, and their connexion with language. It is here that he describes "abstract ideas"; here also he illustrates the confusion apt to be produced in our thoughts by the imperfections of language.

But we must pass on to the Fourth Book, about knowledge, which closes the *Essay*. Knowledge, he says, is perception or discernment of relations among our thoughts; real knowledge is discernment of their relations to what is objectively real. In his books about our "ideas" he had dealt with "simple apprehensions"; here he is concerned with "judgments" and "reasonings," and largely with judgments and reasonings about matters of fact. At the end of the long and patient research among our mere thoughts or simple apprehensions, he supposes his reader apt to complain that he has been "all this while only building a castle in the air," and to ask what the purpose is of all this stir about our thoughts, or our knowledge either, if we are not thereby carried beyond our own individual thoughts, and must accordingly regard our own fancies as the universe. "If it be true that knowledge lies only in the agreement or disagreement of our own ideas, the visions of an enthusiast and the reasonings of a sober man will be equally certain. It is no matter how things themselves are" (iv. 4, § 1). This is the keynote of the fourth book. It does not, however, carry him into an analysis of the rational constitution of knowledge as knowledge, as it would carry a transcendentalist of the 19th century, or even an associative philosopher. Transcendental analysis is too remote from human affairs to interest Locke. Hume, moreover, had not yet shown the difficulties which sceptical ingenuity could suggest against those facts of rational consciousness which Locke accepted without analysis. The sceptic who doubted the very constitution of reason and experience, because it could not be supported by external proof, was less in his view than minds blindly resting on authority or on irrational instincts. Universal scepticism like Hume's he would at any rate probably have regarded as a frivolous amusement, into which no human mind could permanently subside, and therefore unworthy of the serious attention of a wise man. What he wanted was to awaken a conscious conviction of principles apt to be dormant in the individual, but to which he believed a response must be given when reflexion was called forth. He was careless as to how far these principles might be developed into a reasoned system of speculative philosophy. "Where we perceive the agreement or disagreement of any of our ideas there is certain knowledge; and wherever we are sure these ideas agree with the reality of things, there is certain real knowledge" (chap. 4, § 18). He is anxious throughout to show that a great deal of commonly supposed real

knowledge is not entitled to be called "knowledge," and that it is merely presumption more or less probable. Instead of the immediate or the demonstrable insight, which alone is what he intends by knowledge, it is only "assent," "opinion," "probability."

Locke's report about human knowledge and the narrow extent of it is contained in the first thirteen chapters of the fourth book. The remainder of the book is concerned for the most part with what he found when he examined instances of "assent" or reasonable presumption, so liable to error, but on which human life really turns, as he and Butler are fond of reminding all transcendentalists. He takes for granted that "all the knowledge we have or are capable of" must be discernment of one or other of four sorts of agreement or disagreement among our thoughts themselves, or between our individual thoughts and the reality that is independent of them. All that can be cohesively known must be either (a) relations of identity and difference in what we are conscious of, that, for instance, "blue is not yellow"; or (b) that thought being mathematically related to that, as, for instance, that "two triangles upon equal bases between two parallels must be equal"; or (c) that one quality does or does not coexist with another in the same substance, as that "iron is susceptible of magnetic impressions"; or (d) that a thought has a real objective existence, independent of our individual mind, as that "God exists," or the "earth exists." What would now be called merely analytical knowledge exemplifies the first sort; mathematical (Locke would add moral) knowledge represents the second; physical and natural science, if this can become knowledge proper at all, would come under the third head; metaphysical knowledge forms the fourth. The third and several following chapters of this concluding book of the *Essay* are really an inquiry, under these four heads, how far knowledge is possible for man in mathematics, and in morality; about nature or natural phenomena in relations of coexistence and succession; and about the hyperphenomenal reality of our own existence, the existence of God, and the existence of matter.

Locke found a difference among the examples of what "knowledge" is that were offered in his natural experience. In some instances the known relation was at once evident, as when he judged that a circle was not a triangle, or three more than two and equal to one and two. In other cases the known relation was perceived only through the medium of something else, as in a mathematical conclusion, in which each step is taken by a rational intuition. The former is rationally intuited and the latter rationally demonstrated knowledge. In strictness all knowledge or rational certainty, he would have it, is in one or other of these two kinds. There is, however, a third sort of certainty which rather puzzled him. He found that "our perceptions of the particular existence of finite beings without us" go beyond mere probability, although they are not examples of rational necessity. There is nothing contradictory to reason in the supposition that our sense-perceptions are illusory, although we are, in fact, incapable of doubting their reality. We find ourselves "inwardly conscious of a different sort of perception," when we look on the sun by day and only imagine the sun at night. This, which is Locke's third sort of knowledge, might be called sense-perception. The difficulty that a "sense-perception" only of the present moment divorced from the past and the future, can be other than "blind," or irrational, does not occur to him.

Locke next inquired to what extent a human knowledge—in the way either of intuitive or demonstrative rationality, or of sense perception—is possible in regard to each of the four (already mentioned) sorts of knowable relation in which must be contained all knowledge we can be supposed capable of. Our knowledge must of course be confined within our "ideas"; for it is self-evident that we cannot have knowledge of a thing if consciousness is dormant. But there is only one of the four sorts of knowable relation in regard to which our knowledge is coextensive with our thoughts. The only knowable relation which he finds to be coextensive with his thoughts is that of "identity and diversity"; we cannot be conscious at all without distinguishing, and every affirmation implies negation. The second sort of knowable relation—purely rational concatenation among our thoughts—is intuitively and also demonstrably discernible in thoughts about quantities, in forms of space, time, and number; it is through this discernment that the mathematical sciences are constructed. Morality too, Locke thinks, as well as quantity, is capable of being thus rationalized. "Where there is no property there is no injustice," he offers as an example of a proposition "as certain as any demonstration in Euclid." Only we are more apt to be biased, and thus to have reason withdrawn from us, in dealing with problems of morality than in dealing with those of mathematics. Mankind might in consequence, in questions of morals, "with Egyptian darkness expect . . . ptian bondage, were not the candle of the Lord set up by him in their minds" (ch. 4, § 20). It is not easy to say whether the mathematics and morality which Locke finds thus demonstrable would be, as understood by him, sciences of what Kantists call analytical judgments founded on arbitrary definitions, or sciences consisting of synthetical judgments *a priori*.

In turning from mathematical and moral relations to those of

coexistence, and succession among phenomena,—Locke's third sort of knowable relation,—he finds the light of pure reason disappear, although the relations in question are those in which "the greatest and most important part of what we desire to know" consists. Of relations of this third kind, with which all the physical and natural sciences are concerned, he reports that "our knowledge is very short, if indeed we have any at all," and are not wholly thrown on presumptions of greater or less probability, or even left in ignorance. According to the philosophy of the *Essay* "there can be no science of bodies." All physical and natural science depends on a knowledge of the relations between the secondary qualities and other powers of bodies on the one hand, and the primary or mathematical qualities of their atoms on the other, or else "on something yet more remote from our comprehension." Now, as a rational insight of these relations, either intuitively or through demonstration, is beyond our reach, we must be satisfied with inductive presumptions, which the completest "verification" leaves, after all, only presumptions that more facts might prove to be unwarranted. Our inductive generalizations about particular things must always involve an element of possible error, or at least inadequacy, and therefore of probability only. Arbitrariness of connexion, and not rational necessity, reigns over the whole realm of physical government, with its relations of constant coexistence and succession; we only presume, as reasonably as we can, what its actually established laws are, and we can only presume that these laws are sustained in a steady and uniform government. The presumption is "sufficient for our purposes."

The amount of our knowledge under Locke's fourth category of knowable relations—those of real metaphysical or metaphenomenal existence—is reduced, in his report, to (a) rational perception of our own individual existence as conscious persons; (b) the demonstrable rationality of the existence of God or Supreme Mind; and (c) sense-perception of the existence of particular objects as long as, but only as long as, they are actually present in sense. That each individual person exists is manifested to himself in memory and no certainty beyond that of each passing thought while it passes can be greater than this. "If I doubt all other things," says Locke, after Descartes, "that very doubt makes me perceive my own existence, and will not suffer me to doubt of that" (iv. 9, 3). The eternal existence of God or Supreme Reason is with Locke only another way of expressing the principle of causality and sufficient reason in its universality, as suggested by our conviction that our own personal existence had a beginning. Each individual person knows that he now exists, and is convinced that he once had a beginning; with not less intuitive certainty of reason he knows that "nothing can no more produce any real being than it can be equal to two right angles." The final rational conclusion is that there must be eternally "a most powerful and most knowing Being, in which, as the origin of all, must be contained all the perfections that can ever after exist," and out of which can come only what it has in itself, so that, as the adequate cause, it must involve mind. There is thus a rational necessity for Eternal Reason, or what we call God. He cautiously adds elsewhere, "Though I call the thinking faculty in me 'mind,' yet I cannot, because of that name, equal it in any thing to that infinite and incomprehensible Being which, for want of right and distinct conceptions, is called 'mind' also, or the eternal mind."

Turning from the metaphysics of religion to the metaphysics of matter, nearly but perhaps not quite all that one can affirm or deny about things external to us is, according to Locke, not knowledge but only presumptive trust. We have on the whole no knowledge of the real existence of anything other than our own individual existence, that of Universal Reason, and that of particular objects of sense—while, but only while, they are present to our senses. "When I see an external object at a distance, a man for instance, I cannot but be satisfied of his existence while I am looking at him. (Locke might have added that when one thus "sees a man" it is only his visible qualities that are perceived; for his other qualities are as little 'actual present sensations' as if he was out of the range of the senses altogether.) But when the man leaves me alone, I cannot be certain that he still exists. There is no necessary connexion between his existence a minute since (when he was present to my sense of sight) and his existence now (when he is absent from all my senses); by a thousand ways he may have ceased to be. I have not that certainty of his continued existence which we call knowledge; though the great likelihood of it puts it past doubt. But this is but probability and not knowledge" (chap. 11, § 9). Either a rationally intuitive or a rationally demonstrative science of Nature is thus, according to Locke, impossible. A conception of the co-existences and successions of phenomena which form the external world being essentially the natural expression of the Universal Mind, and therefore capable of being reasoned about by our individual minds, in our gradual scientific progress towards agreement between the objective thought in nature and our subjective thoughts, was too speculative and mystical for Locke. He prefers to urge the matter-of-fact consideration that all our interpretations

of nature can be only presumed probabilities—not purely rational certainties. For him the vast region of reality—beyond our immediate sense-perceptions, memory, and the demonstrably necessary causal connexion with Universal Mind—is either presumed probability, grounded on faith, or else it is within that veil which separates what is behind it from reasonable belief as well as from knowledge. And he even fails to explain how anything at all above the world of sense can be “known” in a sense-perception that is restricted to the transitory “actual present sensation” of each moment. No past events and no future events can be known in the strict meaning of “knowledge.” It is unreasonable to demand a knowledge of more than abstract propositions and present momentary experiences. For the rest, we can only gradually convert beliefs into certainties that are absolute for all practical purposes. Such is the outcome of the *Essay*.

We might expect to learn from Locke something as to the rationale of the probable presumptions by which, as supplementary to our limited knowledge of real existence, we pass beyond the narrow sphere within which that knowledge is confined, according to his report of it, and possess ourselves so far of the unperceived past, distant, and future, in our experimental reasonings. He does little to satisfy us here. The concluding chapters of the fourth book contain judicious advice for human beings, whose lives are passed in a world of probabilities and presumptions, for avoiding the consequent risks of error or misinterpretation in their reasonings about what they see, —with or without the help of syllogism, the function of which, as an organ of discovery, he criticizes in the seventeenth chapter. Nothing is done to connect “probable” interpretations of the contingent phenomena of existence with the rational relations involved in the knowable part of its constitution, with which the preceding chapters were occupied.

This subject was resumed by Hume, very much at the point where Locke left it. With a still humbler view of the possible extent of human knowledge than Locke's, Hume proposed as a subject “worthy of curiosity,” to inquire what is “the nature of that evidence which assures us of any real existence and matter of fact, beyond the present testimony of our senses and the records of our memory,” remarking that “this part of philosophy has been little cultivated either by the ancients or the moderns.” The result of the inquiry was his announcement that Custom and the associative tendencies are a sufficient practical explanation of the formation of our experience. All beyond each present transitory “impression” is connected with it, through “ideas,” by means of Custom and Association. Hume's solvent, in the form either of individual or of inherited associative tendency, has since been made the philosophical explanation of all human experience in the Empirical Philosophy to which his *Inquiry* conducted. As for Locke, the “association of ideas”—either in the individual or as inherited—was not alluded to in the first edition of the *Essay*. The short chapter on the subject—now found at the end of the second book—was introduced in the second edition, not as in any way philosophically explanatory either of the thoughts or of the knowledge and probable beliefs of men, but as the chief source of human prejudices—as a cause of human errors against which men, dependent largely on probable presumptions, need in an especial manner to be warned. This useful chapter was an afterthought *added*, regarding a tendency which Locke saw was apt to spoil the “quality” of our individual thoughts, —apt, if one may put it so, to make them inconsistent with the Universal Thought latent in nature, by which our personal thoughts about what the laws in nature are must be tested.

On the other hand, an analysis like Kant's of what is abstractly implied in knowledge is even more foreign to the design of Locke, and to the tone of his philosophy, than the attempts of 18th and 19th century associationists and evolutionists to account for knowledge as if it were a fact of physical science. To show, in the case of any self-evident conception or judgment, that without it knowledge could not exist at all, would be to show what Locke took for granted, for all the purposes he had in view. His aim was to determine to what extent experience, presumed to be rationally constituted, could come within the individual consciousness of man. On the one hand, to analyse in the abstract the rational constitution of knowledge, into which he found that man is able only very partially to subdue the universe; or, on the other hand, to seek to the physical causes of its (partial) realization in the human mind;—both, were neither of them inquiries properly included in his enterprise.

Locke's function was to present to the philosophical mind of the modern world, in his own “historical plain method,” the largest assortment ever made by any individual of the actual facts of sense consciousness and rational consciousness in man. The further investigation of these facts, in Germany on the Transcendental Method, in England and France on the Empirical Method, as well as, by Butler and Reid, in Locke's own Common Sense Method—all under the stimulus of Hume's sceptical analysis—has employed philosophers since the *Essay on Human Understanding* collected materials for speculation.

*Literature.*—The *Essay concerning Human Understanding*, which was thus the philosophy of Locke's own life, and also of the century which followed, has passed through more editions than any similar book of ancient or modern times. Before the middle of the 18th century it had reached a thirteenth, and it has now passed through some fifty editions, besides being translated into Latin, French, Dutch, German, and modern Greek, in various versions. There are also several abridgments, in which the attempt is made to remove some of its innumerable repetitions. A considerable philosophical library might be turned out of the criticisms and comments to which it has given rise in the last hundred and ninety years. In addition to those which appeared when Locke was alive, some of which are mentioned above, among the most important are Leibnitz's *Nouveaux Essais sur l'Entendement Humain*—written about 1700 and published in 1765, in which each chapter of the *Essay* of Locke is examined in a corresponding chapter; Cousin's *École Sensualiste: Système de Locke*, in his *Histoire de la Philosophie au XVIII. Siècle*, 1829; and the recent criticisms in Professor Green's Introduction to the *Philosophical Works of Hume*, 1874. The *Letters on Toleration, Thoughts on Education, and Reasonableness of Christianity* have also gone through many editions, and been translated into different languages. The first collected edition of Locke's Works was in 1714, in three folio volumes. The best edition is that by Bishop Law, in four quartos, 1777. The one most commonly known is in ten volumes, 1812. The *Essay*, as well as the other treatises, needs textual revision and critical annotation.

The *Loops of Le Clerc* (*Bibliothèque Choisie*, 1705) has been the basis of the memoirs of Locke prefixed to the successive editions of his Works, and contained in the biographical dictionaries. In 1830 a *Life of Locke*, in two volumes, was published by his descendant Lord King. This adds a good deal to what was previously known, as Lord King was able to draw from the mass of correspondence, journals, and commonplace books of Locke in his possession. In the same year Dr Thomas Foster published some interesting letters from Locke to Benjamin Furley. The most copious account of the details of Locke's life is contained in the two volumes by Mr Fox Bourne (1876), which are the results of laborious and faithful research in the Shutebury Papers, Locke MSS, in the British Museum, the Public Record Office, the Lambeth, Christ Church, and Bodleian libraries, and in the Remonstrants' library at Amsterdam. (A. C. F.)

LOCKHART, JOHN GIBSON (1794-1854), was born in the manse of Cambusnethan in Lanarkshire, where his father, Dr Lockhart, was minister. His mother was daughter of the Rev. John Gibson, minister of St Cuthbert's, Edinburgh. In 1796 his father was transferred to Glasgow, where John Lockhart was reared and educated. He derived his rare abilities from his mother, and his first regular teaching from the High School of Glasgow. He appears to have been from the first distinguished as a clever, but by no means industrious boy. Like most clever boys he read everything that came in his way; and what he had once devoured he never forgot; for his memory was so retentive that, in after life, like Macaulay and Sir George Lewis, he seldom found it necessary to verify a passage for quotation. No livelier boy than John Lockhart ever lived; in or out of school his sense of fun and humour, expressed in joke, sarcasm, and pencil caricatures, was irrepressible. At the same time, however merry and mischievous, he was a proud and reserved boy; and this was the side he mostly turned to the outer world as a man. The struggle between a very affectionate nature and a determination not to show his feelings, or perhaps an incapacity to give way to them, cost him dear. A younger brother and sister were carried off within a few days of each other. John appeared to bear the loss like a stoic, but he fell seriously ill, and had to be removed finally from the High School. On his recovery, though still under twelve years of age, he was entered at college, where he sketched the professor for the amusement of his companions, as he had sketched the masters before. When examination time came, he astonished all by a display of erudition, especially in Greek authors, of the acquisition of which he had given no signs; a Snell exhibition, just vacant at Oxford, was accordingly offered to him and accepted.

Lockhart was not turned fourteen when he was entered at Balliol College, but he soon asserted his character and his powers. His fun, and satire made him at once popular and formidable, while beyond the regular studies of the place he acquired a great store of extra knowledge. He read French, Italian, German, and Spanish, was curious in classical and British antiquities, and well versed in heraldic and genealogical lore. Lockhart went up to the schools in the Eastern term of 1813—not nineteen years of age—and, notwithstanding the most audacious employment of part of his time in caricaturing the examiners, he came out first in classics. The name of Henry Hart Milman, a subsequent friend through life, stood next his. For mathematics he never had the least inclination.

He now quitted Oxford, and before settling to the study of Scottish law, for which his father had designed him, he indulged a long cherished wish to visit Germany. His knowledge of German had introduced him to the great band of poets and scholars who had suddenly exalted the fame of German literature. Lockhart had no means to undertake the journey; but here his reputation came to his aid. A proposal to translate Frederick Schlegel's *Lectures on the Study of History* was accepted by Mr Blackwood, and the price of the labour paid before a line was written. Lockhart always spoke of this as a most generous act on "Ebony's" part, and his friendship with the liberal publisher lasted through life. He meanwhile paid his visit to Germany, was introduced to Goethe at Weimar, traversed France and the Netherlands, made careful observations on pictures and architecture, and returned to Edinburgh to study law by the time he was twenty-one. In 1816 he was called to the bar. But he had no friends among writers and attorneys, his brilliant powers of conversation did not comprise that of public speaking, and few, if any, briefs came in. His habits of observation, however, turned the time to a use afterwards exemplified in *Peter's Letters*.

Edinburgh was then the stronghold of the Whig party. The *Edinburgh Review* was their organ, and it was not till 1817 that the Scotch Tories found a national channel of assertion and defence—namely, in *Blackwood's Magazine*. This periodical held its way dully enough with its first numbers, when suddenly an outburst of wit and ridicule directed against the hitherto unchallenged writers of the Whig party, surpassing them in cleverness and equalling them in personalities, electrified the Edinburgh world. Wilson (Christopher North), Hogg (the Ettrick Shepherd), and Lockhart had joined the staff, and retaliation for long pent-up wrongs began. Lockhart's pen contributed scholarly papers on various subjects, including hearty criticism and eulogium on Coleridge, Wordsworth, and other victims of a *Review* which could find only scant praise even for Walter Scott. His translations also of the Spanish ballads appeared for the greater part in *Blackwood*. But his pen was more often dipped in caustic, dealing out attacks and recriminations which led to regrettable consequences. Meanwhile the gifted and handsome young man, for Lockhart's head was cast in the highest type of brilliant manly beauty, had attracted the notice of Walter Scott. They met first in 1818. The acquaintance soon ripened into friendship, and that friendship led to the union between Lockhart and Scott's eldest daughter, Sophia, in April 1820. For more than five years after his marriage Lockhart tasted the best form of domestic happiness. Winters spent in Edinburgh and summers at a cottage fitted up for them at pretty Chiefswood, near Abbotsford, gave the young couple the constant enjoyment of friendship, society, and even worldly distinction, added to the blessing of a perfect home. At Chiefswood Lockhart's two eldest children, John Hugh and Charlotte, were born; Walter, later, at Brighton.

Between 1818, when he joined the *Blackwood* staff, and 1825 Lockhart's pen was indefatigably at work. As early as 1819 *Peter's Letters to his Kinsfolk* appeared. Like Goldsmith's *Citizen of the World*, these profess to give the impressions of a stranger in a new country. Dr Peter Morris, a Welsh physician, passes some time in Scotland, especially in Edinburgh, and describes the men and manners very freely to his relations at home. His descriptions of the chief notabilities of the day have a certain historical, almost antiquarian interest, though now the least interesting part of the work. What we enjoy most is the reflexion of a young and ardent mind dealing out opinions and estimates far beyond its years, the cor-

rectness of which time has singularly verified. The amount of reading too which crops out in every page is amazing; a perpetual play of allusions, quotations, and happy nicknames—for which Lockhart to his last days was famous—is given with a richness of tone of which the reader might tire, but for the simple, vigorous English in which it is clad. A chapter on dandies is a *chef d'œuvre* in its way. That a work describing the appearance and idiosyncrasies of many living individuals should give offence was a matter of course. His description of the northern universities was not likely to please; while for the unsparing ridicule and ruthless quizzing heaped on the General Assembly—"men," he is supposed to have said, "of like passions with our-elves, but worse manners"—it would be strange indeed if the author had escaped with impunity.

*Valerius, a Roman Story*, followed next (1821). As *Valerius* was intended to illustrate the manners and customs of Rome in the time of Trajan, so *Reginald Dalton*, published in 1823, aimed at exhibiting the life of an undergraduate at Oxford as he had known it. Lockhart's strength did not lie in novel writing, and, to those who read *Reginald Dalton* now, the digressions of the author are far more interesting than the adventures of the hero. But a plot of simpler construction and intense passion showed Lockhart's strength to greater advantage. *Adam Blair* (1822) is a tale of temptation, fall, and repentance, each fearful in its way, told with tremendous power, and as far removed from all that is morbid and false in sentiment as the author was himself. It gave great offence to the Scottish Church, for the erring man is a minister, and the scene is laid in a Scottish manse.

In 1826, on the death of Mr Gifford, the editorship of the *Quarterly Review* was offered to Lockhart, and accepted. He was singularly free in position, however far from idle. He was next heir to Milton Lockhart, the property of his unmarried half-brother, who eventually survived him: the legal profession to which he had been destined was virtually abandoned; and time had shown him that the party strife which prevailed in Edinburgh was demoralizing to both sides. This last conviction did the most to reconcile him to the separation from all Scottish surroundings. His friends gave him a farewell dinner, when, labouring with strong feelings, and with his habitual dislike or incapacity to express them, he said, on returning thanks, "You all know that I am no speaker; had I been, there would have been no occasion for this parting."

The conduct of a great periodical like the *Quarterly Review* is the touchstone of a man's capacity, knowledge, and temper. Looking back to an editorship which lasted twenty-eight years, it must be admitted that Lockhart maintained a high position in all these respects. He contributed largely to the *Review* himself, his biographical articles being especially admirable. He also found time, being a very glutton in work, for many a paper in *Blackwood*; he wrote what remains the most charming of the biographies of Burns; and he undertook the superintendence of the series called *Murray's Family Library*, which he opened in 1829 with a *Life of Napoleon*. But his chief work was the *Life of Walter Scott*, a task at once of love and duty. Lockhart knew the great and good man as no one else did, and felt that, whatever the mistakes in judgment, no life from first to last could better afford complete revelation. There have not been wanting those in Scotland who have taxed him with ungenerous exposure of his subject, but to most healthy minds the impression conveyed by the biography was, and is, one of the most opposite kind—namely, that Lockhart has almost deified Scott. The labour incurred was in so far one of love, inasmuch as the writer reaped

no part of its considerable proceeds, but resigned them absolutely for the benefit of Scott's creditors.

Lockhart's life in London was a long succession of constant work, of dignified social success, and of heavy bereavements. His eldest boy, the suffering "Hugh Littlejohn" of the *Tales of a Grandfather*, died in 1831. Sir Walter died in 1832; Anne Scott, the second daughter, who had come to live with the Lockharts in London, in 1833; Mrs Lockhart in 1837. The love for his children was for long the one bright element in his life. But the death in 1852, and, sadder still, the previous life, of his surviving son Walter, a fine youth, who had entered the army under unfortunate auspices, broke down all that remained of health and spirit in the father.

Failing health compelled Lockhart to resign the editorship of the *Quarterly Review* in 1853. He spent the next winter in Rome, but returned to England with no restoration of vital power. He was conveyed to Abbotsford, where, under the tender care of his daughter Mrs Hope Scott, and cheered by the prattle of his granddaughter, now the possessor of Abbotsford, he lingered till his death, November 25, 1854. He was buried in Dryburgh Abbey, at the feet of Walter Scott. (E. E.)

LOCKPORT, capital of Niagara county, New York, about 21 miles east of Niagara Falls, at the point where the New York Central Railroad crosses the Erie canal. It takes its name from the locks (ten in number) by which the canal is lowered 66 feet from the level of Lake Erie to that of the Genesee river; and its prosperity as a manufacturing centre is due to the water-power. The surrounding country is a rich agricultural district, and in the vicinity are extensive limestone and sandstone quarries. Flour-mills are prominent among the industrial establishments; there are also numerous saw-mills, cotton and woollen factories, foundries, &c. Lockport was made a city in 1865. The population in 1870 was 12,426; in 1880, 13,522. The buildings in the business part of the city are generally heated by steam on the Holly distributing system, which originated in Lockport, as did the celebrated Holly water-works system.

LOCLE, LE, a large town-like village of Switzerland, in the canton of Neuchâtel, 10 miles W.N.W. from Neuchâtel. Along with La Chaux de Fonds, 5 miles north-east, it is the seat of the most extensive watch-making industry in the world; and it also carries on the domestic manufacture of lace. The valley in which Le Locle is situated used to be subject to inundation, but in 1802-6 a tunnel was constructed by which the surplus waters of the Bied discharge into the Doubs. About a mile to the west of the town the stream plunges into a deep chasm, and on the almost vertical face of the rock are what are usually called the subterranean mills of Cul des Roches, situated one above the other, to turn the water-power to account. The population of the commune was 10,464 in 1880.

LOCRI, a people of Greece who are found in two different districts, on the Ægean coast opposite Eubœa and on the Corinthian Gulf between Phocis and Ætolia. The former are divided into the northern Locri Epicnemidii, so called from Mount Cnemis, and the southern Locri Opuntii, whose chief town was Opus; but the name Opuntii is applied to the whole district by Thucydides, Herodotus, &c. Homer knows no distinction of tribes among the Locri. They were considered by Aristotle to be a Lelegian tribe; but they became Hellenized at an early time, and rank in Homer along with the other Greek tribes before Troy. Their national hero is Ajax Oileus, who often appears on coins. The Locri Ozolæ on the Corinthian Gulf were a rude and barbarous race who make no appearance in Greek history till the Peloponnesian War. It is said that they separated from the eastern Locri four genera-

tions before the Trojan war, but Homer does not mention them. The most probable view is that the Locri were a single race spread from sea to sea, that subsequent migrations forced them into two separate districts, that the eastern Locri advanced with the growth of civilization, while the remote Ozolæ remained ignorant and barbarous.

A colony of Locrians, probably Opuntians, though Strabo expressly calls them Ozolæ, settled at the south-west extremity of Italy about the end of the 8th century B.C. They are often called Locri Epizephyrii from the promontory Zephyrion 15 miles south of the city. The earliest and most famous event recorded in the history of the Italian Locri is the legislation of Zaleucus about the middle of the 8th century B.C. The Locri boasted that Zaleucus was the first of the Greeks to promulgate a written code of laws. A body of laws under his name existed in the city throughout the historical period, but the name of Zaleucus is almost as much surrounded with legend as that of Lycurgus. The Locrians are said to have defeated the people of Crotona in a great battle at the Sagra, perhaps some time in the 6th century B.C., and in this flourishing period they founded colonies along the south coast of the peninsula. Their nearest neighbour was Rhegium, and the continual wars that raged between the two cities often drew other states into their quarrels. They sent ships to aid Sparta in the Lacedæmonian war. They were allied with the elder Dionysius of Syracuse, who gave them great accessions of territory (389-88 B.C.); the younger Dionysius ruled them as tyrant (356 B.C.). They admitted a Roman garrison before the expedition of Pyrrhus, but sided against the Romans with him and with Hannibal (216 B.C.). The town was finally captured by Scipio (205 B.C.). From this time we hear little of Locri. It seems still to have existed in the 6th century A.D., but in the Middle Ages it had disappeared entirely. The site and remains have been described by the Duc de Luynes (*Ann. Inst. Arch.*, ii.). It possessed a famous temple of Proserpine. The town is celebrated by Pindar, *Ol.* x. and xi.

LOCUS, in Greek τόπος, a geometrical term, the invention of the notion of which is attributed to Plato. It occurs in such statements as these:—the locus of the points which are at the same distance from a fixed point, or of a point which moves so as to be always at the same distance from a fixed point, is a circle; conversely a circle is the locus of the points at the same distance from a fixed point, or of a point moving so as to be always at the same distance from a fixed point; and so in general a curve of any given kind is the locus of the points which satisfy, or of a point moving so as always to satisfy, a given condition. The theory of loci is thus identical with that of curves; and it is in fact in this very point of view that a curve is considered in the article CURVE; see that article, and also GEOMETRY (ANALYTICAL). It is only necessary to add that the notion of a locus is useful as regards determinate problems or theorems; thus, to find the centre of the circle circumscribed about a given triangle ABC, we see that the circumscribed circle must pass through the two vertices A, B, and the locus of the centres of the circles which pass through these two points is the line at right angles to the side AB at its mid-point; similarly the circumscribed circle must pass through A, C, and the locus of the centres of the circles through these two points is the line at right angles to the side AC at its mid-point; thus we get the ordinary construction, and also the theorem that the lines at right angles to the sides, at their mid-points respectively, meet in a point. The notion of a locus applies, of course, not only to plane but also to solid geometry. Here the locus of the points

single (or onefold) condition is a surface; the locus of the points satisfying two conditions (or a twofold condition) is a curve in space, which is in general a twisted curve or curve of double curvature.

**LOCUST.** In its general acceptance this term is strictly applicable only to certain insects of the order *Orthoptera*, family *Acrydidae* (see *INSECTS*); and it is advisable to reiterate that according to modern classification the family *Locustidae* is now viewed in a sense that does not admit of what are popularly termed "locusts" being included therein. We universally associate with the term the idea of a very destructive insect; therefore many orthopterous species that cannot be considered true locusts have had the term applied to them; in North America it has even embraced certain *Hemiptera-Homoptera*, belonging to the *Cicadidae*, and in some parts of England cockchafers are so designated. In a more narrow definition of the term we are wont to associate with the destructive propensities the attribute of migration, and it therefore becomes necessary that a true locust should be a migratory species of the family *Acrydidae*. Moreover, the term has yet a slightly different signification as viewed from the Old or New World. In Europe by a locust is meant an insect of large size, the smaller allied species being ordinarily known as "grasshoppers," hence the notorious "Rocky Mountain locust" of North America is to Eastern ideas rather a grasshopper than a locust.

In Europe, and a greater part of the Old World, the best known migratory locust is that which is scientifically termed *Pachytylus migratorius*, to which is attached an allied (but apparently distinct) species known as *P. cinerascens*. Another locust found in Europe and neighbouring districts is *Caloptenus italicus*, and still another, *Acrydium peregrinum*, has once or twice occurred in Europe (even in England in 1869), though it can only be considered a straggler, its home (even in a migratory sense) being more properly Africa and Asia. These practically include all the locusts of the Old World, though a migratory species of South Africa known as *Pachytylus pardalinus* (presumed to be distinct from *P. migratorius*) should be mentioned. The Rocky Mountain locust of North America is *Caloptenus spretus*, and in that continent there occurs an *Acrydium* (*A. americanum*) so closely allied to *A. peregrinum* as to be scarcely distinct therefrom, though there it does not manifest migratory tendencies. In the West Indies and Central America the absolutely true *A. peregrinum* is also reported to occur.

As to general biology, a few words will suffice. The females excavate holes in the earth in which the eggs are deposited regularly arranged in a long cylindrical mass enveloped in a glutinous secretion. The young larvae hatch, and immediately commence their destructive career. As these insects are "hemimetabolic" (see *INSECTS*), there is no quiescent stage; they go on increasing rapidly in size, and as they approach the perfect state the rudiments of the wings begin to appear. Naturally in this stage they are incapable of flight, but their locomotive powers are nevertheless otherwise extensive, and their capacity for mischief very considerable, for their voracity is great. Once winged and perfect these powers become infinitely more disastrous, redoubled by the development of the migratory instinct. The laws regulating this instinct are not yet perfectly understood. Food and temperature have a great deal to do with it, and there is a tendency for the flights to take a particular direction, varied by the physical circumstances of the breeding districts. So likewise it is certain that each species has its area of constant location in which it always exists, and its area of extraordinary migration to the extremes of which it only occasionally extends. Perhaps the most feasible of the suggestions as to the causes

of the migratory impulse is that locusts naturally breed in dry sandy districts in which food is scarce, and are thus impelled to wander in order to procure the necessities of life; but against this it has been argued that swarms bred in a highly productive district in which they have temporarily settled will seek the barren home of their ancestors. Another ingenious suggestion is that migration is intimately connected with a dry condition of the atmosphere, urging them to move on until compelled to stop for food or procreative purposes. The distance particular swarms may travel depends upon a variety of circumstances, such as the strength of impulse, the quantity of food, and many other causes. Certain it is that 1000 miles may, in particular cases, be taken as a moderate estimate; probably it is often very much less, certainly sometimes very much more. As a rule the progress is only gradual, and this adds vastly to the devastating effects, which may be likened to those caused by a foreign army levying black mail upon the inhabitants of an invaded country through which it is marching. When an extensive swarm temporarily settles in a district, all vegetation rapidly disappears, and then hunger urges them on another stage. Such is their voracity that it has been tolerably well ascertained that the large Old World species, although undoubtedly phytophagous, are often compelled by hunger to attack at least dry animal substances, and even cannibalism has been asserted as an outcome of the failure of all other kinds of food. The length of a single flight must depend upon circumstances. From certain individual peculiarities in the examples of *Acrydium peregrinum* that were taken in England in 1869, it has been asserted that they must of necessity have come direct by sea from the west coast of Africa; and what is probably the same species has been seen in the Atlantic at least 1200 miles from land, in swarms completely covering the ship, and obscuring the air; thus, although it is no doubt usual for the swarms to rest during the night, it undoubtedly happens in certain cases that flight must be sustained for several days and nights together. The height at which swarms fly, when their horizontal course is not liable to be altered by mountains, has been very variously estimated at from 40 to 200 feet, or even in a particular case to 500 feet. A "dropping from the clouds" is a common expression used by observers when describing the apparition of a swarm. The extent of swarms, and the number of individuals in a swarm, are matters that must of necessity be purely speculative. That the sun may sometimes be utterly obscured, and the noise made by the rustling of the wings be deafening, is confirmed by a multitude of observers. We prefer to decline the attempt to grapple with so vast a subject,—not unnaturally so when one observer says of a particular swarm that, when driven out to sea and drowned, the dead bodies washed up formed a bank 50 miles long and 3 or 4 feet high.

No special periodicity appears to have governed these flights (which, it is necessary to state, happily do not occur to an alarming extent every year), still an American writer (Mr Thomas) makes the interesting remark that the interim between the years of superlatively extraordinary appearance is both in Europe and America "very nearly a multiple of 11."

In Europe the best known and ordinarily most destructive species is *Pachytylus migratorius* (fig. 1), and it is to it that the numerous records of devastations in Europe mainly refer, but it is probably not less destructive in many parts of Africa and Asia. Eastern Europe, and especially the plains of southern Russia, appear to be more especially liable to its attacks. That the arid steppes of Central Asia are the home of this insect appears probable; still much on this point is enveloped in uncertainty. In any case the area of permanent distribution, according to Köppen (who published an elaborate memoir on the subject in 1871), is enormous, and that of occasional distribution is still greater. The former area extends from the parallel of 40° N. in Portugal, rising to 48° in France and Switzerland, and

passing into Russia at 55°, thence continuing across the middle of Siberia, north of China to Japan; thence south to the Fiji Islands, to New Zealand, and North Australia; thence again to Mauritius and over all Africa to Madeira. But Koppen remarks that the southern distribution is uncertain and obscure. Taking exceptional distribution, it is well known that it occasionally appears in the British Isles, and has in them apparently been noticed as far north as Edinburgh; so also does it occasionally appear in Scandinavia, and it has probably been seen up to 63° N. in Finland. Looking at this vast area, it is easy to conceive that an element of uncertainty must always exist with regard to the exact determination of the species, and in Europe especially is this the case, because (as before stated) there exists an apparently distinct species, known as *P. cinereus*, which Koppen does not take into

"locust." In the Argentine Republic a (possibly) distinct species (*A. paranense*) is the migratory locust.

*Caloptenus italicus* (fig. 3) is a smaller insect, with a less extended area of migration; and, though from this cause its ravages are not so notable, still the destruction occasioned in the districts to which

FIG. 1.—*Pachytylus migratorius*. This and the other figures are all natural size.

account. This latter species is certainly the most common of the "locusts" occasionally found in the British Isles, and De Selys-Longchamps is of opinion that it breeds regularly in Belgium, whereas the true *P. migratorius* is only accidental in that country. In the case of this, as of all other locusts, it is impossible within the limits of this article to chronicle even the years of greatest abundance. That they are probably as destructive now as formerly appears within the bounds of belief. At any rate we read that only a year or two ago a detachment of Russian soldiers in Turcomania was so beset that a stampede at last took place, and eventually the men were held prisoners by the insects forty-eight hours until the villagers killed them and carried them away for manure, locomotion being as difficult as if the men had been on ice.

*Acrididae peregrina* (fig. 2) can scarcely be considered even an accidental visitor to Europe; yet it has been seen in the south of Spain, and, most extraordinarily, in many examples spread over a large part of England in the year 1869. It is a larger insect than *P. migratorius*. No serious attempt to define the range of this species has yet been made, but there is every reason to believe that it is the most destructive locust throughout Africa and India and other parts of tropical Asia, and its ravages are not one whit less important than are those of *P. migratorius*. Presumably it is the species that, on more than one occasion, has been noticed in a vast swarm in the Atlantic, very far from land, and presumably also it occurs in the West Indies and some parts of Central America. But it has been already remarked that *A. americanum* of North America, although so closely allied as to be scarcely distinguishable, is said not to be migratory, and is therefore scarcely a true

FIG. 2.—*Acridium peregrinum*.

it is limited is often scarce less than that of its more terrible allies. It is essentially a species of the Mediterranean district, and especially of the European side of that sea, yet it is also found in North Africa, and appears to extend far into southern Russia.

FIG. 3.—*Caloptenus italicus*.

*Caloptenus spretus* (fig. 4) is the "Rocky Mountain locust" or "hateful grasshopper" of the North American continent. Though a comparatively small insect, not so large as some of the grasshoppers of English fields, its destructiveness has procured for it within the last twenty years a notoriety scarcely excelled by that of any other. It is only recently that the persistent migration of American settlers westward extended into the home of this creature. Travellers and prospectors in these regions had previously spoken of enormous swarms of a destructive grasshopper as existing there, and no doubt these occasionally extended into regions already civilized, but the species was not recognized as distinct from some of its non-migratory congeners to which it is so closely allied as to require a practised entomological eye to separate it therefrom. As time drew on, the various "State entomologists" made it their special duty to report on the insect, and at length, in 1877, the matter had become so serious that Congress appointed a United

States Entomological Commission to investigate the subject, and report upon the best (if any) means of counteracting the evil effects of the pest. The result, so far as published, consists of two enormous volumes, teeming with information, and taking up the whole subject of locusts both in America and the Old World. *C. spretus* has its home or permanent area in the arid plains of the central region east of the Rocky Mountains, extending slightly into the southern portion of British North America; outside this

FIG. 4.—Rocky Mountain Locust (*Caloptenus spretus*). *a, a, a*, female in different positions, ovipositing; *b*, egg-pod extracted from ground, with the end broken open; *c*, a few eggs lying loose on the ground; *d*, *e* show the earth partially removed, to illustrate an egg-mass already in place, and one being placed; *f* shows where such a mass has been covered up. (After Riley.)

is a wide fringe to which the term sub-permanent is applied, and this is again bounded by the limits of only occasional distribution, the whole occupying a large portion of the North American continent; but it is not known to have crossed the Rocky Mountains westward, or to have extended into the eastern States.

As to remedial or preventive measures tending to check the ravages of locusts, little unfortunately can be said, but anything that will apply to one species may be used with practically all. One point is certain; direct remedies must always be of small avail. Something can be done (as is now done in Cyprus) by offering a price for all the egg-tubes collected, which is certainly the most direct manner of attacking them. Some little can be done by destroying the young larvæ while yet in an unwinged condition, and by digging trenches in the line of march into which they can fall and be drowned or otherwise put an end to. Infinitesimally little can be done with the winged hordes having the migratory instinct upon them; starvation, the outcome of their own work, probably here does much. It has been shown that with all migratory locusts the breeding places, or true homes, are comparatively barren districts (mostly elevated plateaus); hence the progress of civilization and colonization, with its concomitant necessity for converting those heretofore barren plains into areas of fertility, may (and probably will) gradually lessen the evil.

Locusts, like all other animals, have their natural enemies. Many birds greedily devour them, and it has many times been remarked that migratory swarms of the insects were closely followed by myriads of birds. Predatory insects of other orders also attack them, especially when they are in the unwinged condition. Moreover, like all other insects, they have still more deadly insect foes as parasites. Some attack the fully developed winged insect. But the greater part adopt the more insidious method of attacking the eggs. To such belong certain beetles, chiefly of the family *Cantharidae*, and especially certain two-winged flies of the family *Bombyliidae*. These latter, both in the Old and New World, must prevent vast quantities of eggs from producing larvæ. Popular ignorance on this subject is yet great, and within a few months before this article was written it was exemplified in a remarkable manner by a suggestion from the Government officials of Cyprus that a certain parasite known to be destructive to the eggs in Asia Minor might be introduced into the island, a suggestion immediately followed by the discovery that what is probably the same parasite already existed there.

A flight of locusts would appear not to be always an unmixed evil, even to man. The larger Old World species form articles of food with certain semi-civilized and savage races, by whom they are considered as delicacies, or as part of ordinary diet, according to the race and the method of preparation.

*Literature.*—Kirby and Spence, *Introduction to Entomology*, 7th ed., London, 1856; Kùppen, "Die geographische Verbreitung der Wanderheuschrecke," in *Geograph. Mittheilungen*, vol. xvi 1871; Goßwäcker, *Die Wanderheuschrecke*, Berlin, 1876; *Reports of the United States Entomological Commission on the Rocky Mountain Locust*, by Riley, Packard, Thomas, and others, 2 vols., Washington, 1878-80. (R. M. L.)

**LOCUST-TREE**, *Ceratonia Siliqua*, L., the carob-tree, of the tribe *Cassieæ* of the order *Leguminosæ*, is the sole species, widely diffused spontaneously and by cultivation from Spain to the eastern Mediterranean regions, and from Egypt to Bornou in Central Africa (Hogg, Hooker's *Journ. of Bot.*, i. 113), and imported to Hindustan (Graham, p. 254). It differs from all leguminous plants by the dilated disk to the calyx. It has no petals, and the flowers are polygamous or diceious. The legume is compressed, often curved, indehiscent, and coriaceous, but with sweet pulpy divisions between the seeds, which, as in other genera of the *Cassieæ*, are albuminous. The pods are eaten by men and animals, and in Sicily a spirit and a syrup are made from them. These husks being often used for swine are called swine's bread, and are probably referred to in the parable of the Prodigal Son. It is also called St John's bread, from a misunderstanding of Matt. iii. 4. The carob-tree was regarded by Sprengel as the tree with which Moses sweetened the bitter waters of Marah (Exod. xv. 25), as the *kharrûb*, according to Avicenna (p. 205), has the property of sweetening salt and bitter waters. Gerard (*Herball*, p. 1241) cultivated it in 1597, it having been introduced in 1570 (London's *Arb.*, ii. 660). For various names, extent of distribution, historical references, &c., see Pickering's *Chron. Hist. of Pl.*, p. 141.

**LODÈVE**, capital of an arrondissement of the department of Hérault, France, lies at an elevation of 674 feet, under a range of hills rising to 2790 feet, in a small valley where the Soulondré joins the Lergue, a tributary of the Hérault, 31 miles east-north-east from Montpellier. A bridge over the Lergue connects the town with the faubourg of Carnes on the left bank of the river, and two bridges over the Soulondré lead to the extensive ruins of the Château de Montbrun. There is railway communication with Agde by a line following the Hérault valley. The old cathedral of St Fulcran, founded by him in 950, was rebuilt in the 14th century and restored in the 16th; the cloister, dating from the 15th century, is ornate in style. In the picturesque environs of the town stands the well-preserved monastery of St Michel de Grammont, dating from the 12th century; it is now used as farm buildings. In the neighbourhood are three fine dolmens. Lodève is one of the most important industrial centres of the south of France, upwards of 7000 workmen being employed in the manufacture of woollens for army clothing; the aggregate horse-power of the factories is 1500. Wool is imported in large quantities from the neighbouring provinces, and from Morocco; the exports are cloth to Italy and the Levant, wine, brandy, chemicals, and wood. The population in 1876 was 10,528.

Luteva existed prior to the invasion of the Romans, who for some time called it *Forum Nervens*. The inhabitants were converted to Christianity by St Flour, first bishop of the city, about 323. After passing successively into the hands of the Visigoths, the Franks, the Ostrogoths, the Arabs, and the Carolingians, it became in the 9th century a separate countship, and afterwards the domain of the bishops of Lodève. During the religious wars it suffered much, especially in 1573, when it was sacked. It ceased to be an episcopal see in 1789.

**LODGE**, THOMAS (c. 1556-1625), dramatist, novelist, pamphleteer, poet, but not player, was born about the year 1556 at West Ham, and was possibly the son of a namesake, shortly afterwards lord mayor of London. He was educated at Trinity College, Oxford, and then entered as a student at Lincoln's Inn, where, as in the other Inns of Court, a love of letters, and a crop of debts and difficulties, alike grew as matters of course. Thus already as a young man he preferred the looser ways of life and the lighter aspects of literature. When the penitent Stephen Gosson had (in 1579) published his *Schools of Abuse*, Lodge took up the glove in his *Defence of Poetry, Music, and Stage*.

plays (1579 or 1580), which shows some of the moderation as well as of the learning befitting a scholar and a gentleman. The publication was, however, prohibited, besides being answered by Gosson in his *Plays Confuted in Five Actions*, as by a man sure of his ground if not of his cause. Having fleshed his pen, Lodge displayed a strong inclination for continuing its use. In 1584 he published his *Alarum Against Usurers*, a pamphlet to which he no doubt gave the benefit of his personal experience, and in which he mentions the fate of his previous literary venture. Soon after this his years of wandering seem to have begun. It is clear that their primary cause lay in the straits to which he had been reduced, or had reduced himself; that he ever took so bold a leap into disreputableness as to become an actor is improbable in itself, and the assertion which has been made to that effect has been shown to rest on something less satisfactory than conjecture. Lodge joined Captain Clarke in his raid upon Terceira and the Canaries, and seems, in 1591, to have made another similar voyage with Cavendish. During the former expedition, he, to beguile the tedium of his voyage, composed his prose tale of *Rosalynde, Euphues' Golden Legacie*, which, published in 1590, afterwards suggested the story of *As You Like It*. The novel, which in its turn owes some, though no very considerable, debt to the *Tale of Gamelyn*, is a pleasing example of the Euphuistic manner, but proves how slight an advance an individual author of secondary rank is able to effect in a branch of composition of which the genius of his age has not taken hold. In the year before (1589) Lodge had already given to the world a volume of poems, including the delectable *Scyllus Metamorphosis*. One would gladly resign this and much else of Lodge's sugared verse, together with some of his perfumed prose, for the lost *Sailor's Kalender*, in which he must after some fashion have told of his sea adventures. During the last decade of the century he produced a *farrago* of literary products—a Juvenal, if not a very "Young Juvenal," at least in the readiness of his wit and in the robustness of his moral indignation. In conjunction with Greene he produced, in a popular vein, the odd but far from feeble play of *A Looking Glasse for London and England*. Probably about the same time he wrote his *Tragedy of the Wounds of Civil War* lively set forth in the *True Tragedies of Marius and Sylla* (published 1594), a good second-rate piece in the fashion of its age, and deficient neither in rhetorical nor in comic vigour. His *Life and Death of William Longbeard* (1593), and his *History of Robin the Dives*, are among his contemporary non-dramatic works; to which should be added *Phyllis* (1593), a collection of lyrical pieces, and a *Fig for Momus* (on the strength of which he has been rather loosely termed the earliest English satirist). In his later years,—possibly about 1596, when he published his *Wits Miserie*, which is dated from Low Leyton, and the prose *Prosopopeia* (if, as seems probable, it was his), in which he repents him of his "lewd lines" of other days,—he was engaged in the practice of medicine, for which he is said to have qualified himself by a degree at Avignon. His works henceforth have a sober cast, comprising a translation of Josephus (1602) and another of Seneca (1614), besides a *Treatise of the Plague* (1603), and a popular manual, still in manuscript, on *Domestic Medicine*. He was abroad on urgent private affairs of one kind or another in 1616, from which time to his death from the plague, in 1625, nothing further concerning him remains to be noted. His life is one of those which attract the curiosity of the literary student, who knows that it is precisely in the mental and moral phases and experiences of able and active men devoid of original genius, such as he, that much of the history of an age of literature is to be read.

Lodge's works have not yet been completely reprinted, though the satisfaction of this want may no longer be far distant. His *Rosalynde* is accessible in Hazlitt's *Shakespeare's Library* (vol. iii.) and elsewhere. Its relation to Shakespeare's comedy is exhaustively discussed in an essay by Delius in the *Jahrbuch* of the German Shakespeare Society (1871). Other works of his are scattered through the publications of the old Shakespeare, the Hunterian, and possibly other Societies; lists of them will be found in the edition of *Glaucus and Silla*, &c., printed at the Chiswick Press in 1839, in Hazlitt, and elsewhere. The question, *Was Thomas Lodge an Actor?* has been set at rest by Dr C. M. Ingelby in his pamphlet bearing that title (1868), of which the main conclusion is embodied in this notice. (A. W. W.)

LODI, a city of Italy, in the province of Milan, lies on the right bank of the Adda, in 45° 18' N. lat. and 9° 30' E. long. The site of the city is an eminence rising very gradually from the Lombard plain, and the surrounding country is one of the richest dairy districts in Italy. A rather plain and ungainly cathedral (1158) with a huge lateral tower, the church dell' Incoronata erected by Bramante in 1476, the Palazzo Modegnani with a fine gateway in the style of Bramante, the episcopal palace dating from 1202, and the great hospital with its cloistered quadrangle, are the most noteworthy buildings. Besides an extensive trade in cheese (Lodi making more Parmesan than Parma itself) and other dairy produce, there are manufactures of linen, silk, majolica, and chemicals. The population of the city in 1871 was 18,537.

The ancient *Laus Pompeia* lay about 5 miles west of the present city, and the site is still occupied by a considerable village, Lodi Vecchio. In the 11th century, according to Landulphus Junior, Lodi was second to Milan among the cities of northern Italy. A dispute with the archbishop of Milan about the investiture of the bishop of Lodi (1024) proved the beginning of a bitter and protracted feud between the two cities. In 1111 the Milanese laid the whole place in ruins and forbade their rivals to restore what they had destroyed, and in 1158, when in spite of this prohibition a fairly flourishing settlement had again been formed, they repeated their work in a more thorough manner. A number of the Lodigians had settled on Colle Eghezzone; and their village, the Borgo d'Isella, soon grew up under the patronage of Frederick Barbarossa into a new city of Lodi. At first subservient to the emperor, Lodi was before long compelled to enter the Lombard League, and in 1198 it formed alliance offensive and defensive with Milan. The strife between the Sommariva or aristocratic party and the Overgnaghi or democratic party was so severe that the city broke into two distinct communes. The Overgnaghi, expelled in 1226, were restored by Frederick II. who took the city after three months' siege. During the rest of the Guelph and Ghibelline struggle, and down to the beginning of the 16th century, the annals of Lodi are crowded with stirring events, connected for the most part with the general troubles of the country. In the main it was dependent on Milan. The duke of Brunswick captured it in 1625 in the interests of Spain, and it was occupied by the French (1701), by the Austrians (1706), by the king of Sardinia (1733), by the Austrians (1736), by the Spaniards (1745), and again by the Austrians (1746). On 10th May 1796 was fought the battle of Lodi between the Austrians and Napoleon, which made the latter master of Lombardy.

LODZ (Lodzi), a town of Russian Poland, in the province of Piotrkow, lies 40 miles by rail to the north of the chief town of the province, on a branch railway of the line between Warsaw and Vienna. Only a small hamlet with 800 inhabitants in 1821, when its woollen manufactures were first introduced by Germans, it is now the second town of Poland, both by population and by importance of its cotton-mills, the annual production of which amounts to a value of about £150,000, that is, five-sixths of the whole production of cottons in Poland, as well as the other less important industries of the (woollen cloth manufacture, dyeing, and so on), is in the hands of Germans, and thus the German law predominates in the town. Although its population in 1872 amounted to 50,500, Lodz still maintains its village character, consisting of one broad street 7 miles long, on which are situated alike the factories, the houses of the merchants, and the dwellings of the working men.

LOFOTEN and VESTERAALEN, a "fogdri" or bailiwick in the "amt" of Nordland, Norway, consists of a large

A picturesque group of islands lying north-east and south-west off the north-west coast of Norway, between  $67^{\circ}30'$  and  $69^{\circ}20'$  N. lat. and between  $12^{\circ}$  and  $16^{\circ}35'$  E. long. The extreme length of the group from Andenes, at the north of Andö, to Röst, is about 130 English miles; the aggregate area amounts to about 1560 square miles, supporting a permanent population of about 20,000. It is separated from the mainland by the Vestfjord, Tjeldsund, and Vaagsfjord, and is itself divided into two sections by the Raftsund between Hindö and Öst-Vaagö: to the west and south of the Raftsund lie the Lofoten Islands proper, of which the most important are Öst-Vaagö, Gimsö, Vest-Vaagö, Flakstadö, Moskenesö, Mosken, Värö, and Röst; east and north of the Raftsund are the islands of Vesteraalen, the chief being Hindö, Ulvö, Langö, Skogsö, and Andö. The islands, which are all of granite or metamorphic gneiss, are precipitous and lofty; the highest peaks are in the Lofoten group, Vaagekallan on Öst-Vaagö rising directly from the sea to a height of 3090 feet. The channels which separate them are narrow and tortuous, and generally of great depth; they are remarkable for the strength of their tidal currents, particularly the Raftsund mentioned above, and the once famous Malström or Moskenström between Moskenes and Mosken. Though situated wholly within the Arctic Circle, the Lofoten and Vesteraalen group enjoys a climate that cannot be called rigorous when compared with that of the rest of Norway. The isothermal line which marks a mean January temperature of  $32^{\circ}$  F. runs south from the Lofotens, passing a little to the east of Bergen onwards to Gothenburg and Copenhagen. The prevailing winds are those from the south and west; the mean temperature for the year is  $38^{\circ}5$  F., and the annual rainfall is 43.34 inches. In summer the hills have only patches of snow, the snow limit being about 3000 feet. The natural pasture produced in favourable localities permits the rearing of cattle to some extent; but the growth of cereals (chiefly barley, which here matures in ninety days) is insignificant. A few potatoes are planted. The islands yield no wood. The great and characteristic industry of the district, and an important source of the national wealth, is the cod fishery which is carried on along the east coast of the Lofotens in the Vestfjord from January to April. It employs about 18,000 men from all parts of Norway; the annual take of cod amounts to an average of twenty millions, worth on the spot about £250,000. The fish, which is dried during early summer, is exported principally to Spain (where it is known as bacalao), but also to Hålland, Sweden, and Belgium. Other industries arising out of the fishery are the manufacture of cod-liver oil and of artificial manure. The herring cod fisheries and the lobster fishery are also valuable. The herring is frequently taken in large quantities off the west coasts of Vesteraalen, but is a somewhat capricious visitant. The bailiwick contains no town properly so called, but Kabelvaag on Öst-Vaagö and Solvær on a few rocky islets off that island are considerable centres of trade and (in the fishing season) of population; ingen also, at the head of the Vestfjord on Hindö, is much frequented as a port of call. Regular means of communication are afforded by the steamers which trade between Hamburg or Christiania and Hammerfest, and by local vessels; less accessible spots can be visited by means of boats, in the management of which the natives are adepts. There are some roads on Hindö, Langö, and Andö. The largest island in the group, and indeed in Norway, is Hindö, with an area of 864 square miles. The eastern portion of it belongs to the amt of Tromsö. In the island of Andö there is a bed of coal at the mouth of the Rånnes which is likely to prove ultimately of some practical value.

LOG. The ordinary log for ascertaining the speed of a ship consists of four parts, viz., the log-glass, log-line, log-reel, and log-ship. The word log may have been derived from the fact that a piece of wood was thrown overboard, to lie as a log in a fixed position, motionless; now the same name is applied to many contrivances and ingenious inventions for indicating directly, or for registering, the ship's progress through the water.

Though such information now appears to be so essential, nay, imperatively necessary to the safe conduct of a ship, it is a fact that no such simple means as the log and line was devised before the 17th century, or the subject even thought of theoretically before 1570. At least nothing can be found in ancient writings, or even in the works professedly treating upon navigation, till after 1620, while, on the contrary, various passages occur from which we may fairly infer that there was nothing better at the command of the mariner than a rough unassisted estimate. The work of Martin Cortes (Seville, 1556), after giving much valuable information for that day, including a description and use of the cross-staff, astrolabe, &c., a table of the sun's declination, with much else, makes no other reference to the ship's motion through the water than this,—the pilot must estimate the distance, making allowance for the effects of winds and currents, every day, and as the estimation "is imperfect, especially in a long voyage and long time, it is convenient that he should rectify his position by the corresponding position of the heavens." Mr J. Tapp, who published a translation and improved edition of Martin Cortes fifty-three years after (1609), made no alteration in that part of the work.

In 1578 William Bourne published *Inventions and Devices*. There are one hundred and thirteen subjects treated of, many of them highly interesting, as they contain the crude germ of useful inventions. The twenty-first device is a close approach to Massey's self-registering log, which was found so useful two hundred and sixty years later. The credit of the device is ascribed to Humfray Cole; the probable date is 1570. The proposal was to have a "little small close bout" with a wheel, or wheels, and an axletree, to turn clock-work in the little boat, with dials and pointers to indicate respectively fathoms, leagues, scores of leagues, and hundreds of leagues. If a small screw rotator had been used instead of a wheel, this might have been a great success. It was only a suggestion, perhaps untried; and in common with seamen and writers about that time the author allows only 5000 feet to a mile. Edward Wright's *Certain Errors in Navigation detected and corrected* (1610) gives much new and useful information, but the nearest allusion to the ship's speed is in the part translated from the Spanish of Roderigo Samorano, under the head of finding the ship's place on the chart, called the "point of imagination." "This point doth presuppose the knowledge of two things: to wit, the rumb by which we have sailed, and that is known by the compass, and the leagues which we have run; and this hath no certainty, but is a little more or less than a good mariner according to his imagination supposeth that he hath sailed; whereof the said point took its name." In 1624 an edition of Gunter by Edward Weaver, after much valuable geometric information, proposes at chap. vi., in a long rambling manner, that an account should be kept of the ship's way. "The way that a ship maketh may be known to an old seaman by experience, by others, it may be found," as he recommends, with the log-line or by known marks on the ship's side, bearing the proportion to a league or mile, that a certain number of seconds do to an hour. So far good; but he reckons a mile as 5866 feet (214 too little), and states that seamen count in paces of 5 feet each, and 1000 to a mile, i.e., only 5000 feet. He also proposes to

divide the degrees into one hundred parts, each to be called "centosmes." The whole subject is treated as a new thing. It is stated by Purchas (1625) that Christopher Columbus (1492) deceived his crew with respect to the distance sailed from home, and that "even the pilots did not know how far they had gone" as they glided so smoothly with a continuous fair wind. Had any kind of log been hoisted, the ship's speed would have been publicly known. Mr Burnaby (*Ancient Geography*, p. 554) states that "no ancient writer has preserved any account of the mode in which ancient navigators computed distance." Following such an authority and the quotations above, we may safely agree with the statement of Purchas that it was first used in 1607. Also we know that it did not become general till many years after. In one of our best works on navigation, printed in 1843, the log is inaccurately described.

If we are surprised that so many centuries passed, and that long voyages were made, after the discovery of the compass, without any means of measuring the distance sailed, we may be almost as much so at the diversity of opinion which prevailed among seamen with regard to the length of the log-line and the length of a mile. At the present day the principle upon which this log is arranged is easily understood. The mean degree of the meridian (see vol. x. p. 198) is assumed to be 69.09 statute miles, which gives 6080 feet to the mean nautical mile, —an estimate sufficiently accurate for navigating upon any part of the sphere. The distances upon the log-line being marked by pieces of line placed between the strands and carrying the requisite number of knots, this has given the name of knot to the nautical mile. The line is marked to knots and half knots (a single knot) only; the intermediate fractions are estimated. Two measurements are now in common use; that in the British navy is 47 feet 3 inches of line for each knot made per hour, which corresponds with a twenty-eight second glass, —thus  $(28 \times 6080) = 3600 = 47.28$  feet; in the merchant service a knot is 50 feet 7 inches, which is the correct proportion to a mile with the half minute glass. When a ship is going more than five or six knots, a short glass is used, fourteen or fifteen seconds, then the indications by the line are doubled. The shorter measure was probably chosen in consequence of the custom in vogue till about 1833 of marking the run on the log-board, or book, in knots and fathoms (or sea furlongs); the fractions are now invariably entered as tenths. The whole length of line is 60 to 80 fathoms, according to the speed anticipated; 10 to 20 fathoms of which is allowed as stray line, that the log-ship may be in a fair position, before the rag of hanting called the turn mark passes the hand. The line should be stretched and well wet before it is measured, and should be remeasured every day at sea. The inner end of the line is made fast to a light reel upon which it is wound.

The "log-ship" (fig. 1) is a piece of wood about  $\frac{1}{2}$  inch thick and the fourth part of a circle, having a radius of 5 or 6 inches, weighted with lead round the curve in order to keep it upright in the water, but not to sink it. Two holes are bored, about  $1\frac{1}{2}$  inches from the lower angles; through one a short piece of line is passed and knotted; the other end of the line has a bone or hard peg splined to it, which is inserted in the other hole, thus forming a span by which it is attached to the log-line, and hangs square.

When the log is used, a man holds the reel over his head, the officer places the peg in the log-ship, and throws it well clear of the wake, then allows it to run the "stray

line" off without assistance, steadying it just before the turn mark comes to hand; as the mark passes he calls to his assistant with the glass to "turn." As the sand runs pay out freely till the word "stop" is expected, then bring the line into a state of tension similar to what it was in when the turn mark passed. At the word "stop" nip the line instantly, count the nearest knots, and estimate the tenths. When the line is stopped the strain should cause the peg to draw from the log-ship, and it can easily be hauled in. In ships of war it is hoisted every hour. The value of the operation depends, of course, entirely upon the care bestowed.

**Ground-Log.**—In large rivers, such as Rio de la Plata, where a strong current runs, and shoals are found out of the sight of land, a lead of four or five pounds weight is used instead of the log-ship; the lead rests on the bottom, the line and sand-glass being used in a manner similar to that above described. This is called the ground-log, and indicates the speed at which the ship is passing over the ground, irrespective of currents or tides; it will show also the lateral effect of current as it is hauled in; this is the only log which can do so.

The sand-glasses are very primitive contrivances for measuring the requisite number of seconds; they are much affected by damp and change of temperature, and no reliance can be placed on their accuracy. In 1868 a timepiece sounding a gong at the required intervals was devised by the late Admiral Sir Walter Tarleton, and was tried on board some of Her Majesty's ships, but failed after a short time from damp or other causes. The writer of this article was then attempting to produce a log-gong, but abandoned it on being told that they could be obtained below his estimated cost.

**Screw Logs.**—In 1725 Henry de Saumarez described a machine which was to supersede the ordinary log. This was on the principle of the screw, having vanes which caused it to revolve and communicate a rotary motion to a piece of rope; this most probably went inboard to clockwork; hence the failure. Mr Smeaton made many experiments about 1751; he found the results very irregular, especially at high velocities, just as the writer of this article did with one of Massey's flies and a line or wire attached to a spindle, supported by large friction rollers inboard; both experiments were dead failures on account of the friction. In 1773 two screw logs were tried on board H.M. ship "Racehorse" during a short voyage to the Polar Sea; each was made to communicate motion to a counter inboard. In 1792 Mr Gower took out a patent for a screw log. None of these experiments were sufficiently successful to gain the confidence of seamen.

We see that the principle was not new in 1834 when Mr Massey patented a screw log, which has been so generally adopted that it deserves special notice and description. Though Massey took out other patents, and others have followed with modifications, the principle of all is the same, and likely to remain in use with the "common log" for many years to come. Massey fitted his log to the stern-post of a few vessels, a vertical spindle conveying the rotations of the fly to a register in the cabin above, but it did not answer.

The log of 1836 which came into general use is represented in

fig. 2. It consists of two parts united by 2 or 3 feet of rope. The "fly" consists of a hollow copper cylinder about 9 or 10 inches long with four fins or blades placed at a given angle, causing it to rotate once in a certain distance. The rope is attached to the fly and to a spindle which freely revolves in a brass box; an endless screw acting upon a system of wheel-work records the fractions of a mile on one dial, units upon a second, and tens up to one hundred on the third, on the same principle with the index of a gas meter.

The last patent was for the "frictionless log" shown in fig. 3, which is similar to the former except that, by dispensing with the piece of rope and part of the heavy box, it is much more compact and less liable to foul, —an accident to which all logs when towed after a ship are very liable. Walker's harpoon log is very similar

Fig. 1.

Fig. 2.

Fig. 3.

to the last of Massey's, but has a plate at the back in the shape of a harpoon to prevent the upper part from revolving. This log is now supplied to Her Majesty's ships. The fins or blades which cause the rotation in each of the logs above described are flat pieces of brass (not portions of a screw) soldered to a cylinder, which is hollow in order to diminish the tendency to sink when going slowly; but if the log be left overboard when the ship stops, the tow-line will allow it to sink about 100 feet, the pressure of water will then fill it, and there is no means provided for getting the water out. Screw logs will also at low speeds hang obliquely and be useless. Mr Friend tried a log with paddles protruding from a brass box instead of using a screw; but the plan was not adopted. However accurate the registering logs may be, an hourly log cannot be dispensed with, unless the ship be on one course during the whole twenty-four hours, or her speed be uniform; even then the old log and line should not be neglected. Both Massey and Walker are now trying logs the rotators of which are towed, while the dials for registering are on the ship's stern.

**Pressure Log.**—In 1849 the Rev. E. L. Berthon patented a log (fig. 4), indicating the speed of the ship by means of the pressure of water due to the velocity acting upon a tube about  $\frac{1}{2}$  of an inch diameter in the clear, closed at the end, protruding some 8 inches below the ship's bottom, with an aperture of about an  $\frac{1}{8}$  of an inch in diameter in the front side, near the closed end. A vane was used to turn the aperture in the direction of the ship's progress (course and leeway combined). At the upper end of the tube the same pipe a pointer indicated the amount of leeway. To take into account the effect which change of draught would produce, another pipe was used having the aperture in a neutral direction ( $41^{\circ}30'$ ) with regard to the ship's progress, so that the water was neither forced in nor drawn out. The two pipes communicated with air-vessels, which were allowed to be about half full of water; thence two flexible tubes conveyed the pressure to the ends of an inverted siphon partly filled with mercury, one leg of which forms a glass index tube, a graduated scale being placed behind it, on upon the principle that the pressure will increase according to the square of the velocity. As the specific gravity of mercury is so great, the scale even up to 16 knots is brought within a convenient compass; and it can be hung in gimbals (as a barometer) in any part of the ship. The leeway indicator in more recent fittings has been abandoned. The writer of this article first saw it in one of the Jersey packets, when she was steaming about 13 knots; it appeared to be very sensitive, and he was strongly impressed in its favour. For details respecting this log see paper by Vaughan Pendred, before the Society of Engineers, December 6, 1869.

The motions or disturbances imparted to the water by the body of the ship passing through it at high velocity must vitiate in a great degree all attempts to measure the speed by instruments placed near the hull of the ship, and under varying circumstances of draught, speed, and foulness of bottom. For the results of experiments and opinions on this point, by the late William Froude, F. R. S., and Mr R. Edmund Froude, see *Brit. Assoc. Rep.*, 1874, p. 225, and 1879, p. 210.

**Electric Log.**—In the chronological order in which we have taken various descriptions of log, the last deserving notice is Kelway's "electric log," the only such log known to the public. Its chief feature is the making and breaking of an electric circuit by means of a screw revolving in the water and an electric battery connected with the stop motion indicator. One of the difficulties

to be overcome was that of securing a chamber wherein to form the electric contacts, which should remain watertight under the pressure due to its depth below the surface of the sea, particularly in the event of the ship stopping and suffering it to sink when being towed with 50 fathoms of line. Mr Kelway now believes that he has overcome that difficulty, and his log has been tried on board several of Her Majesty's ships at Portsmouth, with satisfactory results, a screw similar to Massey's being towed, while in electric connexion with a dial on board.

What is considered by Mr Kelway to be an improved application of the principle is now (1882) on view in the International Exhibition at the Crystal Palace. It is intended that a hole should be cut in the ship's bottom, by preference in the engine-room, large enough to allow a short cylinder (fig. 5) containing the screw R to pass down below the ship's bottom. The cylinder is open in a fore-and-aft line and attached to a cage H, which is drawn up or lowered by means of a large screw G working through a stuffing box E. The iron box D containing the cage is 4 feet in height, made in three parts; the lower part (high enough to receive a sluice valve C) is to be bolted to the ship's bottom, and must, with the rest of the box, be nearly as strong; the central part is secured to the valve box and covered by a lid F, there being space enough above the sluice valve for the cage and screw.

To place the log, let the sluice valve C be lightly closed; open two small taps to let the water out of the box and to prove that the valve is acting. Open the lid, run the lowering screw through the cage, place it, secure the lid, open the sluice valve, and lower the rotator to the desired distance. The blades of the rotator are portions of a true screw. An endless screw on the spindle of the rotator communicates the revolutions to a vertical spindle M, which moves a train of wheels in a watertight box N; the last of these wheels revolves once in a mile, and on the same spindle is a wheel having eight ratchet teeth, which by moving a lever complete an electric current, which passes by the wire O to a dial placed in any part of the ship, sounding a bell and causing one hand of the dial to make a step and mark an eighth; one revolution indicates a mile, and other dials carry the register up to 100 miles. This form of electric log has, however, the disadvantage pointed out as affecting the Berthon or any log placed under the hull of a ship.

The electric towing log (by Kelway) promises to show continuously on board the ship what she is doing, while keeping a record of what has been done. A rating table would be at the dial, in any part of the ship; or several dials could be worked by the same electric current. It will be exposed to the danger of fouling seaweed, &c., as other towing logs are.

The logs now generally used are Massey's, Walker's, and a few of Berthon's, generally in conjunction with the old log-ship and line.

(H. A. M.)

LOGAN, JOHN (1748-88), a Scottish poet of some reputation, was born in 1748, and was son of George Logan, a farmer at Soutra, in East Lothian. Being destined for the church, he was in 1762 sent to study at the university of Edinburgh. After finishing his course, Logan was in 1768-69 tutor at Ulbster to the well-known Sir John Sinclair, and in 1770 he edited some of the poems of his college friend MICHAEL BRUCE (*q.v.*). This publication was for the benefit of Bruce's parents, who were in humble circumstances. In order to make up a volume he inserted some poems of his own, with some from other sources, and in his preface he stated that these could be easily distinguished without any names being attached. Of the seventeen pieces in the volume five were by Bruce, two by Bruce and Logan, eight by Logan, one by Sir James Foulis, and of one the authorship is unknown. One of the poems by Logan was "The Ode to the Cuckoo."

In 1770 Logan was licensed as a preacher by the presbytery of Edinburgh, and in 1771 was presented to the charge of South Leith, but was not inducted till 1773. In 1779 he delivered a course of lectures on the philosophy of history in St Mary's Chapel, Edinburgh. An analysis of these lectures was published in 1781 under the title of *Elements of the Philosophy of History*, and was followed by one of the lectures *On the Manners and Government of Asia*, 1781.

Logan was an active member of the committee of the General Assembly of the Church of Scotland appointed in 1775 to revise the "Translations and Paraphrases" drawn up in 1745 for use in private families, and to adapt them for public worship. The committee finished its

Fig. 5.

labours in 1781, and their collection of paraphrases is still in use. Eleven of them are the composition of Logan, and others were revised or altered by him. In the same year he published his poems in a volume which attracted so much attention that a second edition was issued in 1782. It also included the "Ode to the Cuckoo," with which Edmund Burke was so pleased that when in Edinburgh he sought out Logan and complimented him as the author of the finest ode in the English language.

In 1783 he published a tragedy called *Runnabude*, which met with little success. In 1786 he resigned his charge at South Leith, retaining part of his stipend. He then went to London, where he devoted himself to literature. He was engaged on the management of the *English Review*, and in 1788 published a pamphlet on the charges against Warren Hastings. He died in December 1788.

A work on ancient history, published that year under the name of Dr Ruthertford, rector of an academy at Uxbridge, is believed to have been the lectures written by Logan. His sermons were published in 1790-91, in two volumes, and have been several times reprinted. His poems were collected and published in 1812, with a memoir understood to be by the Rev. R. Douglas of Galashiel.

About forty years after Logan's death what may be called the Bruce-Logan controversy arose by the publication in 1836 of a life of Michael Bruce, prefixed to an edition of his poems by the Rev. Dr Mackenzie. In this work there is claimed for Bruce the authorship of sixteen of the pieces in the volume issued by Logan in 1770. Logan was at the same time charged with having retained some of Bruce's MSS. entrusted to him, which he used in the revision of the paraphrases. These statements have been reiterated with much abuse of Logan in a memoir of Bruce prefixed to an edition of his works published in 1865, by the Rev. Dr Grosut. In this edition the paraphrases written by Logan are inserted as having been written by Bruce. The evidence, however, brought against Logan in these biographies of Bruce, being nearly altogether of a hearsay character, is not of much value, and it may be urged that Logan was not blamed during his life for any such literary delinquencies. If anything can be brought against him with justice, it is his publishing as his own, with very few alterations, the second Paraphrase, which is the composition of Dr Doddridge.

Within the last few years the various pieces in the volume of Bruce's poems issued by Logan in 1770 have been subjected to careful criticism, and the statements made from personal knowledge by the Rev. Dr Robertson of Dalmeny, the college friend of Bruce and Logan, who was often referred to on the subject, must be held to be substantially correct. These will be found in a brochure by Dr David Laing, *Ode to the Cuckoo* (Edinburgh 1770), with remarks on its authorship, in a letter to J. C. Sharp, LL.D., 1873. See also a paper by J. Small in the *Brit. and For. Evan. Rev.*, 1877, and especially two papers by the Rev. R. Small, *ibid.*, 1878.

**LOGANSPOORT**, capital of Cass county, Indiana, U.S., is situated at the confluence of the Wabash and the Eel rivers, and on the Wabash and Erie canal, 75 miles north-west of Indianapolis. It is an important railway junction, and the trading centre of an extensive agricultural district—dealing in grain, pork, and timber (poplar and black walnut). The Pittsburg, Cincinnati, and St. Louis railroad maintains at this point large carriage works, occupying 25 acres, and employing 600 men. The population was 11,198 in 1880.

**LOGARITHMS.** The definition of a logarithm is as follows—If  $a$ ,  $x$ ,  $m$  are any three quantities satisfying the equation  $a^x = m$ , then  $a$  is called the base, and  $x$  is said to be the logarithm of  $m$  to the base  $a$ . This relation between  $a$ ,  $x$ ,  $m$ , may be expressed also by the equation  $x = \log_a m$ .

*Properties.*—The principal properties of logarithms are given by the equations

$$\log_a (uv) = \log_a u + \log_a v, \quad \log_a \frac{m}{n} = \log_a m - \log_a n,$$

$$\log_a n^r = r \log_a n, \quad \log_a \sqrt[r]{m} = \frac{1}{r} \log_a m,$$

which may be readily deduced from the definition of a logarithm. It follows from these equations that the logarithm of the product of any number of quantities is equal to the sum of the logarithms of the quantities, that the logarithm of the quotient of two quantities is equal

to the logarithm of the numerator diminished by the logarithm of the denominator, that the logarithm of the  $r$ th power of a quantity is equal to  $r$  times the logarithm of the quantity, and that the logarithm of the  $r$ th root of a quantity is equal to  $\frac{1}{r}$ th of the logarithm of the quantity.

Logarithms were originally invented for the sake of abbreviating arithmetical calculations, as by their means the operations of multiplication and division may be replaced by those of addition and subtraction, and the operations of raising to powers and extraction of roots by those of multiplication and division. For the purpose of thus simplifying the operations of arithmetic, the base is taken equal to 10, and use is made of tables of logarithms in which the values of  $x$ , the logarithm, corresponding to values of  $m$ , the number, are tabulated. The logarithm is also a function of frequent occurrence in analysis, being regarded as a known and recognized function like  $\sin x$  or  $\tan x$ , but in mathematical investigations the base generally employed is not 10, but a certain quantity usually denoted by the letter  $e$ , of value 2.71828 18284 . . . .

Thus in arithmetical calculations if the base is not expressed it is understood to be 10, so that  $\log m$  denotes  $\log_{10} m$ ; but in analytical formulæ it is understood to be  $e$ .

The logarithms to base 10 of the first twelve numbers to 7 places of decimals are

$\log 1 = 0.0000000$	$\log 5 = 0.6989700$	$\log 9 = 0.9542425$
$\log 2 = 0.3010300$	$\log 6 = 0.7781513$	$\log 10 = 1.0000000$
$\log 3 = 0.4771213$	$\log 7 = 0.8450980$	$\log 11 = 1.0413927$
$\log 4 = 0.6020600$	$\log 8 = 0.9030900$	$\log 12 = 1.0791812$

The meaning of these results is that

$$1 = 10^0, \quad 2 = 10^{0.3010300}, \quad 3 = 10^{0.4771213}, \dots$$

$$10 = 10^1, \quad 11 = 10^{1.0413927}, \quad 12 = 10^{1.0791812}.$$

The integral part of a logarithm is called the index or characteristic, and the fractional part the mantissa. When the base is 10, the logarithms of all numbers in which the digits are the same, no matter where the decimal point may be, have the same mantissa, thus, for example,

$$\log 25613 = 0.4084604, \quad \log 256130 = 1.4084604,$$

$$\log 2561300 = 2.4084604, \text{ \&c.}$$

In the case of fractional numbers (i.e., numbers in which the integral part is 0) the mantissa is still kept positive, so that, for example,

$$\log 25613 = \bar{1}.4084604, \quad \log .0025613 = \bar{3}.4084604, \text{ \&c.},$$

the minus sign being usually written over the characteristic, and not before it, to indicate that the characteristic only and not the whole expression is negative; thus

$$\bar{1}.4084604 \text{ stands for } -1 + .4084604.$$

The fact that when the base is 10 the mantissa of the logarithm is independent of the position of the decimal point in the number affords the chief reason for the choice of 10 as base. The explanation of this property of the base 10 is evident, for a change in the position of the decimal points amounts to multiplication or division by some power of 10, and this corresponds to the addition or subtraction of some integer in the case of the logarithm, the mantissa therefore remaining intact. It should be mentioned that in most tables of trigonometrical functions, the number 10 is added to all the logarithms in the table in order to avoid the use of negative characteristics, so that the characteristic 9 denotes in reality 1, 8 denotes 2, 10 denotes 0, &c. Logarithms thus increased are frequently referred to for the sake of distinction as *tabular logarithms*, so that the tabular logarithm = the true logarithm + 10.

In tables of logarithms of numbers to base 10 the mantissa only is in general tabulated, as the characteristic of the logarithm of a number can always be written down at sight, the rule being that, if the number is between

unity, the characteristic is less by unity than the number of digits in the integral portion of it, and that if the number is less than unity the characteristic is negative, and is greater by unity than the number of ciphers between the decimal point and the first significant figure.

It follows very simply from the definition of a logarithm that

$$\log_a b \times \log_b a = 1, \quad \log_a m = \log_a m \times \frac{1}{\log_a b}.$$

The second of these relations is an important one, as it shows that from a table of logarithms to base  $a$ , the corresponding table of logarithms to base  $b$  may be deduced by multiplying all the logarithms in the former by the constant multiplier  $\frac{1}{\log_a b}$ , which is called the *modulus* of the system whose base is  $b$  with respect to the system whose base is  $a$ .

The two systems of logarithms for which extensive tables have been calculated are the Napierian, or hyperbolic, or natural system, of which the base is  $e$ , and the Briggian, or decimal, or common system, of which the base is 10; and we see that the logarithms in the latter system may be deduced from those in the former by multiplication by the constant multiplier  $\frac{1}{\log_e 10}$ , which is called the modulus of the common system of logarithms. The numerical value of this modulus is 0.43429 44819 03251 82765 11289 ..., and the value of its reciprocal,  $\log_e 10$  (by multiplication by which Briggian logarithms may be converted into Napierian logarithms) is 2.30258 50929 94045 68401 79914 ...

The quantity denoted by  $e$  is the series,

$$1 + \frac{1}{1} + \frac{1}{1 \cdot 2} + \frac{1}{1 \cdot 2 \cdot 3} + \frac{1}{1 \cdot 2 \cdot 3 \cdot 4} + \dots$$

the numerical value of which is,

$$2.71828 18284 59045 23536 02874 \dots$$

The mathematical function  $\log x$ , or  $\log_e x$ , is one of the small group of transcendental functions, consisting only of the circular functions (direct and inverse)  $\sin x$ ,  $\cos x$ , &c., are  $\sin x$ , are  $\cos x$ , &c.,  $e^x$ , and  $\log x$ , which are universally treated in analysis as known functions. It is the inverse of the exponential function  $e^x$ , the theory of which may be regarded as including that of the circular functions, since

$$\sin x = \frac{1}{2i}(e^{ix} - e^{-ix}), \quad \cos x = \frac{1}{2}(e^{ix} + e^{-ix}).$$

There is no series for  $\log x$  proceeding either by ascending or descending powers of  $x$ , but there is an expansion for  $\log(1+x)$ , viz.:-

$$\log(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \dots;$$

the series, however, is convergent for real values of  $x$  only when  $x$  lies between +1 and -1. Other formulæ which are deducible from this equation are given in the portion of this article relating to the calculation of logarithms.

We have also the fundamental formulæ—

$$(i.) \text{ Limit of } \frac{x^h - 1}{h}, \text{ when } h \text{ is indefinitely diminished, } = \log x;$$

$$(ii.) \int \frac{dx}{x} = \log x + \text{const.}$$

Either of these results might be regarded as the definition of  $\log x$ ; they may be readily connected with one another, for we have in general

$$\int x^n dx = \frac{x^{n+1}}{n+1} + \text{const.};$$

but if  $n = -1$ , this formula no longer gives a result. Putting, however,  $n = -1 + h$ , where  $h$  is indefinitely small, we have

$$\int \frac{dx}{x} = \frac{x^h}{h} + \text{const.} = \frac{x^h - 1}{h} + \text{const.} = \log x + \text{const. by (i.).}$$

The result (ii.) establishes a relation, which is of historical interest, between the logarithmic function and the quadrature of the hyperbola; for by considering the equation of the hyperbola in the form  $xy = \text{const.}$  we see at once that the area included between the arc of a hyperbola, its nearest asymptote, and two ordinates is equal to the area included between the other asymptote from points on the first

asymptote distant  $a$  and  $b$  from their point of intersection is proportional to  $\log \frac{b}{a}$ .

The function  $\log x$  is not a *uniform* function, that is to say, if  $x$  denotes a complex variable of the form  $a+ib$ , and if complex quantities are represented in the usual manner by points in a plane, then it does not follow that if  $x$  describes a closed curve  $\log x$  also describes a closed curve; in fact we have

$$\log(a+ib) = \log \sqrt{a^2+b^2} + i(a+2n\pi),$$

where  $a$  is a determinate angle, and  $n$  denotes any integer. Thus, even when the argument is real,  $\log x$  has an infinite number of values; for, putting  $b=0$  and taking  $a$  positive, in which case  $a=0$ , we obtain for  $\log a$  the infinite system of values  $\log a + 2n\pi i$ . It follows from this property of the function that we cannot have for  $\log x$  a series which shall be convergent for all values of  $x$ , as is the case with  $\sin x$ ,  $\cos x$ , and  $e^x$ ; as such a series could only represent a uniform function, and in fact the equation

$$\log(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \dots,$$

is true only when the analytical modulus of  $x$  is less than unity.

The notation  $\log x$  is generally employed in English works, but Continental writers usually denote the function by  $L$  or  $\lg x$ .

*History.*—The invention of logarithms has been accorded to John Napier, baron of Merchiston, in Scotland, with a unanimity which is rare with regard to important scientific discoveries. The first announcement was made in Napier's *Mirifici logarithmorum canonis descriptio* (Edinburgh, 1614), which contains an account of the nature of logarithms, and a table giving natural sines and their logarithms for every minute of the quadrant to seven or eight figures. These logarithms are not what would now be called Napierian or hyperbolic logarithms (i.e., logarithms to the base  $e$ ), though closely connected with them, the relation between the two being

$$L = 10^7 \log_e 10^7, \quad \text{or } L = 10^7 \log_e 10^7 - 10^7,$$

where  $l$  denotes the logarithm to base  $e$  and  $L$  denotes Napier's logarithm. The relation between  $N$  (a sine) and  $L$  its Napierian logarithm is therefore

$$N = 10^7 e^{-\frac{L}{10^7}},$$

and the logarithms decrease as the sines increase. Napier died in 1617, and his posthumous work *Mirifici logarithmorum canonis constructio*, explaining the mode of construction of the table, appeared in 1619, edited by his son.

Henry Briggs, then professor of geometry at Gresham College, London, and afterwards Savilian professor of geometry at Oxford, admired the *Canon mirificus* so much that he resolved to visit Napier. In a letter to Ussher he writes, "Naper, lord of Markinston, hath set my head and hands at work with his new and admirable logarithms. I hope to see him this summer, if it please God; for I never saw a book which pleased me better, and made me more wonder." Briggs accordingly visited Napier in 1615, and stayed with him a whole month. He brought with him some calculations he had made, and suggested to Napier the advantages that would result from the choice of 10 as a base, having explained them previously in his lectures at Gresham College, and written to Napier on the subject. Napier said that he had already thought of the change, and pointed out a slight improvement, viz., that the characteristics of numbers greater than unity should be positive and not negative, as suggested by Briggs. In 1616 Briggs again visited Napier and showed him the work he had accomplished, and, he says, he would gladly have paid him a third visit in 1617 had Napier's life been spared.

Briggs's *Logarithmorum chilias prima* was published, probably privately, in 1617, after Napier's death, as in the short preface he states that why his logarithms are different from those introduced by Napier "sperandum, ejus librum posthumum abunde nobis propediem satisfacturum." The *liber posthumus* was the *Canonis constructio* already mentioned. This work of Briggs, which contains the

first published table of decimal or common logarithms, is only a small octavo tract of sixteen pages, and gives the logarithms of numbers from unity to 1000 to 14 places of decimals. There is no author's name, place, or date. The date of publication is, however, fixed as 1617 by a letter from Sir Henry Bouchier to Ussher, dated December 6, 1617, containing the passage—"Our kind friend, Mr Briggs, hath lately published a supplement to the most excellent tables of logarithms, which I presume he has sent to you." Briggs's tract of 1617 is extremely rare, and has generally been ignored or incorrectly described. Hutton erroneously states that it contains the logarithms to 8 places, and his account has been followed by most writers. There is a copy in the British Museum.

Briggs continued to labour assiduously at the calculation of logarithms, and in 1624 published his *Arithmetica logarithmica*, a folio work containing the logarithms of the numbers from 1 to 20,000, and from 90,000 to 100,000 (and in some copies to 101,000) to 14 places of decimals. The table occupies 300 pages, and there is an introduction of 88 pages relating to the mode of calculation of the tables, and the applications of logarithms.

There was thus left a gap between 20,000 and 90,000, which was filled up by Adrian Vlacq, who published at Gouda, in Holland, in 1628, a table containing the logarithms of the numbers from unity to 100,000 to 10 places of decimals. Having calculated 70,000 logarithms and copied only 30,000, Vlacq would have been quite entitled to have called his a new work. He designates it, however, only a second edition of Briggs's *Arithmetica logarithmica*, the title running *Arithmetica logarithmica sive logarithmorum chiliades centum, . . . Editio secunda aucta per Adrianum Vlacq, Goudanum*. This table of Vlacq's was published, with an English explanation prefixed, at London in 1631 under the title *Logarithmicall Arithmetike . . . London, printed by George Miller, 1631*. There are also copies with a French title page and introduction (Gouda, 1628).

Briggs had himself been engaged in filling up the gap, and in a letter to Pell, written after the publication of Vlacq's work, and dated October 25, 1628, he says:—

"My desire was to have those chiliades that are wanting between 20 and 90 calculated and printed, and I had done them all almost by my selfe, and by some frendes whom my rules had sufficiently informed, and by agreement the busines was conveniently parted amongst us; but I am eased of that charge and care by one Adrian Vlacque, an Hollander, who hath done all the whole hundred chiliades and printed them in Latin, Dutche, and Frenche, 1000 bookes in these 3 languages, and hath sold them almost all. But he hath cutt off 4 of my figures throughout; and hath left out my dedication, and to the reader, and two chapters the 12 and 13, in the rest he hath not varied from me at all."

The original calculation of the logarithms of numbers from unity to 101,000 was thus performed by Briggs and Vlacq between 1615 and 1628. Vlacq's table is that from which all the hundreds of tables of logarithms that have subsequently appeared have been derived. It contains of course many errors, which have gradually been discovered and corrected in the course of the two hundred and fifty years that have elapsed, but no fresh calculation has been published. The only exception is Mr Sang's table (1871), part of which was the result of an original calculation.

The first calculation or publication of Briggian or common logarithms of trigonometrical functions was made in 1620 by Gunter, who was Briggs's colleague as professor of astronomy in Gresham College. The title of Gunter's book, which is very scarce, is *Canon triangulorum*, and it contains logarithmic sines and tangents for every minute of the quadrant to 7 places of decimals.

(The next publication was due to Vlacq, who appended to his logarithms of numbers in the *Arithmetica logarithmica*

of 1628 a table giving log sines, tangents, and secants for every minute of the quadrant to 10 places; these were obtained by calculating the logarithms of the natural sines, &c., given in the *Thesaurus Mathematicus* of Pitiscus (1613).

During the last years of his life Briggs devoted himself to the calculation of logarithmic sines, &c., and at the time of his death in 1631 he had all but completed a logarithmic canon to every hundredth of a degree. This work was published by Vlacq at his own expense at Gouda in 1633, under the title *Trigonometria Britannica*. It contains log sines (to 14 places) and tangents (to 10 places), besides natural sines, tangents, and secants, at intervals of a hundredth of a degree. In the same year Vlacq published at Gouda his *Trigonometria artificialis*, giving log sines and tangents to every 10 seconds of the quadrant to 10 places. This work also contains the logarithms of the numbers from unity to 20,000 taken from the *Arithmetica logarithmica* of 1628. Briggs appreciated clearly the advantages of a centesimal division of the quadrant, and by dividing the degree into hundredth parts instead of into minutes, made a step towards a reformation in this respect, and but for the appearance of Vlacq's work the decimal division of the degree might have become recognized, as is now the case with the corresponding division of the second. The calculation of the logarithms not only of numbers but also of the trigonometrical functions is therefore due to Briggs and Vlacq; and the results contained in their four fundamental works—*Arithmetica logarithmica* (Briggs), 1624; *Arithmetica logarithmica* (Vlacq), 1628; *Trigonometria Britannica* (Briggs), 1633; *Trigonometria artificialis* (Vlacq), 1633—have never been superseded by any subsequent calculations.

A translation of Napier's *Descriptio* was made by Edward Wright, whose name is well known in connexion with the history of navigation, and after his death published by his son at London in 1616 under the title *A Description of the admirable Table of Logarithmes* (12mo); the edition was revised by Napier himself. Both the *Descriptio* (1614) and the *Constructio* (1619) were reprinted at Lyons in 1620 by Bartholomew Vincent, who thus was the first to publish logarithms on the Continent.

Napier calculated no logarithms of numbers, and, as already stated, the logarithms invented by him were not to base  $e$ . The first logarithms to the base  $e$  were published by John Speidell in his *New Logarithmes* (London, 1619), which contains hyperbolic log sines, tangents, and secants for every minute of the quadrant to 5 places of decimals.

In 1624 Benjamin Ursinus published at Cologne a canon of logarithms exactly similar to Napier's in the *Descriptio* of 1614, only much enlarged. The interval of the arguments is 10", and the results are given to 8 places; in Napier's canon the interval is 1', and the number of places is 7. The logarithms are strictly Napierian, and the arrangement is identical with that in the canon of 1614. This is the largest Napierian canon that has ever been published.

Kepler took the greatest interest in the invention of logarithms, and in 1624 he published at Marburg a table of Napierian logarithms of sines, with certain additional columns to facilitate special calculations.

The first publication of Briggian logarithms on the Continent is due to Wingate, who published at Paris in 1625 his *Arithmétique logarithmétique*, containing seven-figure logarithms of numbers up to 1000, and log sines and tangents from Gunter's *Canon* (1620). In the following year, 1626, Denis Henrion published at Paris a *Traicté des Logarithmes*, containing Briggs's logarithms of numbers up to 20,001 to 10 places, and Gunter's log sines and tangents to 7 places for every minute. In the same year De Decker also published at Gouda a work entitled *Nieuwe Telkonst, inhoudende de Logarithmi voor de Ghetallen beginnende van*

1 to 10,000, which contained logarithms of numbers up to 10,000 to 10 places, taken from Briggs's *Arithmetica* of 1624, and Gunter's log sines and tangents to 7 places for every minute. Vlacq rendered assistance in the publication of this work, and the privilege is made out to him.

The preceding paragraphs contain a brief account of the main facts relating to the invention of logarithms. In describing the contents of the works referred to the language and notation of the present day have been adopted, so that for example a table to radius 10,000,000 is described as a table to 7 places, and so on. Also, although logarithms have been spoken of as to the base  $e$ , &c., it is to be noticed that neither Napier nor Briggs, nor any of their successors till long afterwards, had any idea of connecting logarithms with exponents.

The invention of logarithms and the calculation of the earlier tables form a very striking episode in the history of exact science, and, with the exception of the *Principia* of Newton, there is no mathematical work published in the country which has produced such important consequences, or to which so much interest attaches as to Napier's *Descriptio*. The calculation of tables of the natural trigonometrical functions may be said to have formed the work of the last half of the 16th century, and the great canon of natural sines for every 10 seconds to 15 places which had been calculated by Rheticus was published by Pitiscus only in 1613, the year before that in which the *Descriptio* appeared. In the construction of the natural trigonometrical tables England had taken no part, and it is remarkable that the discovery of the principles and the formation of the tables that were to revolutionize or supersede all the methods of calculation then in use should have been so rapidly effected and developed in a country in which so little attention had been previously devoted to such questions.

The only possible rival to Napier in the invention of logarithms is Justus Byrgius, who about the same time constructed a rude kind of logarithmic or rather anti-logarithmic table; but there is every reason to believe that Napier's system was conceived and perfected before that of Byrgius; and in date of publication Napier has the advantage by six years. The title of the work of Byrgius is *Arithmetische und geometrische Progress-Tabulen*; in his table he has  $\log 1 = 0$  and  $\log 10 = 230270022$ . The only contemporary reference to Byrgius is contained in the sentence of Kepler, "Apices logistici Justo Byrgio multis annis ante editionem Neperianam viam præiverunt ad hos ipsissimos logarithmos," which occurs in the "Præcepta" prefixed to the *Tabulæ Rudolphinæ* (1627), the *apices* are the signs ', ', used to denote the orders of sexagesimal fractions. The system of Byrgius is greatly inferior to that of Napier, and it is to the latter alone that the world is indebted for the knowledge of logarithms. The claims of Byrgius are discussed in Kästner's *Geschichte der Mathematik*, vol. ii. p. 375, and vol. iii. p. 14; Montucla's *Histoire des Mathématiques*, vol. ii. p. 10; Delambre's *Histoire de l'Astronomie moderne*, vol. i. p. 560; De Morgan's article on "Tables" in the *English Cyclopædia*; and Mr Mark Napier's *Memoirs of John Napier of Merchiston* (1834).

An account of the facts connected with the early history of logarithms is given by Hutton in his *History of Logarithms*, prefixed to all the early editions of his logarithmic tables, and also printed in vol. i. pp. 306-340 of his *Tracts* (1812); but unfortunately Hutton has interpreted all Briggs's statements with regard to the invention of decimal logarithms in a manner clearly contrary to their true meaning, and unfair to Napier. This has naturally produced retaliation, and Mr Mark Napier has not only successfully refuted Hutton, but has fallen into the opposite extreme of attempting to reduce Briggs to the level of a mere com-

puter. It seems strange that the relations of Napier and Briggs with regard to the invention of decimal logarithms should have formed matter for controversy. The statements of both agree in all particulars, and the warmest friendship subsisted between them. Napier at his death left his manuscripts to Briggs, and all the writings of the latter show the greatest reverence for him. The words that occur on the title page of the *Logarithmicall arithmetike* of 1631 are "These numbers were first invented by the most excellent John Neper, Baron of Merchiston; and the same were transformed, and the foundation and use of them illustrated with his approbation by Henry Briggs." No doubt the invention of decimal logarithms occurred both to Napier and to Briggs independently, but the latter not only first announced the advantage of the change, but actually undertook and completed tables of the new logarithms. For more detailed information relating to Napier, Briggs, and Vlacq, and the invention of logarithms, the reader is referred to the life of Briggs in Ward's *Lives of the Professors of Gresham College*, London, 1740; Thomas Smith's *Vita quorundam eruditissimorum et illustrium virorum* (Vita Henrici Briggsii), London, 1707; Mr Mark Napier's *Memoirs of John Napier* already referred to, and the same author's *Naperi libri qui supersunt* (1839); Hutton's *History*; De Morgan's article already referred to, Delambre's *Histoire de l'Astronomie Moderne*, the report on mathematical tables in the *Report of the British Association* for 1873; and the *Philosophical Magazine* for October and December 1872 and May 1873. It may be remarked that the date usually assigned to Briggs's first visit to Napier is 1616 and not 1615 as stated above, the reason being that Napier was generally supposed to have died in 1618; but it was shown by Mr Mark Napier that the true date is 1617.

For a description of existing logarithmic tables, and the purposes for which they were constructed, the reader is referred to the article TABLES (MATHEMATICAL). In what follows only the most important events in the history of logarithms, subsequent to the facts connected with their invention and the original calculations, will be noticed.

Nathaniel Roe's *Tabulæ logarithmicæ* (1633) was the first complete seven-figure table that was published. It contains seven-figure logarithms of numbers from 1 to 100,000, with characteristics inseparable from the mantissa, and was formed from Vlacq's table (1628) by leaving out the last three figures. All the figures of the number are given at the heads of the columns, except the last two, which run down the extreme columns. 1 to 50 on the left hand side, and 50 to 100 on the right hand side. The first four figures of the logarithms are printed at the tops of the columns. There is thus nearly one half way towards the arrangement now universal in seven-figure tables. The final step was made by John Newton in his *Trigonometria Eritanica* (1658), a work which is also noticeable as being the only extensive eight-figure table that has ever been published; it contains logarithms of sines, &c., as well as logarithms of numbers.

In 1705 appeared the original edition of Sherwin's tables, the first of the series of ordinary seven-figure tables of logarithms of numbers and trigonometrical functions such as are in general use now. The work went through several editions during the last century, and was at length superseded in 1795 by Hutton's tables, which have continued in successive editions to maintain their position up to the present time.

In 1717 Abraham Sharp published in his *Geometrical Tables* the Briggsian logarithms of numbers from 1 to 100, and of primes from 100 to 1100, to 61 places; these were copied into the later editions of Sherwin and other works.

In 1742 a seven-figure table was published in quarto form by Gardiner, which is celebrated on account of its accuracy and of the elegance of the printing. A French edition, which closely resembles the original, was published at Avignon in 1770.

In 1783 appeared at Paris the first edition of Callet's tables, which correspond to those of Hutton in England. These tables, which form perhaps the most complete and practically useful collection of logarithms for the general computer that has been published, have passed through many editions, and are still in use.

In 1794 Vega published his *Thesaurus logarithmorum completus*, a folio volume containing a reprint of the logarithms of numbers

from Vlacq's *Arithmetica logarithmica* of 1628, and *Trigonometria artificialis* of 1633. The logarithms of numbers are arranged as in an ordinary seven-figure table. In addition to the logarithms reprinted from the *Trigonometria*, there are given logarithms for every second of the first two degrees, which were the result of an original calculation. Vega devoted great attention to the detection and correction of the errors in Vlacq's work of 1628. He also published in 1797, in 2 vols. 8vo, a collection of logarithmic and trigonometrical tables which has passed through many editions, a very useful one volume stereotype edition having been published in 1840 by Hulse. The tables in this work may be regarded as to some extent supplementary to those in Callet.

If we consider only the logarithms of numbers, the main line of descent from the original calculation of Briggs and Vlacq is Roe, John Newton, Sherwin, Gardiner; there are then two branches, viz., Hutton founded on Sherwin and Callet on Gardiner, and the editions of Vega form a separate offshoot from the original tables. Among the most useful and accessible of modern ordinary seven-figure tables of logarithms of numbers and trigonometrical functions may be mentioned those of Bremiker, Schron, and Bruhns. For logarithms of numbers only perhaps Babbage's table is the most convenient.

In 1871 Mr Sang published a seven figure table of logarithms of numbers extending from 20,000 to 200,000; and the logarithms of the numbers between 100,000 and 200,000 were calculated *de novo* by Mr Sang as if logarithms had never been computed before. In tables extending from 10,000 to 100,000 the differences near the beginning of the table are large, and they are so numerous that the proportional parts must either be very crowded, or some of them have to be omitted; and to diminish this inconvenience many tables extend to 108,000. By beginning the table at 20,000 instead of at 10,000, the differences are halved in magnitude, while the number of them in a page is quartered. In this table multiples of the differences, instead of proportional parts, are given.

As regards the logarithms of trigonometrical functions, the next great advance on the *Trigonometria artificialis* took place more than a century and a half afterwards, when Michael Taylor published in 1792 his seven-decimal table of log sines and tangents to every second of the quadrant; it was calculated by interpolation from the *Trigonometria* to 10 places and then contracted to 7. On account of the great size of this table, and for other reasons, it never came into very general use. Bagay's *Nouvelles tables astronomiques* (1829), which also contains log sines and tangents to every second, being preferred, but this work is now difficult to procure. The only other logarithmic canon to every second that has been published forms the second volume of Shortrede's *Logarithmic Tables* (1849). It contains also proportional parts, and is the most complete and accessible table of logarithms for every second. Shortrede's tables originally appeared in 1844 in one volume, during the author's absence in India, but, not being satisfied with them in some respects, he made various alterations, and published a second edition in two volumes in 1849. There have been subsequent editions of the volume containing the trigonometrical canon. The work is an important one, and the pages are clear, although the number of figures on each is very great.

On the proposition of Carnot, Prieur, and Brunet, the French Government decided in 1784 that new tables of sines, tangents, &c., and their logarithms, should be calculated in relation to the centesimal division of the quadrant. Prony was charged with the direction of the work, and was expressly required "Non seulement à composer des tables qui ne laissent rien à désirer quant à l'exécution, mais à en faire le monument de calcul le plus vaste et le plus imposant qui eût jamais été exécuté ou même conçu." Those engaged upon the work were divided into three sections: the first consisted of five or six mathematicians, including Legendre, who were engaged in the purely analytical work, or the calculation of the fundamental numbers; the second section consisted of seven or eight calculators possessing some mathematical knowledge; and the third comprised seventy or eighty ordinary computers. The work, which was performed wholly in duplicate, and independently by two divisions of computers, occupied two years. As a consequence of the double calculation, there are two manuscripts in existence, one of which is deposited at the Observatory, and the other in the library of the Institute, at Paris. Each of the two manuscripts consists essentially of seventeen large folio volumes, the contents being as follows:—

Logarithms of numbers	up to 200,000	8 vols.
Natural sines		1 "
Logarithms of the ratios of arc	sines from 0° 00'00" to 0° 05'00", and log sines throughout quadrant	
Logarithms of the ratio of	s to tangents from 0° 00'00" to 0° 05'00", and log tangent	4
	throughout the quadrant	

The trigonometrical results are given for every hundred-thousandth of the quadrant (10" centesimal or 3" 24 sexagesimal). The tables were all calculated to 14 places, with the intention that only 12 should be published, but the twelfth figure is not to be relied upon. The tables have never been published, and are

generally known as the *Tables du Cadastre*, or, in England, as the great French manuscript tables.

A very full account of the *Tables du Cadastre*, with an explanation of the methods of calculation, formulae employed, &c., has been published by M. Lefort in vol. iv. of the *Annales de l'Observatoire de Paris*. The printing of the table of natural sines was once begun, and M. Lefort states that he has seen six copies, all incomplete, although including the last page. Babbage compared his table with the *Tables du Cadastre*, and M. Lefort has given in his paper just referred to most important lists of errors in Vlacq's and Briggs's logarithms of numbers which were obtained by comparing the manuscript tables with those contained in the *Arithmetica logarithmica* of 1624 and of 1628. These are almost the only uses that have been made of the French tables, the calculation of which involved so great an expenditure of time and money.

It may be mentioned here that the late Mr John Thomson of Greenock made an independent calculation of the logarithms of numbers up to 120,000 to 12 places, and that the manuscript of the table was presented in 1874 to the Royal Astronomical Society by his sister. The table has been used to verify the errata which M. Lefort found in Vlacq and Briggs by means of the *Tables du Cadastre*. An account of Mr Thomson's table, and of this and other comparisons between it and the printed tables, is to be found in the *Monthly Notices of the Society*, vol. xxxiv. pp. 447-75 (1874).

Although the *Tables du Cadastre* have never been published, other tables have appeared in which the quadrant is divided centesimally, the most important of these being Hobert and Ideler's *Nouvelles tables trigonométriques* (1799), and Borda and Delambre's *Tables trigonométriques décimales* (1800-1). The former work contains natural and log sines, cosines, tangents, and cotangents to 7 places, up to 3° (centesimal) at intervals of 10" (centesimal), and thence to 50° at intervals of 1'. The latter gives log sines, cosines, tangents, and cosines for centesimal arguments, viz., from 0° to 10° at intervals of 10", and from 0° to 50° at intervals of 10', to 11 places, and also, in another table, log sines, cosines, tangents, cotangents, secants, and cosecants from 0° to 8° at intervals of 10", and thence to 50° at intervals of 1' to 7 places. After the work was printed it was read by Delambre with the *Tables du Cadastre*, and a number of last-figure errors which are given in the preface were thus detected. Callet's tables already referred to contain in a convenient form logarithms of trigonometrical functions for centesimal arguments.

Two tables of logarithms of numbers which have been recently published may be noticed, as they involve points of novelty. The first of these is Pinet's *Tables de logarithmes* (St Petersburg, 1871). The tables are intended to give in a small space (66 pages) all the results that can be obtained from a complete ten-figure table by means of the following principle:—only the logarithms of the numbers from 1,000,000 to 1,011,000 are given directly, all other numbers being brought within the range of this table by multiplication by a factor, the logarithm of which factor is to be subtracted from the logarithm in the table. A list of the most convenient factors and their logarithms is given in a separate table. The principle of multiplying by a factor which is subsequently cancelled by subtracting its logarithm is one that is frequently employed in the calculation of logarithms, but the peculiarity of the present work is that it forms part of the process of using the table. The other tables, which occupy only ten pages, were published in a tract entitled *Tables de logarithmes à 12 décimales jusqu'à 434 milliards* by MM. Namur and Mansior at Brussels in 1877. The fact that the differences of the logarithms of numbers near to 434294 (these being the first figures of the modulus of the Briggsian logarithms) commenced with the figures 100..., so that the interpolations in this part of the table are very easily and accurately performed, is ingeniously made use of. A table is given of logarithms of numbers near to 434294, and other numbers are brought within the range of the table by multiplication by one or two factors which are indicated.

In the ordinary tables of logarithms the natural numbers are all integers, while the logarithms tabulated are incommensurable. In an antilogarithmic table, the logarithms are exact quantities such as '00001, '00002, &c., and the numbers are incommensurable. The earliest and largest table of this kind that has been constructed is Dodson's *Antilogarithmic canon* (1742), which gives the numbers to 11 places, corresponding to the logarithms from '00001 to '99999 at intervals of '00001. The only other extensive tables of the same kind that have been published occur in Shortrede's *Logarithmic tables* already referred to, and in Filipowski's *Table of antilogarithms* (1849). Both are similar to Dodson's tables, from which they were derived, but they only give numbers to 7 places.

The most elaborate table of hyperbolic logarithms that exists is due to Wolfram, a Dutch lieutenant of artillery. His table gives the logarithms of all numbers up to 2200, and of primes (and also of a great many composite numbers) from 2200 to 10,000, to 48 decimal places. The table appeared in Schulze's *Neue und erweiterte Sammlung logarithmischer Tafeln* (1778), and was reprinted in Vega's *Thesaurus* (1794), already referred to. It

logarithms omitted in Schulze's work, and which Wölfgram had been prevented from computing by a serious illness, were published subsequently, and the table as given by Vega is complete. The largest hyperbolic table as regards range was published by Zacharias Dase at Vienna in 1850 under the title, *Tafel der natürlichen Logarithmen der Zahlen*. It gives hyperbolic logarithms of numbers from 1000·0 to 10500·0 at intervals of ·1 to 7 places, with differences and proportional parts, arranged like an ordinary seven-figure table of Briggsian logarithms. The table appeared in the thirty-fourth part (new series, vol. xiv.) of the *Annals of the Vienna Observatory* (1851); but separate copies were issued.

Hyperbolic antilogarithms are simple exponentials, i.e., the hyperbolic antilogarithm of  $x$  is  $e^x$ . A seven-figure table of  $e^x$  and its Briggsian logarithm from  $x=0·1$  to  $x=10$  at intervals of ·01 is given in Hülse's edition of Vega's *Sammlung*, and in other collections of tables; but by far the most complete table that has been published occurs in Gudermann's *Theorie der potenzial- oder cyklich-hyperbolischen Functionen*, Berlin, 1833. This work consists of reprinted papers from Crelle's *Journal*, and one of the tables contains the Briggsian logarithms of the hyperbolic sine, cosine, and tangent of  $x$  from  $x=2$  to  $x=5$  at intervals of ·001 to 9 places, and from  $x=5$  to  $x=12$  at intervals of 0·01 to 10 places. Since the hyperbolic sine and cosine of  $x$  are respectively  $\frac{1}{2}(e^x - e^{-x})$  and  $\frac{1}{2}(e^x + e^{-x})$ , the values of  $e^x$  and  $e^{-x}$  may be deduced from the results given in the table by simple addition and subtraction.

*Logistic numbers* is the old name for what would now be called ratios or fractions. Thus a table of  $\log \frac{a}{x}$ , where  $x$  is the argument and  $a$  a constant, is called a table of logistic or proportional logarithms; and since  $\log \frac{a}{x} = \log a - \log x$  it is clear that the tabular results differ from those given in an ordinary table of logarithms only by the subtraction of a constant and a change of sign. The first table of this kind appeared in Kepler's *Chilias logarithmorum* (1624) already referred to. The object of a table of  $\log \frac{a}{x}$  is to

facilitate the working out of proportions in which the third term is a constant quantity  $a$ . In most collections of tables of logarithms, and especially those intended for use in connexion with navigation, there occurs a small table of logistic logarithms in which  $a=3600''$  ( $=1^\circ$  or  $1^h$ ), the table giving  $\log 3600 - \log x$ , and  $x$  being expressed in minutes and seconds. It is also common to find tables in which  $a=10800''$  ( $=3^\circ$  or  $3^h$ ), and  $x$  is expressed in degrees (or hours), minutes, and seconds. Such tables are generally given to 4 or 5 places. The usual practice in books seems to be to call logarithms logistic when  $a$  is 3600'', and proportional when  $a$  has any other value.

*Gaussian logarithms* are intended to facilitate the finding of the logarithms of the sum and difference of two numbers whose logarithms are known, the numbers themselves being unknown; and on this account they are frequently called addition and subtraction logarithms. The object of the table is in fact to give  $\log(a \pm b)$  by only one entry when  $\log a$  and  $\log b$  are given. The utility of such logarithms was first pointed out by Leonelli in a book entitled *Supplément logarithmique*, printed at Bordeaux in the year XI. (1802-3); this work being very scarce, a reprint of it was published by M. J. Houel in 1876. Leonelli calculated a table to 14 places, but only a specimen of it which appeared in the *Supplément* was printed. The first table that was actually published is due to Gauss, and was printed in Zach's *Monatliche Correspondenz*, vol. xxvi. p. 498 (1812). Corresponding to the argument  $A$  it gives, to 5 places,  $B$  and  $C$ , where

$$A = \log x, \quad B = \log \left(1 + \frac{1}{x}\right), \quad C = \log(1+x)$$

so that  $C = A + B$ .

We have identically

$$\log(a+b) = \log a + \log \left(1 + \frac{b}{a}\right) = \log a + B \text{ (for argument } \log \frac{a}{b});$$

and, in using the table, the rule is to take  $\log a$  to be the larger of the two logarithms, and to enter the table with  $\log a - \log b$  as argument; we then have  $\log(a+b) = \log a + B$ , or, if we please,  $= \log b + C$ . The formula for the difference is  $\log(a-b) = \log b + A$  (argument sought in column C) if  $\log a - \log b$  is greater than ·30103 and  $= \log b - A$  (argument sought in column B) if  $\log a - \log b$  is less than ·30103.

The principal tables of Gaussian logarithms are (1) Matthiessen, *Tafel zur bequemern Berechnung* (Altona, 1818), giving  $B$  and  $C$  for argument  $A$  to 7 places, — this table is not so convenient one; (2) Peter Gray, *Tables and Formulas* (London, 1849), and *Addendum* (1870), giving full tables of  $C$  and  $\log(1-x)$  for argument  $A$  to 6 places; (3) Zach, *Tafeln der Additions- und Subtractions-logarithmen* (Leipzig, 1849), giving 7-place values of  $B$  for argument  $A$ , and 7-place values of  $C$  for argument  $B$ . These tables appeared originally in Hülse's edition of Vega's *Sammlung* (1849); (4)

Wittstein, *Logarithmes de Gauss* (Hanover, 1866), giving values of  $B$  for argument  $A$  to 7 places. This is a large table, and the arrangement is similar to that of an ordinary seven-figure table of logarithms.

In 1829 Widenbach published at Copenhagen a small table of modified Gaussian logarithms giving  $\log \frac{x+1}{x-1}$  ( $=D$ ) corresponding

to  $A$  as argument;  $A$  and  $D$  are thus reciprocal, the relation between them being in fact  $10^{A+D} = 10^A + 10^D + 1$ , so that either  $A$  or  $D$  may be regarded as the argument.

Gaussian logarithms are chiefly useful in the calculations connected with the solution of triangles in such a formula as  $\cot \frac{1}{2}C = \frac{a+b}{a-b} \tan \frac{1}{2}(A-B)$ , and in the calculation of life contingencies.

*Calculation of Logarithms.*—The name logarithm is derived from the words  $\lambda \acute{o} \gamma \omega \nu$  ἀριθμός, the number of the ratios, and the way of regarding a logarithm which justifies the name may be explained as follows. Suppose that the ratio of 10, or any other particular number, to 1 is compounded of a very great number of equal ratios, as for example 1,000,000, then it can be shown that the ratio of 2 to 1 is very nearly equal to a ratio compounded of 301,030 of these small ratios, or *ratinecula*, that the ratio of 3 to 1 is very nearly equal to a ratio compounded of 477,121 of them, and so on. The small ratio, or *ratinecula*, is in fact that of the millionth root of 10 to unity, and if we denote it by the ratio of  $a$  to 1, then the ratio of 2 to 1 will be nearly the same as that of  $a^{301,030}$  to 1, and so on; or, in other words, if  $a$  denotes the millionth root of 10, then 2 will be nearly equal to  $a^{301,030}$ , 3 will be nearly equal to  $a^{477,121}$ , and so on.

Napier's original work, the *Descriptio canonis* of 1614, contained, not logarithms of numbers, but logarithms of sines, and the relations between the sines and the logarithms were explained by the motions of points in lines, in a manner not unlike that afterwards employed by Newton in the method of fluxions. An account of the processes by which Napier constructed his table is given in the *Constructio canonis* of 1619. These methods apply, however, specially to Napier's own kind of logarithms, and are different from those actually used by Briggs in the construction of the tables in the *Arithmetica logarithmica*, although some of the latter are the same in principle as the processes described in an appendix to the *Constructio*. It may be observed that in the *Constructio* logarithms are called artificial, and this seems to have been the name first employed by Napier, but which he subsequently replaced by logarithms. It is to be presumed that he would have made the change of name also in the *Constructio*, had he lived to publish it himself.

The processes used by Briggs are explained by him in the preface to the *Arithmetica logarithmica* (1624). His method of finding the logarithms of the small primes, which consists in taking a great number of continued geometric means between unity and the given primes, may be described as follows. He first formed the table of numbers and their logarithms:

Number.	Logarithm.
10	1
3·162277 . . .	0·5
1·778279 . . .	0·25
1·333521 . . .	0·125
1·154781 . . .	0·0625

each quantity in the left hand column being the square root of the one above it, and each quantity in the right hand column being the half of the one above it. To construct this table Briggs, using about thirty places of decimals, extracted the square root of 10 fifty-four times, and thus found that the logarithm of 1·00000 00000 00000 12781 91493 20032 35 was 0·00000 00000 00000 05551 11512 31257 82702, and that for numbers of this form (i.e., for numbers beginning with 1 followed by fifteen ciphers, and

then by seventeen or a less number of significant figures) the logarithms were proportional to these significant figures. He then by means of a simple proportion deduced that  $\log(1.00000\ 00000\ 00000\ 1) = 0.00000\ 00000\ 00000\ 04342\ 91481\ 90325\ 1804$ , so that, a quantity  $1.00000\ 00000\ 00000\ x$  (where  $x$  consists of not more than seventeen figures) having been obtained by repeated extraction of the square root of a given number, the logarithm of  $1.00000\ 00000\ 00000\ x$  could then be found by multiplying  $x$  by  $.00000\ 00000\ 00000\ 04342\ 91481\ 90325\ 1804$ .

To find the logarithm of 2, Briggs raised it to the tenth power, viz., 1024, and extracted the square root of 1.024 forty-seven times, the result being 1.00000 00000 00000 16851 60570 53949 77. Multiplying the significant figures by 4342... he obtained the logarithm of this quantity, viz., 0.00000 00000 00000 07318 55936 90623 9336, which multiplied by  $2^{47}$  gave 0.01029 99566 39811 95265 277144, the logarithm of 1.024, true to 17 or 18 places. Adding the characteristic 3, and dividing by 10, he found (since 2 is the tenth root of 1024)  $\log 2 = .30102\ 99556\ 63981\ 195$ . Briggs calculated in a similar manner  $\log 6$ , and thence deduced  $\log 3$ .

It will be observed that in the first process the value of the modulus is in fact calculated from the formula

$$\frac{h}{10^k - 1} = \frac{1}{\log_{10} 10}$$

the value of  $h$  being  $\frac{1}{10^k}$ , and in the second process  $\log_{10} 2$  is in effect calculated from the formula

$$\log_{10} 2 = \left( \frac{10}{2^{47} - 1} \right) \cdot \frac{1}{\log_{10} 10} = \frac{2^{47}}{10}$$

Briggs also gave methods of forming the mean proportionals or square roots by differences; and the general method of constructing logarithmic tables by means of differences is due to him.

The following calculation of  $\log 5$  is given as an example of the application of a method of mean proportionals. The process consists in taking the geometric mean of numbers above and below 5, the object being to at length arrive at 5.000000. To every geometric mean in the column of numbers there corresponds the arithmetical mean in the column of logarithms. The numbers are denoted by  $A, B, C$ , &c., in order to indicate their mode of formation.

	Numbers.	Logarithms.
$A$	1.00000	0.0000000
$B$	10.0000000	1.0000000
$C$	$\sqrt{AB}$	3.162277
$D$	$\sqrt{BC}$	5.623413
$E$	$\sqrt{CD}$	4.216464
$F$	$\sqrt{DE}$	4.869674
$G$	$\sqrt{EF}$	5.232291
$H$	$\sqrt{FG}$	5.014965
$I$	$\sqrt{GH}$	4.958669
$K$	$\sqrt{HI}$	5.002865
$L$	$\sqrt{IK}$	4.989416
$M$	$\sqrt{KL}$	4.994627
$N$	$\sqrt{KM}$	4.997242
$O$	$\sqrt{KN}$	5.000052
$P$	$\sqrt{NO}$	4.998617
$Q$	$\sqrt{OP}$	4.999550
$R$	$\sqrt{OQ}$	4.999701
$S$	$\sqrt{OR}$	4.999876
$T$	$\sqrt{OS}$	4.999933
$U$	$\sqrt{OT}$	5.000009
$V$	$\sqrt{TV}$	4.999984
$X$	$\sqrt{UV}$	4.999997
$Y$	$\sqrt{VX}$	5.000005
$Z$	$\sqrt{XY}$	5.000000

Great attention was devoted to the methods of calculating logarithms during the 17th and 18th centuries. The earlier methods proposed were, like those of Briggs, purely arithmetical, and for a long time logarithms were regarded from the point of view indicated by their name, that is to say,

as depending on the theory of compounded ratios. The introduction of infinite series into mathematics effected a great change in the modes of calculation and the treatment of the subject. Besides Napier and Briggs, special reference should be made to Kepler (*Chilias*, 1624) and Mercator (*Logarithmotechnia*, 1668), whose methods were arithmetical, and to Newton, Gregory, Halley, and Cotes, who employed series. A full and valuable account of these methods is given in Hutton's "Construction of Logarithms," which occurs in the introduction to the early editions of his *Mathematical Tables*, and also forms tract 21 of his *Mathematical Tracts* (vol. i., 1812). Many of the early works on logarithms were reprinted in the *Scriptores logarithmici* of Baron Mascard (6 vols. 4to, 1791-1807).

In the following account only those formulae and methods will be referred to which would now be used in the calculation of logarithms.

Since

$$\log_e(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \&c.,$$

we have, by changing the sign of  $x$ ,

$$\log_e(1-x) = -x - \frac{1}{2}x^2 - \frac{1}{3}x^3 - \frac{1}{4}x^4 - \&c.;$$

whence

$$\log_e \frac{1+x}{1-x} = 2(x + \frac{1}{3}x^3 + \frac{1}{5}x^5 + \&c.),$$

and, therefore, replacing  $x$  by  $\frac{p-q}{p+q}$

$$\frac{p}{q} = 2 \left\{ \frac{p-q}{p+q} + \frac{1}{3} \left( \frac{p-q}{p+q} \right)^3 + \frac{1}{5} \left( \frac{p-q}{p+q} \right)^5 + \&c. \right\},$$

in which the series is always convergent, so that the formula affords a method of deducing the logarithm of one number from that of another.

As particular cases we have, by putting  $q=1$ ,

$$\log_e p = 2 \left\{ \frac{p-1}{p+1} + \frac{1}{3} \left( \frac{p-1}{p+1} \right)^3 + \frac{1}{5} \left( \frac{p-1}{p+1} \right)^5 + \&c. \right\}$$

and by putting  $q=p+1$ ,

$$\log_e(p+1) - \log_e p = 2 \left\{ \frac{1}{2p+1} + \frac{1}{3} (2p+1)^{-3} + \frac{1}{5} (2p+1)^{-5} + \&c. \right\}$$

the former of these equations gives a convergent series for  $\log_e p$ , and the latter a very convergent series by means of which the logarithm of any number may be deduced from the logarithm of the preceding number.

From the formula for  $\log_e \frac{p}{q}$  we may deduce the following very

convergent series for  $\log_e 2$ ,  $\log_e 3$ , and  $\log_e 5$ , viz.:

$$\log_e 2 = 2(7P + 5Q + 3R),$$

$$\log_e 3 = 2(11P + 8Q + 5R),$$

$$\log_e 5 = 2(16P + 12Q + 7R),$$

where

$$\frac{1}{31} = \frac{1}{(31)^3} + \frac{1}{(31)^5} + \&c.$$

$$\frac{1}{49} = \frac{1}{(49)^3} + \frac{1}{(49)^5} + \&c.$$

$$\frac{1}{161} = \frac{1}{(161)^3} + \frac{1}{(161)^5} + \&c.$$

The following still more convenient formulæ for the calculation of  $\log_e 2$ ,  $\log_e 3$ , &c. are given by Professor J. C. Adams in the *Proceedings of the Royal Society*, vol. xxvii. (1878), p. 91. If

$$\log \frac{10}{9} = -\log \left( 1 - \frac{1}{10} \right), \quad b = \log \frac{25}{24} = -\log \left( 1 - \frac{1}{100} \right),$$

$$\log \frac{81}{80} = -\log \left( 1 - \frac{1}{80} \right), \quad c = \log \frac{50}{49} = -\log \left( 1 - \frac{1}{50} \right),$$

$$e = \log \frac{126}{125} = -\log \left( 1 - \frac{1}{1000} \right),$$

then

$$\log 2 = 7a - 2b + 3c, \quad \log 3 = 11a - 3b + 5c, \quad \log 5 = 16a - 4b + 7c,$$

and

$$\log 7 = \frac{1}{2}(39a - 10b + 17c - d) \text{ or } -19a - 4b + 8c + e,$$

and we have the equation of condition,

$$a - 2b + c - d + 2e.$$

By means of these formulæ Professor Adams has calculated the values of  $\log_e 2$ ,  $\log_e 3$ ,  $\log_e 5$ , and  $\log_e 7$  to 260 places of decimals,

and he has deduced the value of  $\log_e 10$  and its reciprocal  $M$ , the modulus of the Briggsian system of logarithms. The value of the modulus found by Professor Adams is

M =	43429	44819	03251	82765	11289
	18916	60508	22943	97005	80366
	65661	14453	78316	58646	49208
	87077	47292	24949	33843	17483
	18706	10674	47663	03733	64167
	92871	58963	90656	92210	64662
	81228	58521	27086	56867	03295
	98370	86965	88265	88331	16360
	77384	90514	28443	48663	76864
	65860	85135	56148	21234	87653
	43543	43573	17247	48049	05993
	53353	05			

The values of the other logarithms are given in the paper referred to.

If the logarithms are Briggsian all the series in the preceding formulæ must be multiplied by  $M$ , the modulus; thus, for example,

$$\log_{10}(1+x) = M(x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \&c.),$$

and so on.

As has been stated, Abraham Sharp's table contains 61-decimal Briggsian logarithms of primes up to 1100, so that the logarithms of all composite numbers whose greatest prime factor does not exceed this number may be found by simple addition; and Wolfram's table gives 48-decimal hyperbolic logarithms of primes up to 10,009. By means of these tables and of a factor table we may very readily obtain the Briggsian logarithm of a number to 61 or a less number of places or of its hyperbolic logarithm to 48 or a less number of places in the following manner. Suppose the hyperbolic logarithm of the prime number 43,867 required. Multiplying by 50, we have  $50 \times 43,867 = 2,193,350$ , and on looking in Burekhardt's *Table des diviseurs* for a number near to this which shall have no prime factor greater than 10,009, it appears that

$$2,193,349 = 23 \times 47 \times 2029;$$

thus

$$43,867 = \frac{1}{50}(23 \times 47 \times 2029 + 1),$$

and therefore

$$\log_e 43,867 = \log_e 23 + \log_e 47 + \log_e 2029 - \log_e 50 + \frac{1}{2,193,349} - \frac{1}{2(2,193,349)^2} + \frac{1}{3(2,193,349)^3} - \&c.$$

The first term of the series in the second line is

$$0.00000 \quad 04559 \quad 23795 \quad 07319 \quad 6286;$$

dividing this by  $2 \times 2,193,349$  we obtain

$$0.00000 \quad 00000 \quad 00103 \quad 93325 \quad 3457,$$

and the third term is

$$0.00000 \quad 00000 \quad 00000 \quad 00003 \quad 1590,$$

so that the series—

$$0.00000 \quad 04559 \quad 23691 \quad 13997 \quad 4419;$$

whence, taking out the logarithms from Wolfram's table,

$$\log_e 43,867 = 10.68891 \quad 76079 \quad 60568 \quad 10191 \quad 3661.$$

The principle of the method is to multiply the given prime (supposed to consist of 1, 5, or 6 figures) by such a factor that the product may be a number within the range of the factor tables, and such that, when it is increased by 1 or 2, the prime factors may all be within the range of the logarithmic tables. The logarithm is then obtained by use of the formula

$$\log_e(x+d) = \log_e x + \frac{d}{x} - \frac{1}{2} \frac{d^2}{x^2} + \frac{1}{3} \frac{d^3}{x^3} - \&c.,$$

in which of course the object is to render  $\frac{d}{x}$  as small as possible.

If the logarithm required is Briggsian, the value of the series is to be multiplied by  $M$ .

If the number is incommensurable or consists of more than seven figures, we can take the first seven figures of it (or multiply and divide the result by any factor, and take the first seven figures of the result) and proceed as before. An application to the hyperbolic logarithm of  $\pi$  is given by Burekhardt in the introduction to his *Table des diviseurs* for the second million.

The best general method of calculating logarithms consists, in its simplest form, in resolving the number whose logarithm is required into factors of the form  $1 \pm 1^n$ , where  $n$  is one of the nine digits, and making use of subsidiary tables of logarithms of factors of this form. For example, suppose the logarithm of 543839 required to twelve places. Dividing by  $10^5$  and by 5 the number becomes 1.087678, and resolving this number into factors of the form  $1 \pm 1^n$  we find that

$$543839 = 10^5 \times 5(1 - 1^{18})(1 - 1^{16})(1 - 1^{16})(1 - 1^{13})(1 - 1^{13}) \times (1 - 1^{15})(1 - 1^{17})(1 - 1^{19})(1 - 1^{13})(1 - 1^{12})$$

where  $1 - 1^{18}$  denotes  $1 - .08$   $1 - 1^{16}$  denotes  $1 - .0006$ , &c., and so

n. All that is required therefore in order to obtain the logarithm of any number is a table of logarithms, to the required number of places, of  $1^n$ ,  $9^n$ ,  $99^n$ ,  $999^n$ , &c., for  $n=1, 2, 3, \dots 9$ .

The resolution of a number into factors of the above form is easily performed. Taking, for example, the number 1.087678, the object is to destroy the significant figure 8 in the second place of decimals; this is effected by multiplying the number by  $1 - .08$ , that is, by subtracting from the number eight times itself advanced two places, and we thus obtain 1.00066376. To destroy the first 6 multiplied by  $1 - .0006$  giving 1.000063361744, and multiplying successively by  $1 - .00006$  and  $1 - .000003$ , we obtain 1.000000357932, and it is clear that these last six significant figures represent without any further work the remaining factors required. In the corresponding antilogarithmic process the number is expressed as a product of factors of the form  $1 \pm 1^n$ .

This method of calculating logarithms by the resolution of numbers into factors of the form  $1 \pm 1^n$  is generally known as Weddle's method, having been published by him in *The Mathematician* for November 1845, and the corresponding method for antilogarithms by means of factors of the form  $1 \pm (1/n)^n$  is known by the name of Heann, who published it in the same journal for 1847. In 1846 Mr Peter Gray constructed a new table to 12 places, in which the factors were of the form  $1 \pm (1/n)^n$ , so that  $n$  had the values 1, 2, 3, ..., 39; and subsequently he constructed a similar table for factors of the form  $1 \pm (1/n)^n$ . He also discovered a method of applying a table of Heann's form to factors of the form  $1 \pm 1^n$  to the construction of logarithms, and calculated a table of logarithms of factors of the form  $1 \pm (1/n)^n$  to 24 places. This was published in 1876 under the title *Tables for the formation of logarithms and antilogarithms to ten, eleven or any less number of places*, and contains the most complete and useful application of the method, with many improvements in points of detail. Taking as an example the calculation of the Briggsian logarithm of the number 43,867, whose hyperbolic logarithm has been calculated above, we multiply it by 3, giving 131,601, and find by Mr Gray's process that the factors of 131,601 are

(1) 1.316	(5) 1.00175002
(2) 1.0000007	(6) 1.00178602
(3) 1.0017598	(7) 1.0017412
(4) 1.001780	(8) 1.001740

Taking the logarithms from Mr Gray's tables we obtain the required logarithm by addition as follows:—

522	878	745	280	337	562	704	972	$\log 3$
119	255	889	277	936	685	553	913	$\log (1)$
		3	040	056	733	157	610	$\log 2$
		259	708	022	525	153	587	$\log (3)$
			338	719	695	752	421	$\log (4)$
					868	588	961	$\log (5)$
					261	115	258	$\log (6)$
						178	929	
							118	

$$136 \quad 031 \quad 655 \quad 780 \quad 757 \quad 288 \quad 464 \quad \log_{10} 43,867$$

In Shortrede's *Tables* there are tables of logarithms and factors of the form  $1 \pm (1/n)^n$  to 16 places and of the form  $1 \pm (1/n)^n$  to 25 places; and in his *Tables de logarithmes* of 27 Dec-1865 (Paris, 1867) Fehér Thoman gives tables of logarithms of factors of the form  $1 \pm 1^n$ . In the *Messenger of Mathematics*, vol. ii, pp. 66-92, 1873, Mr Henry Wace gave a simple and clear account of both the logarithmic and antilogarithmic processes, with tables of both Briggsian and hyperbolic logarithms of factors of the form  $1 \pm 1^n$  to 20 places.

Although the method is usually known by the names of Weddle and Heann, it is really, in its essential features, due to Briggs, who gave in the *Arithmetica logarithmica* of 1624 a table of the logarithms of  $1 \pm 1^n$  up to 9 to 15 places of decimal. It was first formally proposed as an independent method, with great improvements, by Robert Flower in *The Recluse, a new way of making Logarithms*, which was published in 1771; and Leonelli, in his *Supplément logarithmique* (1802-3), already noticed, referred to Flower and reproduced some of his tables. A complete bibliography of this method has been given by Mr A. J. Ellis in a paper "on the potential index as a means of calculating logarithms," printed in the *Proceedings of the Royal Society*, vol. xxvi, 1881, pp. 401-407, and vol. xxxii, 1881, pp. 377-379. Reference should also be made to Hopp's *Tabulae der dreissigstelligen logarithmischen Rechnung* (Leipzig, 1876), which give in a somewhat modified form a table of the hyperbolic logarithm of  $1 \pm 1^n$ .

The preceding methods are only appropriate for the calculation of isolated logarithms. If a complete table had to be reconstructed, or calculated to more places, it would undoubtedly be most convenient to employ the method of differences. A full account of this method as applied to the calculation of the *Tables du Cadastre* is given by M. Lefort in vol. iv. of the *Annales de l'Observatoire de Paris*. (J. W. L.-43.)

## LOGIC

1. LOGIC, in the most general acceptance of the term, may be regarded as the systematic study of thought. So wide a definition is certainly sufficient to comprehend all that may have been at various times included within the scope of logical doctrine, but in other respects it is of small value. It does not serve to mark off logic from philosophy as a whole, which is unquestionably the systematic exposition of thought, nor from psychology, which includes within its wider range what may well be described as the study of thought. Without some more accurate discrimination of the province and method of logic, neither the extent of matter to be included within the study nor the peculiarity of the method by which such matter is treated can be determined.

Preliminary queries of a similar kind are naturally encountered in the case of all other branches of human knowledge, and are generally answered by two methods. We may refer either to the distinct characteristics of the matter to be treated, or to the essential features of the method of treatment. We may determine the province of a science either by external division, by classification of objects according to their prevailing resemblances and differences, or by internal definition, by exposition of the fundamental characters of the method employed. By neither process, unfortunately, can an unambiguous answer be supplied, at least without much art, in the case of logic.

2. The reasons for the manifold difficulties encountered in the attempt to determine accurately the province of logic, whether by reference to a division of the sciences or by precise definition of the essential features of logical analysis, are not far to seek. The systematic classification of the sciences involves not only consideration of the contents of the sciences as empirically presented, but also certain leading principles or fundamental views, which are an essence of a philosophical character. According to the general conception of knowledge which in various kinds is manifested in the special sciences, there will be radically divergent methods of classification, and the province assigned to each member of the ensemble will, for the most part, have its limits determined according to the character of the general view adopted. Moreover, if any of the more prominent specimens of classification of the sciences be critically inspected, they will be found to presuppose a certain body of principles, of scope wider than any of the special disciplines, and to which no place in the ensemble can be assigned. In short, a systematic distribution of human knowledge into its distinctly marked varieties rests upon and presupposes a general philosophy, the character of which affects the place and function of each part of the distribution. Logic, as may readily be imagined, has therefore experienced a variety of treatment at the hands of systematizers of scientific knowledge. It has appeared as one of the abstract sciences, in opposition to those disciplines in which the character of the concrete material is the essential fact; as a subordinate branch of a particular concrete science, the investigation of mental phenomena; as a nondescript receptacle for the formulation in generalized fashion of the method and logical precepts exemplified in the special sciences. By such processes no more has been effected than to bring into light, more or less clearly, some of the characteristics of the supposed science, without in any way supplying an exhaustive and comprehensive survey of its boundaries and relations to other branches of knowledge. Thus, when logic is marked off from the concrete sciences and associated with mathematics in the most general sense, as the treatment

of formal relations,<sup>1</sup> and further differentiated from mathematics as implying no reference to the quantitative character of the most general relations under which facts of experience present themselves,<sup>2</sup> there is certainly brought to the front what one would willingly allow to be a commonplace respecting all logical analysis, namely, that its principles are coextensive with human knowledge, and that all objects as matters of conscious experience have an aspect in which they are susceptible of logical treatment. But no more is effected. It is still left to a wider consideration to determine what the specific aspect of things may be which shall be called the *formal* and be recognized as the peculiarly logical element in them. There may be selected for this purpose either the general relations of coincidence and succession in space and time, or the fundamental properties of identity and difference, or the existences of classes, but in any case such selection depends upon and refers to a theory of the nature of knowledge and of the constitution of things as known. In truth, the notions of *form* and *formal relations* are by no means so simple and free from ambiguity that by their aid one can at once solve a complicated problem of philosophic arrangement. To lay stress upon *form* as the special object of logical treatment still leaves undecided the nature and ground of the principles which are to be employed in evolving a science of form, and therefore leaves the logical problem untouched.

Still less satisfactory are the results when logic is regarded as in some way a subordinate branch of the psychological analysis of mental phenomena.<sup>3</sup> Neither the grounds on which such a classification rests, nor the conclusions deduced from it, seem beyond criticism. The simple facts that certain mental processes are analysed in logic, and that psychology is generally the treatment of all mental processes, by no means necessitate the view that logic is therefore the outgrowth from and a subordinate part of psychology. For it is clear, on the one hand, that logic has a scope wider than psychology, since in any sense of the term it has to deal with all the processes (or with some aspect of all the processes) by which on any subject knowledge is formed out of disjointed or disconnected experiences. And, on the other hand, since the subordination of one science to another, as species to genus, is fallacious, unless the two agree in fundamental characteristics, the position so assigned to logic would imply that in aim and method it shall be essentially one with psychology, a position equivalent to the negation of logic as a separate and independent discipline. It is not surprising therefore to find that so soon as logic has been distinguished as arising from psychology, and so dependent on it, the peculiarity of its position and functions compels the recognition of its more general scope and the reduction of its connexion with psychology to an amount small enough to be compatible with absolute independence. Strong

<sup>1</sup> As, e.g., by H. Spencer, *Classification of the Sciences*, pp. 6, 12; H. Grassmann, *Die Ausdehnungslehre von 1844* (1878), Einleitung, xxii.-xxiii.

<sup>2</sup> Logic and mathematics, under this view, may be regarded either as generically distinct—which is apparently the opinion of Spencer, H. Grassmann, and Jevons—or as species of a more comprehensive genus, the theory of formal (symbolic) operations—which is apparently the opinion of R. Grassmann (see his *Formenlehre*, 1872) and Boole (see his *Mathematical Analysis of Logic*, 1847, p. 1, and *Differential Equations*, 1859, chap. xvi., especially pp. 388-389). An admirable treatment of that which is implied in Boole's method is given in Mr Veatch's *Symbolic Logic*, 1881.

<sup>3</sup> For this extremely common arrangement, see Hamilton, *Lectures on Metaphysics*, i. p. 121-3; Ueberweg, *System der Logik*, § 6.

reasons, indeed, may be advanced for holding that logic is entirely to be separated from psychology, as differing from it in aim, method, and principle, that logical analysis is generically distinct from psychological, and that the two disciplines, while connected as parts of the general body of philosophical reflexion, hold to one another a relation the reverse of that commonly accepted.<sup>1</sup>

As to the endeavour to collect from consideration of the sciences in detail a body of precepts, the rules of scientific method, and to assign the systematic arrangement of such rules to one special discipline, called logic, it seems to stand on the same footing and to be open to the same criticism as the allied attempt to treat general philosophy as the receptacle for the most abstract propositions reached in scientific knowledge. There is a peculiar assumption underlying the supposed possibility of distinguishing between scientific method and its concrete exemplifications in the special sciences, and only on the ground of this assumption could there be rested the independence of logic as the systematic treatment of method. It is taken for granted, without examination, that the characteristic features of correct and well-founded thinking are palpable and general, and that we thus possess a criterion for marking off what is common to all scientific procedure from that which is special and peculiar to the individual sciences. An elaborate philosophic doctrine lies at the root of this assumption, and the position assigned to logic may easily be seen to depend, not on what is apparent in the argument, namely, comparison of the sciences with one another, but on what lies implicit in the background, the philosophic conception of the nature of scientific knowledge in general. Without reference to the ultimate philosophic view, no definite content could be assigned to logic, and it would remain impossible to distinguish logic from the sciences in detail.<sup>2</sup>

3. Thus the various attempts to define the province and functions of logic from general classification of the sciences, to define, in short, by the method of division, yield no satisfactory answer, and refer ultimately to the philosophic view on which classification and division must be based. A similar result becomes apparent when we consider the various descriptions of logic that have been presented as following from more precise and accurate determination of the essential features of logical analysis and method.

"The philosophical deduction or construction of the notion of logic presupposes a comprehensive and well-grounded view, whether of the nature and mode of operation of the human mind, a definite part of which falls under logical treatment, or of the problems and objects of philosophy in general, from among which in due order may be distinguished the particular problem of logic."<sup>3</sup> The most elementary distinctions, by means of which, in the ordinary exposition of logic, progress is effected towards an accurate determination of the province of the science, not only refer to some such ultimate philosophic view, but lead to the most diverse results, according to the peculiarity of the views on which they are based. Of these elementary distinctions the following are at once the more usual and the more important:—the distinction between the province of logic and the province of the special sciences, as that between general and special; the distinction between

natural growth of knowledge, with its natural laws, and the normal procedure whereby grounded knowledge is obtained, with its normal or regulative principles; the distinction between knowledge as a whole and its several parts, immediate and mediate, with restriction of logic to the treatment of all or portion of mediate knowledge; the distinction between the constituents of knowledge as on the one hand given from without (in experience), and on the other hand due to the elaborative action of intellect itself. To one or other of these may be traced the common definitions of logic, and a brief consideration of their contents will be sufficient to show that they severally rest upon more or less developed general philosophic doctrines, and that their significance for accurate determination of the field of logic depends not so much on what is explicitly stated in them as on what is implied in the general doctrines from which they have taken their rise.

The distinction of logic from the sciences, as dealing in the abstract with that which is concretely exemplified in each of them, is certainly a first step in the process of determination about which there can be little or no doubt. But if the distinction remain vague, it is not sufficient to differentiate logic from many other disciplines, philosophical or philological, and if it be made more precise, the new characteristics will be found to involve some special view as to what constitutes the common feature in the sciences, and to vary with the possible varieties of view. As a rule, too, the added characteristics do not serve by themselves to mark off logical treatment as an independent kind of investigation. They are most frequently obtained by a general survey of scientific procedure. Thus it may be said that in all sciences there are implied clearly defined notions, general statements or judgments, and methodical proofs; logic therefore, as the theory of the general element in science, will appear as the treatment of notions, judgments, and proofs generally, or in the abstract. If so, then, unless some implied principle further determine the course of procedure, logic would be regarded as a merely descriptive account of the parts making up scientific knowledge, and it would be not only impossible to assign to it an independent position, but hard to discriminate it from psychology, which likewise deals with the parts of knowledge. If it be understood, however, or explicitly stated, that in all scientific knowledge there is community of method, resting on common principles or laws of knowledge as such, then clearly not only the province of logic, as now made identical with the treatment of the essence of knowledge, but the special nature of the theorems making up the body of logic, must depend upon the general conception of knowledge with which the thinker starts. In the view of logic taken, e.g., by Mill, the fundamental idea is that of *evidence*, under which must be included all the grounds for any judgment not resting on immediate perception. So far as verbal statement is concerned, the adoption of this as the root idea would not distinguish in any special way the treatment of logical problems resting on it, but in fact each problem is dealt with in accordance with the particular theory of what, from the nature of human knowledge, constitutes evidence. Logic thus involves, or in truth becomes, a theory of knowledge, and in the end, for general spirit and details of doctrine, refers to an ultimate philosophic view. There seems no escape from this conclusion. Start as we may, with popular, current distinctions, no sooner do logical problems present themselves than it becomes apparent that, for adequate treatment of them, reference to the principles of ultimate philosophy is requisite, and logic, as the systematic handling of such problems, ceases to be an independent discipline, and becomes a subordinate special branch of general philosophy.

The attempt to avoid this conclusion must of necessity

<sup>1</sup> It is to be acknowledged that most of the writers on logic who emphasize the connexion of psychology with logic introduce distinctions equivalent to the remarks above made, but the grounds for such distinctions and the confusions to be deduced from them are not generally brought into clear light.

<sup>2</sup> See, for a clear statement of this impossibility, Comte, *Philos. Positive*, i. 34, 35. Definitions of logic as theory of method, which are based on general philosophic views (e.g., the definition by Sigwart, *Logic*, i. § 1), stand on a different footing, and are to be examined on different principles.

<sup>3</sup> Twesten, *Die Logik, insbesondere die Analytik* (1825), p. 2.

take form in some discrimination of logic from other varieties which may with it be classed under philosophy in general, and such discrimination is usually effected by laying stress on one or other of the following characteristics.

(1) In the whole process of knowledge, it may be said, we are able to distinguish and to regard in isolation the methods according to which, from a combination of various elements, cognition of things grows up, and the laws according to which these elements must be ordered, if our subjective consciousness is to represent accurately and faithfully the relations of things. The laws of knowledge, there being understood by knowledge the whole sum of mental determinations in and through which the world of external and internal experience is realized for us, are of two distinct kinds, natural and normal. For the treatment of the natural laws the most appropriate title is psychology; for that of the normal or regulative laws the title logic is peculiarly appropriate. By the one science knowledge is regarded in its relation to the subjective consciousness, as so much of what enters into and constitutes the world of inner experience; by the other knowledge is regarded in its relation to truth, to the objective system, as the means whereby, for theoretical or practical purposes, an orderly and verifiable conception of this system is realized. A definite place seems thus secured for logic, but, if one may judge merely from the various attempts to expound the body of logical doctrines from this point of view, the characteristic feature is not yet sufficient to determine the boundaries of the science or the specific nature of its problems. In fact, the feature selected might be accepted as the distinguishing mark of logical science by writers who would include under that common title the most diverse matters, and who would differ fundamentally in respect to the treatment of isolated problems. The metaphysical logic of Hegel, the empirical logic of Mill, the formal logic of Kant, might all claim to be developments of this one view of the essence of logic. So wide a divergence is clear evidence that the criterion selected, though possibly accurate, is not sufficiently specific, and that the interpretation of it, which in truth determines for each the nature and boundaries of the science, depends upon the view taken respecting knowledge as a whole in its relation to the objective order of experience, respecting the import of the so-called normal laws, and respecting the subjective elements supposed to constitute knowledge.

On all sides this particular definition of logic is beset with difficulties, which it cannot afford to dismiss by means of the simple demand that knowledge shall be accepted as somehow given. For, apart altogether from the danger that under so wide a term as knowledge many differences may be accommodated, it then becomes impossible to do more than treat in a quasi-empirical fashion mental facts, the nature and peculiarities of which are to be learned from some external source. In the later, more detailed examination of the view of logic here briefly described, it will be pointed out that the usual formula by which the several logical notions are introduced, viz., that their nature as mental facts is dealt with in psychology, from which logic borrows, is in fact much more than a formula. The logical peculiarities will be found to rest mainly upon the psychological characteristics as borrowed, while it is evident that no substantive, independent existence can be vindicated for a doctrine, the succession of whose parts, and their essential nature, are given externally.

(2) Some of the perplexities that arise when logic is treated as the theory of the normal laws of knowledge may be obviated by the current distinction between immediate and mediate knowledge. The normal laws of knowledge might be said to apply solely to the process of mediate cognition, and their final aim would be defined as harmony

between mediate knowledge and immediate experience. But it is difficult to distinguish with perfect accuracy between the two kinds of knowledge in question; it is impossible that the treatment of the logical problem should not depend entirely on the view taken as to the nature of that which differentiates mediate from immediate knowledge. Whether we express this as thought or as belief, its nature then becomes the all-important factor in determining the course of logical treatment, and further progress will manifest divergencies according as stress is laid on the subjective characteristics of thought, the laws to which, from its essential nature, all its products must conform, or on the limitations imposed by principles which have reference to the most general relations of the things thought about. In the one case a formal logic, of the type commonly known as the Kantian, would be developed, in the other either an empirical logic, like that of Mill, wherein the nature of notions, propositions, and reasonings is considered from the point of view of the empirical conception of experience, or a transcendental logic, like that involved in the *Critique of Pure Reason*, or a metaphysical logic, like that of Hegel, or a mixed doctrine, like that of Trendelenburg, Lotze, and Ueberweg. In short, the general philosophic view of thought is that upon which the character of logic as a science rests.

(3) There has above appeared, incidentally, one of the most current methods of solving the logical problem, by procedure from the distinction between that which is given to the mind in knowledge, and that which is supplied by the mind itself. No distinction seems more simple; none is in reality more complex. The opposition on which, in its popular acceptance, it rests is that between the individual concrete thinking subject and the world of objective facts, existing, as it were, to be cognized. The full significance of such an opposition, the forms in which it presents itself in conscious experience, the qualifications which must be introduced into the statement of it that it may have even a semblance of reality,—these are problems not solved by a simple reference to the distinction as existing. It may well be held that knowledge is, for the individual, the mode (or one of the modes) in which his relation to the universe of fact is subjectively seized, but it is not therefore rendered possible to effect an accurate and mechanical separation of knowledge into its matter and form. Even on lower grounds it may be held that by the employment of this criterion little or no light is thrown upon the logical question. For no determination is supplied by it of the universal characteristic of form as opposed to matter in knowledge, and a comparison of various expositions will show the most startling diversity of view respecting the nature and boundaries of the formal element in knowledge. It is of course true that in one sense any scientific treatment of knowledge is formal. Our analysis extends only to the general or abstract aspect of cognition, not to its actual details. But we are not, on that account, dealing with the form of knowledge. So soon as it is attempted to define more accurately what shall be understood by form then it is found that various views of logic arise, corresponding to the variety of principles supposed to be applied in the treatment of form. Thus the stricter followers of the Kantian logical idea, e.g., Mansel and Spalding, recognize, as sole principles which can be said to be involved universally in the action of thought, the laws of identity, non-contradiction, and excluded middle, and in their hands logic becomes merely the systematic statement of these laws, and the exposition of the conditions which they impose upon notions, judgments, and reasonings. Analytical consistency, i.e., absence of contradiction, is on this view the one aspect of knowledge which is susceptible of logical treatment. On the other hand, the idea of a contribution furnished by the

mind itself to knowledge may lead to a more concrete and yet not less exact system of the forms of knowledge, if there be taken into account the real character of the operation, by which such contribution is made. Thus in the logic of Ulrici, from the view of thought as essentially the distinguishing faculty, by which definiteness is given to the elements entering into knowledge, there follows not simply an iteration of the principle that thought must not contradict itself, but a systematic evolution of the fundamental relations involved in the action of thought, in which the more specifically logical products, the notion, judgment, and reasoning, have a determinate place assigned to them.

Not only, then, may quite distinct provinces be assigned to logic by thinkers who start with the same idea of thought as contributing to knowledge, but, as may well be imagined, the treatment of special logical problems presents a most bewildering variety. The nature of judgment, the principle of reasoning, the characteristics of thought which is in accordance with logical rule, will be viewed differently according to the special interpretation put upon the functions of the subjective factor in knowledge. Here again we find that the really influential fact in the determination of the province and method of logical science is a general philosophic conception of knowledge or thought.<sup>1</sup>

4. There remains yet one method by which a clear and sufficient definition of the province and function of logic may be attainable. It may be that the separation of logic from other philosophic disciplines has come about historically, and that the assignment to logic of a special body of problems and a special kind of treatment is due to the accidents of its development. We might therefore hope to gain from a comparative survey of the field of logic, as that has been historically marked out, some definite view not only respecting the specific problems of logical theory, but also regarding the grounds for the isolated treatment of them. That in the history of logic there should be found a certain continuity of doctrine and development may, however, be compatible with entire absence of a common body of received logical matter, and the result of an historical research may be little more than a statement of distinct conceptions regarding the nature and province of the science, leading to the inclusion of very distinct materials within its scope. It requires but a superficial investigation of that which at various intervals has presented itself as logical theory to arrive at the conclusion that the differences in general spirit and in the mass of details far outbalance any agreement as to a few detached doctrines and technical symbols. If the survey were limited even to the period preceding the attempts at radical reformation of philosophy in general, and of logic as included therein, to the period in which the Aristotelian doctrines, as they may be called, formed the common basis of logical treatment, we should be able to detect differences of such a kind as to indicate radically distinct fundamental views. The scholastic logic, which, even by itself, cannot be regarded as one theory with unimportant modifications, is most falsely described as Aristotelian. The technical terminology, the general idea and plan, and some of the formal details are certainly due to the Aristotelian analysis of reasoned knowledge, but in spirit, in ruling principles, and in the mass of details the method of the scholastic logic is alien to that of Aristotle. It will be shown later that the Aristotelian analysis is saturated with the notions and aims of the Aristotelian metaphysics and general theory of knowledge, and that on this account alone, apart from

the introduction of many foreign ingredients, from Stoic, Arab, and Byzantine sources, into the scholastic system, an important difference must subsist between the original doctrine and that which presents itself as but its historical development. Even more radical is the divergence of modern logic from the Aristotelian ideal and method. The thinker who claimed for logic a special pre-eminence among sciences because "since Aristotle it has not had to retrace a single step, . . . and to the present day has not been able to make one step in advance,"<sup>2</sup> has himself, in his general modification of all philosophy, placed logic on so new a basis that the only point of connexion retained by it in his system with the Aristotelian may be not unfairly described as the community of subject. Both deal in some way with the principles and methods of human thinking, but as their general views of the constitution of thought are diverse, little agreement is to be found in the special treatment of its logical aspect. So when a later writer prefaces his examination of logical principles with the declaration that "logic is common ground on which the partisans of Hartley and of Reid, of Locke and of Kant, may meet and join hands,"<sup>3</sup> we are not unprepared for the result that, with a few unimportant exceptions, his views of logical principle coincide with those of no recognized predecessor in the same field, diverge widely from either the currently received or the genuine Aristotelian doctrines, and lead to a totally new distribution, in mass and detail, of the body of logical theorems and discussions. Such divergence is, indeed, most intelligible. If one reflects on the significance which would be attached in any one of these logical systems, of Aristotle, of Kant, of Mill, to the *universal* or universalizing element of thought, and on the fact that such universal must manifest itself as the characteristic feature in all the important products of thinking, the notion, the judgment, the syllogism, the conclusion is inevitable that difference of view in respect to the essence must make itself felt in difference of treatment of details. The ultimate aim of proof, and the general nature of the methods of proof, must appear differently according as the accepted ground is the Aristotelian conception of nature and thought, the Kantian theory of cognition, or subject-empiricism.

If, adopting a simpler method, one were to respect a fair proportion of the more extensive recent works on logic, the conclusion drawn would be probably the same. That, while the matters treated show a slight similarity, no more than could naturally result from the fact that thought is the subject analysed, the diversity in mode of treatment is so great that it would be impossible to select by comparison and criticism a certain body of theorems and methods, and assign to them the title of logic. That such works as those of Trendelenburg, Ueberweg, Ulrici, Lotze, Sigwart, Wundt, Bergmann, Schuppe, De Morgan, Boole, Jevons, and these are but a selection from the most recent, treat of notions, judgments, and methods of reasoning, gives to them indeed a certain common character, but what other feature do they possess in common? In tone, in method, in aim, in fundamental principles, in extent of field, they diverge so widely as to appear, not so many different expositions of the same science, but so many different sciences. In short, looking to the chaotic state of logical text-books at the present time, one would be inclined to say that there does not exist anywhere a recognized, currently received body of speculations to which the title logic can be unambiguously assigned, and that we must therefore resign the hope of attaining by any empirical consideration of the received doctrine a precise determination of the nature and limits of logical theory.

<sup>1</sup> In Rosenkranz, *Die Modificationen der Logik abgeleitet aus dem Begriff des Denkens* (1846), a similar conclusion is illustrated by an elaborate classification of possible modifications of the view of logic. Compare also Bruns, *Die Logik in ihrem Verhältniss zur Philosophie geschichtlich betrachtet* (1828).

Kant, *Kritik der reinen Vernunft*, p. 13.  
Mill, *System of Logic*, i. p. 1.

5. In order to make clear the reasons for this astonishing diversity of opinion regarding the province and method of logic, and so make some advance towards a solution of what may well be called the logical problem, it seems necessary to consider some of the leading conceptions of logic, with such reference to details as will suffice to show how difference of fundamental view determines the treatment of special logical problems. In this consideration the order must be historical rather than systematic. Not, indeed, that it is needful, nor is it proposed, to present an historical account of philosophy at large, or even of logic in particular; our purpose is merely to disentangle and bring clearly forward the nature of the principles respecting logical theory which have served as basis for the most characteristic logical systems. Such an inquiry will not only assist in explaining the divergencies of logical systems, but throw light upon the essence of logic itself.<sup>1</sup>

In this historico-critical survey, the first section must naturally be devoted to a consideration of the Aristotelian logic. The records of Oriental attempts at analysis of the procedure of thought may, for our present purpose, be disregarded.<sup>2</sup>

#### *The Aristotelian Logic.*

6. In a remarkable passage at the close of the tract called by us the *Sophistical Refutations*, Aristotle claims for himself distinct originality in the conception of subjecting to analysis the forms or types of argument. "The system I have expounded had not been partially, though imperfectly, elaborated by others; its very foundations had to be laid. . . . The teachers of rhetoric inherited many principles that had long been ascertained; dialectic had absolutely no traditional doctrines. Our researches were long, tentative, and troublesome. If, then, starting from nothing, it bears a comparison with others that have been developed by division of labour in successive generations, candid criticism will be readier to commend it for the degree of completeness to which it has attained than to find fault with it for falling short of perfection."<sup>3</sup> Although the specific reference in this passage is to the analysis of dialectical argument contained in the *Topica*, the same claim might with justice have been made in regard to the more extensive analysis of the forms of reasoning in general which makes up the substance of the other books of the *Organon*. There had been, prior to Aristotle, much discussion of problems that would under any view be included under the head of logic, but no systematic attempt had been made to analyse knowledge as a whole in its formal aspect, to throw under general heads or classes the types of reasoning, whether dialectical or scientific, and to exhibit the general relations in which the elements of all reasoning stand to one another. After Aristotle, it became possible to refer all such discussions to a common head, and to view them as component parts of one systematic doctrine. In a peculiar sense, then, Aristotle may be described as the founder of logical science.

The precise nature of the inquiries falling within the scope of the Aristotelian logic may receive some preliminary explanation supplementary to that which can only be given by a careful study of the chief theorems of the system, if there be taken into account (a) the advances towards a theory of logical method contained in the speculations of earlier Greek thinkers, (b) the classification of philosophic discipline which underlies the body of Aristotle's writings, and (c) the general conception of the matter of logical analysis which may be deduced from any special or incidental treatment of the question in Aristotle. Of these in order.

#### 7. (a) Logical discussions prior to Aristotle.

The inquiries which find a place in the Aristotelian logic are all, in a large sense, problems of the theory of knowledge. They arise, therefore, only in connexion with critical reflexion on the nature, grounds, and method of knowledge. The earliest forms of Greek speculation, turning rather upon explanation of natural fact, being in essence attempts to reduce the multiplicity of known fact to unity of principle, contain, as a consequence, problems of a metaphysical character, which might involve problems of strictly logical character, but were logical only in potentiality. Of all these metaphysical questions the most important centre round the fundamental opposition between unity of principle and multiplicity of fact, between the one and the many, an opposition which under varied forms presents itself at every stage in the

history of philosophic speculation. In the first period of Greek speculation, the problem presented itself in its simplest, most direct aspect, and, after a few rough attempts at a quasi-physical explanation of the genesis of many out of one, there came forward, as reasoned, ultimate solutions, the Eleatic doctrine that only unity has real being, the Heraclitic counter-doctrine that only in change, in the many, is truth to be found, and the Pythagorean notion of number, harmony, as containing in abstracto the union of the opposites, one and many. No one of these philosophic treatments can be said to contain specifically logical elements, but they raise questions of a logical kind, and, especially in the records of the Eleatic views, one can trace a close approximation to the critical reflexion which marks the transition to a new order of ideas. Results which in these systems are stated with metaphysical reference only, reappear with new aspect among the sophists and the Socratic schools. The transition stage, indeed, partly aided by the atomic separation of objective fact from subjective sense experience, is mainly the effect of the sophistic and Socratic teaching. Socrates and the sophists have this in common that both treat the fundamental problem of philosophy as it had been handed down with special reference to the subjective experience of the individual. In the teaching of the sophists generally is to be discerned the opposition between subjective reflexion and objective fact; in that of Protagoras and Gorgias in particular there appear as problems of the theory of knowledge difficulties for the older metaphysics of Heraclitus and the Eleatics respectively. The Heraclitic principle of change is the general foundation for the doctrine that the momentary perception is the only fact of cognition, and upon it may be based the conclusions that all truth is relative to the individual state of the individual subject, and that judgment, as a mode of expressing truth, is a contradiction in itself. Thus the extreme Heracliteans, as Cratylus, rejected the proposition, or combination of words, as expressing a unity and permanence not to be found in things, and reduced speech to the symbolism of pointing with the finger. Less developed but not less clear is the connexion between the brief sceptical theses of Gorgias and the Eleatic doctrine of unity. As knowledge was impossible on the Heraclitean view, since it implied a synthesis not discoverable amidst incessant change, so for Gorgias knowledge was impossible, since in the synthesis was involved an element of difference, multiplicity, not reconcilable with the all-embracing unity of things. It is evident from the treatment of such views in Plato and in Aristotle, how many of the illustrations used in support of the general thesis depended for their apparent strength on neglect of some of the elementary conditions of thought, and how inevitably reflexion upon these difficulties led to the construction of a theory of thought. The first outlines of such a theory are to be found in the Socratic principle of the notion (or concept, as we may call it, for the notion as viewed by Socrates is certainly the concrete class notion, the simple result of generalization and abstraction), and to Socrates is assigned by Aristotle the first statement of two important logical processes—induction, or the collection of particulars from which by critical comparison a generalized result might be drawn, and definition, or the explicit statement of the general elements disclosed by critical comparison of instances.<sup>4</sup> In the Socratic teaching, so far as records go, no explicit reference was made to the problems in connexion with which those processes are of greatest significance, but in the lesser Socratic schools on the one hand, and in Plato on the other, we find the new principle either brought to bear upon the old difficulties, or developed into a comprehensive method.

The Socratic concept contains in itself the union of one and many, but it is in nature subjective; it is a mode of knowledge. If, then, it be regarded as only subjective, the old difficulties reappear. How is it possible to reconcile, even in thought, an opposition so fundamental as that between unity and plurality? Must there not be a like irreconcilable opposition between the subjective counterparts of these objective relations, between the individual notion, the atom of knowledge, and the proposition or definition? How, indeed, can there be a combination in thought of that which is in essence uncombinable? Whether we take Aristippus, who draws mainly for theory of knowledge on the Heraclitic-Protagorean sources, or Antisthenes, who leans towards the Eleatic, or the Megarics, who also, in accordance with the Eleatic thoughts devoted chief attention to the polemical aspect of the theory, we find a set of problems appearing, the solution of which imperatively called for a theory of knowledge as the combination of one and many. Perhaps the most interesting of these early thinkers, as far as the history of logic is concerned, is Antisthenes, whose extreme nominalism presents the most curious analogies to some recent logical work.<sup>5</sup> According to Antisthenes, "the world of sog

<sup>1</sup> For a notice of works on the history of logic, see note A p. 802.

<sup>2</sup> For a notice of some of the more developed systems of Oriental logic, see note B p. 802.

<sup>3</sup> The above translation, which is somewhat free, is taken from Mr Post's edition of the *Sophistici Elenchi*, p. 95.

<sup>4</sup> *Metaph.*, 1078b, 27-29.

<sup>5</sup> On Antisthenes, see the third part of the *Theaetetus*, which appears, beyond doubt, to refer to him (comp. Peipers, *Untersuchungen über das System Plato's*, 1874, pp. 124-48), and Aristotle, *Metaphysics*, 1024b, 32; 1043b, 24; *Topica*, 104b, 21.

namable fact consists of combinations of elementary parts (*πρῶτα*). These *πρῶτα* appear in cognition as irreducible elements denoted by the simplest elements of speech, names. The name is the mark for the sense-impression by which each *πρῶτον* is communicated to us, for they are only known by sense, and are strictly individual. A composite thing is known through the combination of names of its parts, and such a combination (*συνπλοκή*) is a proposition or definition (*λόγος*). Each thing has its specific *λόγος* (*οὐκείος λόγος*), and a judgment is merely the expression of this. There is therefore no distinction of subject and predicate possible; even identical propositions, the only possible forms under this theory, are mere repetitions of the complex name. Predication is either impossible or reduces itself to naming in the predicate what is named in the subject. It is the simple result of so consistent a nominalism that all truth is arbitrary or relative; there is no possibility of contradiction, not even of one's self.

The theory of Antisthenes, strange as it may at first sight appear, rested on certain metaphysical difficulties, which lie at the root of all the perplexity regarding the import of propositions, and it is not too much to say that these difficulties were kept continually in mind by Plato and Aristotle in their several attempts to explain the nature of knowledge. Both thinkers find themselves confronted with the ultimate question, What is the ground of unity in things known, and in what way does thought unite the detached attributes of things into a subjective whole? What is the nature of the unity which binds things, themselves in a sense units, into classes or wholes, and how comes it that in the judgment subject and predicate are, in a sense, set at one?

In Plato, for whom the solution was found in the participation in or imitation of ideas by things, we find more distinctly conceived the series of logical processes involved obscurely in the Socratic method. So far as positive statements regarding the ideas can carry one, it may be said that in essence these processes concern only the formation of or deduction from the concrete universal concept or general notion. The ideas, in the Platonic system, at least in reference to the thought which apprehends them, resemble most closely class notions. A deeper significance often appears to attach to the relative processes of *induction*, whereby the resemblances of things, the idea in them, is disclosed, *definition*, whereby the content of the idea is made explicit, and *division*, whereby the external connexion of ideas with one another, their system, is deduced, but such significance attaches to the more purely metaphysical aspects of the theory, and had no particular bearing on the Aristotelian treatment of the same problems. Not much is given in Plato towards a theory of the proposition, though sometimes an analysis of its elements is sketched; and the method of division could yield only a few of the types of deductive reasoning. But, over and above these more definite contributions towards the construction of a theory of knowledge, there are general aspects of the Platonic work of not secondary importance for the Aristotelian logic. In Plato the fundamental differences of earlier philosophic views appear in a new phase, and are elevated to a higher stage. Sophistic method is analysed, not as in forms actually existing, but in its essential features, and the opposition between sophist and philosopher is viewed as the opposition between opinion and knowledge. Heraclitic principle of change and Eleatic doctrine of unity are resolved into the more comprehensive opposition of the universal and the particular, while hints of an ultimate solution, of a universal which is at once and *per se* particular, are not wanting. The Socratic method of thought appears as that by which alone a solution of philosophic difficulties is to be obtained, and the consideration of thought in its relation to facts is marked out for special investigation. A deeper view of thought was thus made at once possible and necessary.

8. (b) Much, then, had been effected by Aristotle's predecessors in the way of preparing a definite body of problems and a method of dealing with them, problems and method which might fairly be said to belong to a theory of knowledge as such, and from the occasional references in the *Organon* to opinions of contemporaries it is evident that many isolated attempts at solution of such questions were being carried on. In Aristotle we find a systematic examination of many of these problems, but it is left by him doubtful what place in the general scheme of philosophic sciences should be assigned to it. The distribution into physics, mathematics, and first philosophy, or the wider classification of doctrines as poetic, practical, or theoretical, in no way enables us to class logic or the body of speculations making up the *Organon*. That the forms of proof analysed in these writings are of universal scope is unambiguously declared; that the first principles assumed in all proof are dealt with in first philosophy is also made clear; but the relations between the two doctrines so reciprocally related cannot be determined from any statement made by Aristotle himself. That he should have regarded the inquiries of the analytics as propædæutic in character, and should have held that those who came to discuss problems of first philosophy ought to have made themselves acquainted with the general theory of proof, is intelligible, and more than this significance cannot, we think, be assigned to the passage in the *Metaphysics*, on the ground of which the logical

inquiries have been classed as the general, common introduction to the whole system.<sup>1</sup> For the close connexion between the analytical researches of the *Organon* and the inquiry into essence or being as such forbids us to accept, in any strict sense, a separation of these as forming distinct and independent sciences. To metaphysics is assigned the consideration of the principles of proof, and the kind of inquiry making up first philosophy is described by Aristotle in a fashion which assimilates it most closely to the researches of the analytics. That which is left undecided by the Aristotelian classification is the relation of the logical inquiries to the organic whole of which first philosophy is the main or sole part.<sup>2</sup> To obtain any fresh light we must turn to the consideration of indications supplied by Aristotle as to the nature of the inquiries grouped under the head *Analytics*.

9. (c) Such indications are unfortunately most scanty. As we probably have not the *Metaphysics* in its full extent, actual or contemplated, the want of a clear separation between the inquiries belonging specially to first philosophy and those appropriate to the analytical researches may be due in part to the deficiency of our materials. There are, however, two lines of separation discernible, from which some useful inferences may be drawn. What we call the logic of Aristotle, *i.e.*, the treatises making up the *Organon*, is roughly divisible into three parts:—(1) the formal analysis of syllogism and its allied types of reasoning, with the more particular discussion of the elementary parts of reasoning—the proposition; (2) the theory of scientific proof and definition (*apodictic*); (3) the theory of probable arguments, or of reasoning based on currently received opinions and leading to conclusions more or less probable (*dialectic*). Certainly for Aristotle there was no such distinction between the first and the remaining two parts as would in any way correspond to the modern separation of general or formal logic from the theory of knowledge, or material logic; the three parts in conjunction make up one body of doctrine. Now *dialectic* is very specially indicated as being of a formal character, *i.e.*, as dealing with no special matter, but with *κοινὰ*, opinions, or types of opinions common to all sciences.<sup>3</sup> *Apodictic*, we may assume, is in like manner the formal study of what constitutes knowledge strictly so-called, the nature of the principles on which knowledge rests, the special marks distinguishing it, and the method by which knowledge is framed. But in every body of doctrine we may distinguish, according to Aristotle, three things,—the genus or class of objects with which the demonstration is concerned, the essential or fundamental attributes, qualities of these objects, which are to be demonstrated of them, and, thirdly, certain common axioms or principles of demonstration, not themselves demonstrable, and not entering as integral parts into the demonstration, but lying in the background as security for the reasoning carried out by thought employing them. Can anything corresponding to these three facts be discovered, if we assume for the moment, what certainly is not explicitly stated by Aristotle, that analytic constitutes a special body of doctrine? The genus or class about which the doctrine is concerned can only be reasoning itself, either as *apodictic* or *dialectic*, and the latter for a special reason may be left out of account; *ἀποδεικτικὴ*, then, is the matter concerning which the doctrine is put forward. But *ἀποδεικτικὴ* is a form of knowledge, that is to say, is subjective. The properties, therefore, of apodictic science can only be made clear if we consider on the one hand the objective counterparts of necessity and universality in thought, and on the other hand the nature of universality and necessity of thought itself. The common principles or axioms, finally, can only be such presuppositions as are made in apodictic or reasoning generally respecting thought in its relation to fact, as grasping or apprehending reality. The consideration of such axioms, it has been already seen, pertains to first philosophy. Analytics then would appear as an independent doctrine, holding of first philosophy on the one hand, both in regard of the common axioms and in regard of the attributes of being, by which it is a possible object of science, and on the other hand referring to the subjective treatment of thought, whether in relation to principles or to fact generally.

A very similar result may be attained if we follow out a line of distinction indicated in more than one portion of the *Metaphysics*.<sup>4</sup> Separating the modes in which being is spoken of into four—(1) *τὸ ὂν κατὰ συμβεβηκός*; (2) *τὸ ὂν ὡς ἀληθές καὶ τὸ μὴ ὂν ὡς τὸ ψεῦδος*; (3) *τὸ ὂν κατὰ τὰ σχήματα τῆς κατηγορίας*; (4) *τὸ ὂν δύναμει καὶ ἐνεργείᾳ*—Aristotle excludes the second from the special researches peculiar to first philosophy, the study of being as being, but neither excludes it from general consideration in metaphysics as a whole,

<sup>1</sup> *Metaph.* iv. 1005b, 2. See Zeller, *Ph. d. Gr.*, II. 2 (3d ed.), p. 184, n.; Ransow, *De Definit. Not.* 46, 47; Schwegler, *Comment. zur Metaph.*, III. 161; and, e. Prantl, *Gesch. der Logik*, I. 137. Zeller maintains the view that Aristotle intends to indicate the place occupied by the analytics in his general scheme of philosophy.

<sup>2</sup> On Aristotle's use of the term *λογικός* and its allies, see (in addition to Waltz, *Com. in Organ.*, II. p. 353-55) Schwegler, *Commentar zu Ar. Aristotel.*, vol. IV. p. 48-51.

<sup>3</sup> See *Anal. Post.*, I. 11; *Rhet.*, I. 1, and in many passages. Cf. Heyder, *Method. d. Arist.*, p. 348.

<sup>4</sup> *Metaph.* vi. 1, v. 29, ix. 10. Cf. Schwegler, *Com.*, III. 241, iv. 29 sq., 125; and Bruntano, *Bedeutung des Seienden nach Arist.*, 91 sq.

nor handles it at length, deferring it rather for more detailed treatment. A comparatively clear account, however, of what is understood by him under the head of being as truth and non-being as falsity may be extracted from the various passages referred to, and little doubt can remain that being so regarded is in a peculiar sense the matter of analytical (*i.e.*, logical) researches.

Being as truth and non-being as falsity refer to and rest upon combination and division of the elementary parts of thought. For truth and falsity have no significance when applied to things, but only to the connexion of thought which is dominated by the one principle of non-contradiction. Nay, thinking has not even immediate and direct reference to being as such, but only to being as the existent, as qualified, or quantified, or modified in some other way (*i.e.*, according to the categories), and it is in its very essence the conjunction or unifying of elements. What cannot be conjoined, as, *e.g.*, the notions of elementary facts themselves, are not either true or false, and are not matters of thought. Thought thus moves in a definite sphere, that of the combinable or separable, the correspondence of conceptions with real relations, and has its limits on the one hand in the elementary data apprehended by intellect (*νοῦς* = reason), and on the other hand in the infinite sea of particular, accidental qualifications of things (*συμβεβηκότα*). The possibility of contradictory assertions (for true and false judgments together make up the contradiction, *τὸ δὲ σίναλον περὶ μερισμῶν ἀντιπαράσας*) is the distinguishing mark of thought. Now it is this very possibility that lies at the root of all the analytical researches. Not, indeed, that one can assume for Aristotle a view which has appeared in later logical works, that all forms of logical reasoning are to be deduced from the principle of contradiction. Quite the reverse. The common axioms underlie all processes of proof, direct or indirect, but they do not enter into or form part of proof. Nothing can be deduced from them; but their authority can be appealed to against any one who refuses to allow a conclusion reached by a correct syllogism from true premisses.<sup>1</sup> (The nerve of logical proof would thus lie in the disjunctive proposition; either this conclusion is to be granted or the principle of contradiction is denied.) Now the analytical researches are in especial the treatment of combination and separation in thought. For even the syllogism may be regarded as only a complex judgment or synthesis, and in the exposition of the forms of combination and separation we shall find a complete system extending from the unproved principles and exhibiting the methods according to which thought proceeds towards the determination of the essential properties of things or the discrimination of various kinds under which the transitory and accidental attributes may be advantageously classed.

So far then as one may judge, the matter of Aristotle's analytical researches may be expressed as the concrete nature of thought, characterized by its fundamental attribute, the possibility of contradiction, correlated with the real system of things, and having as its end the realization of systematic knowledge, *i.e.*, the adequate subjective interpretation of being.

10. The indication that the analytics have to do with being as conceived by thought, conducted under the general axiom of non-contradiction and expressed in language, requires to be filled up by a more detailed treatment of the Aristotelian theory of thought in relation to being. Upon the characteristics assigned to thought or knowledge in this special relation, must depend the general nature of the Aristotelian logic, the determination of the scope of logical treatment, and the essence of logical method. For from a quite similar statement regarding the province within which logic moves, totally diverse conclusions might be drawn respecting the precise function of logical method. One might have either a formal doctrine or *technic*, or a real methodology, either an attempt to evolve logical principles from the axiom of contradiction, or a development of the laws according to which thought, necessarily acting under the said axiom, proceeds towards the construction of knowledge. The history of logic clearly shows how differently the matter of the analytics may be viewed. For one of the possible conclusions, that logic is a technic or quasi-mathematical exposition of formal relations, has been accepted as the undoubted result of Aristotle's teaching, and has so prevailed as to make itself the cult of convention.<sup>2</sup> The other, the view of logic as theory of the method of scientific thought, has been cast entirely into the background, so far as logical doctrines are concerned, and, if allowed at all, has been regarded as foundation for a species of applied logic, an appendix to the other.

11. Not much aid is afforded directly by any classification or division of the books now collected together as the *Organon*. As above noted, the *Logic* and *Posterior Analytics* with the *Topics* form one connected whole, while the *Categories* and the *De Elenchi* stand apart as isolated treatments of special problems, not organically or necessarily part of the research. The genuineness of both these treatises has been doubted (see ARISTOTLE, vol. ii. p. 514), and it is not improbable that both are redactions of Aristotelian

material, perhaps drawing from other lost writings of Aristotle, perhaps based on oral teaching, by some Aristotelian scholar. A summary view of the contents of the other books will be found at vol. ii. p. 516.

12. The logical researches as a whole manifest a strong unity, and at the same time refer to one fundamental opposition, that between *apodictic* and *dialectic* reasoning.<sup>3</sup>

The opposition between apodictic and dialectic is in the Aristotelian system the development of that which had already played so important a part in Plato and Socrates, the distinction between science and opinion. Knowledge in the strict sense had there presented itself as the generalized notion referring to being in its very essence, and resting on thought or reason. Opinion is the quasi-knowledge of the particular, referring to that which is not being but only accident, and resting on sense or imagination. In the Platonic method this distinction had come forward as the underlying basis for the opposition of philosophy and sophistical rhetoric; in Aristotle a much more precise formulation is given of the characteristics of the two opposed forms of thought, and the connexion between opinion or dialectic and rhetorico-sophistical discussion is made more concrete and profound. Dialectic, with Aristotle, is the system resulting from the attempt to reduce to rule or generalize modes of argument which rest upon current received doctrines as principles, which move within the region of interests about which current opinions *pro* and *con* are to be found, and which terminate not in the decisive solution of a problem but in clearing the way for a more profound research or at least in the establishment of the thesis as against an opponent. Dialectic, then, has no special province; it deals with *κοινὰ* or *ἐνδοξα*, and its methods are perfectly general. On the one hand, as being the application of reasoning, it refers to and employs the specific types of reasoning, syllogism and induction; on the other hand, as being applied to matters of opinion, and borrowing its principles from current floating dicta about matters of common interest, the types of reasoning tend in it to assume special forms resembling those employed in rhetoric (which is a kind of offshoot from dialectic—the application of dialectic to political principles). The province of dialectic being thus essentially vague, the matters about which dialectic reasoning is concerned being of the most fluctuating character, there must be, for Aristotle, the greatest difficulty in determining, *per se* and apart from the opposition to apodictic, what is the character of dialectic syllogism and induction. Nor can it be said that the interpreter of Aristotle has an easy task in the endeavour to discover what precisely is dialectical reasoning and in what way the forms which are assumed to be common both to apodictic and dialectic come to have any application to the fluctuating mass of current opinions. It is comparatively simple to say apodictic and dialectic differ in this, that the one rests on principles essential, necessary, seen to be true, while the other proceeds from data which are merely received as credible and as containing probable, received opinions on a subject about which there may be difference of view; and it may be added that in the one we reach conclusions which are essential, in which the predicate is necessarily and universally true of the subject, while in the other the conclusion remains, like the data, credible merely, and is, at best, only one of the probable answers to a question. But there remains the difficulty, which is certainly not cleared up by any direct statement from Aristotle—of what nature is the syllogistic inference that applies to material of this kind? what is the *veritas probabilis* in a dialectic syllogism? There are two possible views—either that the principle of syllogistic inference is purely formal, deducible from the characteristic of thought as either affirming or denying in reference to a particular subject, and therefore capable of application either to probable or to necessary matter, or that the syllogism is explicable only as a form in which knowledge is established and is applicable but *per accidens*, as one may express it, to probable matters. Under this second view, the possibility and reality of syllogistic inference would be traced to the correlative peculiarities of human thought and of the nature of the objects of thought, and it would follow that in strictness there is no dialectic syllogism. Such a conclusion at first sight appears to stand in sharp opposition to quite emphatic utterances of Aristotle, but if we suppose, for the sake of example, that a dialectic syllogism were framed, we should readily discern that the link of connexion between data and conclusion, the *veritas probabilis*, as it may be called, does not in fact differ from that involved in the apodictic syllogism. The merely probable character of the data prevents the conclusion

<sup>1</sup> The most important treatments of the principles and details of the Aristotelian logic, which are here drawn upon freely, are (1), *instaur omnium*, that of Prantl (*Gesch. d. Logik*, I. pp. 87-346); (2) that of Brandis, *Aristoteles*, pp. 118-431, and *Aristotelisches Lehrgebäude*, pp. 12-82 (in which there is sharp criticism of Prantl's view); (3) that of Gericke, *Aristoteles*, vols. I. and II. pp. 1-134 (most patient and accurate, but tending continually to minimize the speculative element); (4) that of St. Maurel, in his essay *De la Logique d'Aristote*, 2 vols., 1898, and in his translation of the *Organon*; (5) that of Meiss, *Phil. d. Arist.*, I. 44-319. Treubner's *System der Logik Aristoteles*, Walz's edition of the *Organon*, and Ueberweg's *System der Logik* contain much of value. Mr. Poste's translation of the *Post. Anal.* and *Sophis. Elenchi*, Mr. E. Wallace's *Outlines of the Phil. of Aristotle*, and Mr. Magrath's *Selections from the Organon* will also be found of service.

<sup>3</sup> Cf. Brandis, *Gr.-rom. Phil.*, II. 378-75.

from having a higher value than mere likelihood, but does not affect the chain of inference, which proceeds on assumptions identical with these involved in apodictic. Aristotle is chary of any examples of dialectic syllogism, and indeed, if one considers that all forms of modality are investigated in the general analysis of syllogism, it becomes difficult to see what specially distinguishes dialectic inference. It is not to be denied, however, that the investigation of the grounds for the coexistence of dialectic and apodictic is incomplete in Aristotle, as it confessedly is in Plato.

Unless, then, it can be shown beyond possibility of question that Aristotle does lay down purely formal rules for syllogism, rules deducible simply from the fundamental axiom of thought—and the evidence on which such a view is based will be examined later—we do not obtain much light from the opposition between dialectic and apodictic. More important results, however, are gained when we consider the Aristotelian doctrine of genuine knowledge, of *ἀποδείξεις*, for, among the numerous elements that here fall to be noted, some are of quite general import, and apply to the whole process of the formation of knowledge.

13. Apodictic knowledge generally is definable through the special marks of its content. It deals with the universal and necessary, that which is now and always, that which cannot be other than it is, that which is what it is simply through its own nature. It is the expression of the true universal in thought and things, *τὸ καθόλου*. Further, as a method, *ἀποδείξεις* is characterized by the nature of its starting point, and of the connecting link involved, as well as by the peculiarity of its result. It rests upon the first, simplest, best known, unprovable elements of thought; the *πρώτα καὶ ἁμέσα*, which are not themselves in the strict sense matters of apodictic science, which are *ἀναπόδεικτα*. In all the intermediate processes of scientific proof there is involved generally this dependence upon previously established principles, and, when apodictic is taken in its ultimate abstraction, these previously established principles are seen to be the prior, ultimate elements, assumptions in thought about things, as one may provisionally describe them. The peculiar connexion involved is simply what we understand by the principle of syllogism. No syllogism is possible without the universalizing element, the *καθόλου*, and knowledge in its essence is syllogistic.<sup>1</sup> The conclusion of the syllogism in which essential attributes are attached to a subject is the conversion or closing together of the two aspects of all thought and being, the universal and particular.<sup>2</sup>

The fuller explanation of apodictic thus refers us to three points of extreme importance in the Aristotelian theory of knowledge, the precise nature of the *καθόλου*, which presents itself as the characteristic feature of *ἀποδείξεις*, the relation of fundamental and universal in things on which the possibility of *ἀποδείξεις* is founded, and the forms of thought through which the universal and particular factors are subjectively realized. The three are most closely connected, and as they involve the main difficulties of the Aristotelian philosophy as a whole, a general treatment of them is indispensable. First then of *τὸ καθόλου*, the characteristic term in the explanation of knowledge. This notion is essentially double-sided. On the one side it is the universal of empirical knowledge, the generic or class universal—it is *τὸ κατὰ παντός*; on the other hand, it is the root or ground of the empirical universal—it is *τὸ καθ' αὐτὸ καὶ ἡ αἰτία*,<sup>3</sup> that which is in, for, and through itself, the essential. Now the essential, *καθ' αὐτό*, is, in the first place, either that which enters into the being and notion of a thing as a necessary prerequisite (for example, *line* is a necessary element in the being and notion of triangle), or that which is the necessary basis of an attribute (e.g., *line* in reference to *straight* and *curved*), or in the second place that which is as subject only and not as predicate, or finally that which is *per se* the cause or ground of a fact or event.<sup>4</sup> Thus the function of thought (of apodictic) is the exposition with reference to a determined class of objects of all that necessarily inheres in them, on account of the elementary factors which determine their existence and nature. Real things, individual objects, are the basis of all knowledge, but in these individuals the elementary parts, causally connected, and leading to ulterior consequences, form the general element about which there may be demonstrative science. Thought which operates upon them does so, as we have already seen, under the peculiar restriction of its very nature, as the subjective reali-

zation of the notion of things, and the principles expressing this restriction, the logical axioms, may be appealed to if demonstration be opposed groundlessly, but these axioms do not enter into the process of demonstration. "When the apodictic process has attained its end, that is, when all the universal propositions relating to a given class, with insight into the necessary character of the predication in each case, have been gathered up, then the *καθόλου* of knowledge in respect to that class has been realized."<sup>5</sup>

14. Probably the example of apodictic which Aristotle bears chiefly in mind is mathematical science, and in his treatment of the characteristic marks of this doctrine most of the peculiarities of apodictic occur. In mathematical science abstraction is made of the material qualities of the things considered, of those qualities which give to them a place as physical facts, but the abstracts are not to be conceived as entities, self-existing. They are not even to be conceived as existing only in mind, as ideal types; they truly exist in things, but are considered separately (*τῶν σφαιρισμάτων*). The first principles of mathematical science are few and definite, and the procedure is continuously from the simple and absolutely more known to the concrete and relatively more known. As in proof generally, so in mathematical demonstration, an essential quality (*συμβεβηκός καθ' αὐτό*) may be proved of a subject, and yet such quality may be still accidental, *i.e.*, not predicated of the subject on account of its generic constituent marks, but capable of being deduced from the constituent mark of that which enters into the subject, as, e.g., a given figure's exterior angles are equal to four right angles. Why? Because it is an isosceles triangle. Why has an isosceles this property? Because it is a triangle. Why has a triangle? Because it is a rectilinear figure. If this reason is ultimate, it completes our knowledge, *καὶ καθόλου δὲ τότε*.<sup>6</sup> Thus the range of mathematical proof extends from the *πρώτα*, the original definitions, which at the same time assume the existence of the things defined, through the determinations *καθ' αὐτά* to the qualities (*συμβεβηκός*), which can be shown to attach to their subjects, to be in a sense *καθ' αὐτά*, while a continuous series of middle notions, concerning which there cannot be much ambiguity, effects the transition. Moreover, in mathematical science, one can see with the utmost evidence the correlation of reason and sense, which will presently appear as a fundamental factor in Aristotle's general theory of knowledge. The *πρώτα* are not to be conceived as innate or as possessed before experience. They are seen or envisaged, intuited in perception by *νοῦς*, and induction here as elsewhere is the process by which perceptions are gathered together for the reflective and intuiting action of *νοῦς*. In the mathematical individual, more evidently than in any other case, is visible the union of thought and sense. The demonstration which employs a diagram does not turn upon any properties of the diagram which are there for sense only, not for reason, but upon the general elementary relations contemplated in thought.<sup>7</sup> In mathematical development, that which is potentially contained in the *ἐκτενερῆ* on which mathematical thinking operates is brought forward into actuality by the constructive processes through which the proof is mediated, and the potential knowledge contained in the intuition of mathematical elements becomes actual through the process of constructive thought.<sup>8</sup>

Finally, the relation of pure mathematical reasoning to that found in sciences generically one with mathematics, *e.g.*, optics, astronomy, harmonics, &c., furnishes an interesting example of the relation between reasoning based on fact and on causal ground.<sup>9</sup>

15. The process of *ἀποδείξεις* generally and of mathematical demonstration in particular has brought into clear light the prominent characteristic of knowledge according to the Aristotelian view. Knowledge must always be regarded from two sides, as having relation to the universal, and as bearing upon the particular.<sup>10</sup> It is in itself the union of the general and the particular, of the universal and the individual. This fundamental notion of knowledge is not only the integral element in the Aristotelian theory of science, but also the guiding principle in his scientific method.<sup>11</sup> In all cases we require to keep in mind the necessary correlation of the particular facts and the general grounds, the multiplicity of effects and the unity of cause. The one element is not apart from the other. Universals as such are of no avail either as explanations of knowledge or as grounds of existence. Particulars as such are infinite, indefinite,

<sup>1</sup> Cf. *Topica*, pp. 164a, 10.

<sup>2</sup> See specially *Anal. Pr.*, 67a, 39 sq., and compare the elaborate note of Kampe, *Erkenntnistheorie des Arist.*, p. 220 (also p. 84). Grote (*Aristotle*, I, p. 263a) remarks: "Complete cognition (*τὸ ἐννοεῖν*, according to the view here set forth) consists of one mental act corresponding to the major premiss, another corresponding to the minor, and a third including both the two in conscious juxtaposition. The third implies both the first and the second." The connexion between this and the Aristotelian doctrine of *νοῦς* in its relation to *αἰσθησις* will not escape attention.

<sup>11</sup> This is excellently put by Lucken, *op. cit.*, pp. 44-55.

and incognizable. Only in the union of these, a union which objectively regarded is the combination of form and matter, of potentiality and actuality, of genus and ultimate difference, subjectively is the combination of the data of sense, imagination, and intuitive faculty of reason, is knowledge possible. And the methods by which knowledge is formed in us regarding things exhibit the same twofold aspect. Syllogism as the form of the process from generalia to the determination of attributes of the individual subject, induction as the method of procedure from the vaguely apprehended individuals to the generalia or principles, alike, when analysed, exhibit the conjunction of the universal and particular.

16. In each branch of knowledge there are involved the specific genus or class, the attributes concerning which there is to be demonstration, and the common axioms or principles. Each branch, moreover, implies special principles, *ἵδια ἀρχαί*; there is no all-comprehensive science from which truths are to be deduced, and from the common maxims alone nothing can be inferred. *Ἀποδείξεις* involves principles, and starts therefore of necessity with what may be called definitions. Yet definitions are at the same time the final result of apodictic demonstration, and the original assumptions may be pushed farther and farther back till they appear as the *πρώται καὶ ἁμίστοι προτάσεις* which are only apprehended by *νοῦς*. From this distinction between knowledge as completed and knowledge as in process of formation, as from the distinction between sciences of the same genus as more or less general (e.g., geometry and optics), there follow the distinctions between propositions necessary and propositions true *ἐπὶ τὸ πᾶν*, between proof of fact and proof of essence, between deduction and induction, between syllogism as generic form of all proof, and the special type of syllogism in which completed knowledge is expressed. We are thus enabled to reconcile what seem at first sight discrepancies in the Aristotelian doctrine,—as, e.g., the insistence upon induction as furnishing the principles of reasoning (*τὰ καθόλου*) coupled with the attempt to show that induction too is a kind of syllogism; the explanation of proof as involving essence, coupled with the admission of syllogisms of fact; the treatment of propositions as necessary and contingent in themselves, coupled with the distinction between *ἐπιστήμη* and *δόξα*. In all forms of knowledge there is the twofold aspect, that which turns upon the essential connexions, and that which refers to the isolated facts wherein such connexions make their appearance. Syllogistic as formal analysis of what is common in all knowledge is one part of the all-comprehensive theory of knowledge, an integral but not a self-existing part.<sup>1</sup>

17. The general idea of the Aristotelian analytic thus obtained does not require to be supplemented by any detailed survey of the logical system into which it is evolved, but a brief summary of the most important points and indication of the relation in which the parts stand to the whole may be of advantage.

The simplest form of knowledge, that in which being as true or false is apprehended, is the judgment. The consideration of the judgment is therefore the first part of the analytical researches. Here Aristotle distinguishes more accurately than any of his predecessors (indeed for the first time with accuracy) between subject and predicate as integral parts, symbolized by the noun and verb, and signifying the relations for us of things as appearing under the schemata of the categories. The material basis of the judgment, as one may call it, is the thing as an object of possible knowledge, i.e., the thing as individual (and therefore as involving matter and form, the particular and the general), as qualified, specifically, in time, space, quantity, and relation, and existing as one mode in the universal nexus of potentiality and actuality. These metaphysical forms, and, specially, the deep-lying modes of potentiality and actuality, reflect themselves in the forms whereby subjectively knowledge is realized in us, and the resulting knowledge is conditioned partly by them, partly by the modes in which intellect as a reality is developed in us. The proposition has necessarily a reference to them, and thus alongside of formal distinctions between universal, particular, singular, and indefinite judgments we have

the distinctions between necessary, contingent, and possible, which appear partly as given qualities of the judgment, partly as representing differences in the conditions of knowledge, partly as referring to differences of subjective apprehension.

The essence of the judgment as the apprehension of truth or falsehood consists in its twofold aspect as affirmative and negative, the former of these in a sense prior and better known, but the latter no less necessary, and both referring to objective relations of things. The affirmative and negative character of judgments, the essential *ἀντίφασις* of human thought, is further defined in reference to (a) the quantitative distinctions already recognized (the doctrine of logical opposition), (b) the distinctions of necessary, contingent, and possible, which are rightly regarded as real matters about which the assertion is,<sup>2</sup> and (c), consequent on this, the opposition of modal judgments.<sup>3</sup>

Propositions as integral parts of knowledge turn upon the ultimate relations of things known. The distinctions between first principles and deduced truths, out of which the theory of proof is developed, themselves rest upon those distinctions which have been already noted in treating of apodictic. Syllogism as the form by which the general and particular elements are mediated and conjoined is therefore of universal application, and may be analysed formally.<sup>4</sup> The various modes in which syllogistic inference, pure or modal, the main types to which these modes may be reduced, their relations to one another, and the general laws implied in them are worked out in a fashion which does not admit of any brief statement. The conclusion unites the elements which in isolation appear in the premisses, and is, in a sense, the complex or organic whole unfolded in the syllogistic form. To every syllogism three things are necessary, the presence of a positive element, universality in one of the premisses (resting, as above shown, on the recognized property of all proof as involving a general fact), and consequence, or necessary connexion between conclusion and premisses. Now from this third element there follow certain interesting deductions. The necessity of consequence rests on the very nature of syllogistic thought, and if each syllogism be taken as it stands, as a simple unit, no further inquiry is needful. But the character of the premisses in themselves may be taken into account, and we then discover that syllogism proceeds continuously on the assumption that the general law of syllogistic proof is in the special case realized. It need not be in fact realized. We may have premisses in themselves false, from which a true conclusion is reached, and the falsity of the premisses only becomes apparent when they are themselves treated as conclusions of a possible syllogism, and so the regress made towards ultimate principles. Syllogistic form, in short, is the hypothetical application of the general rule of necessary connexion between ground and consequent. If A (the premisses), then B (the conclusion). Quite possibly, then, we may have, in syllogistic form, conclusions drawn from premisses not *ἀναγκαῖα* but only *ὡς ἐπὶ τὸ πᾶν*. Science and opinion (*δόξα*) are equally sources of propositions or premisses. If formal consequences be united with real uncertainty of matter, there arises a syllogism in character dialectical. Were the real uncertainty overlooked, the syllogism would be sophistic in character. Dialectical reasoning, then, dealing with the stage beneath science, may be of service, not only for practice in distinguishing true and false, but as bringing the particulars of each branch of knowledge into closer relation with the first principles special to that branch.<sup>5</sup> For wherever the particular element as such, the transitory and material, is present, there room is left for opinion, and reasoning is possible, not of the particular as such, but in so far as the particular manifests an underlying universal.<sup>6</sup> The processes of dialectic reasoning thus resemble very closely those modes by which the empirical detail, the region of given fact, is treated, viz., induction, example, use of signs and probable indications. For the universal has always its empirical side, and the complete process of scientific proof is a final result for which the way may be prepared by treatment, according to scientific form, of the empirical fact. There are syllogisms of fact as well as syllogisms of reason or ground, and the reason or ground becomes apparent through knowledge of the fact. Occasionally indeed the fact and ground are so immediately connected that transition from one to the other may be at once effected, but generally this is not the case.

Of these intermediate forms of reasoning, the only one calling for

<sup>1</sup> The passages in which an apparently formal view of logical relations is expressed are mainly the following.—*Topics*, I, chap. vi. (in which the fundamental logical forms of definition, genus, property, and accident are explained by reference to the coincidence of the spheres of subject and predicate in a proposition); *Anal. Post.*, I, chap. 26 (*συλλογισμὸς ἔστιν, ὅς ἐστιν οὕτως ἔχων, ὥστε ἡ δόξα πρὸς μέρος ἢ μέρος πρὸς ὅλον ἔχειν*); *Anal. Post.*, II, 3 (*ἐν ᾧ οὐδὲν ἄποδεδίκεται, εἰ μὴ ὡς μέρος ἢ τῆς ὅλης, τοῦτο δὲ λέγω, ὅτι δεῖται τοῦ ἰσοσκελεῖν δύο ὁρθὰς, εἰ πᾶν ἐργάσανον ὀδύκεται, μέρος γὰρ τὸ δόλον*); *Rhetoric*, I, 2, § 19. The general treatment of syllogism in *Anal. Pr.*, I, 4, as apparently resting on the principle of subsumption or logical substitution, has no precise bearing. But the use of the term *δῶν* by Aristotle is not to be regarded as identical with its use by later logicians, and it is not rashly to be assumed that in Aristotle's view the only logical relation is that between genus and species. The distinction between extent and intent, on which later writers have laid stress, is never suffered in Aristotle to become a distinction in kind; the two elements, extent and content (*κατὰ πᾶν* and *κατ' αὐτό*), are always involved, and the difference is only in the process by which our knowledge is formed. Probably the relations of extent and content would never have been severed from one another had it not been for the error, almost a necessary falling in the attempt to treat formal logic systematically, of regarding notions and judgments as completely formed and defined products apart from the reasoning in which they appear (see, for a diametrically opposed view, Hamilton, *Lectures on Logic*, II, p. 386).

<sup>2</sup> On this account the modality is affirmed not to attach to the copula; thus the opposite of "it is necessary-to-be" is "it is not necessary-to-be," and not either "it is necessary-not-to-be," or "it is not-necessary-to-be."

<sup>3</sup> There are obscurities in Aristotle's doctrine of modals, which remain even after Prantl's laborious treatment (*Ges. d. Logik*, I, 104-82). A careful survey is given in Bondelet, *Théorie logique des propositions modales*, 1861. The definitions of *ἐνδεχόμενον* and *ἐμφαντικόν*, which have given rise to much diversity of opinion (cf. Prantl, I, 167 sq., as against Watts, I, 376, and Bonitz, p. 387), are excellently dealt with by Ueberweg, *Logik*, § 69.

<sup>4</sup> In this sense only can we recognize the distinction between Aristotle's *Technik* and his idea of *Apodiktiké* (in which Lange (*Logische Studien*, 1890) has laid so much stress. What underlies Aristotle's treatment must never be brought out of account.

<sup>5</sup> *Topics*, I, 2, §§ 3-6.

<sup>6</sup> On this distinction cf. Kamppe, *Erkenntnistheorie d. A.*, pp. 252, 253; Hayden, *Method d. A.*, p. 252.

It is induction, of the nature of which something has already said. The obscure chapter in which the formal analysis of induction is undertaken, a chapter which has much exercised the ingenuity of commentators,<sup>1</sup> presents difficulties of varied kinds. An opposition is indicated between syllogism and induction, yet induction is treated as a kind of syllogism; that is, freely interpreted, induction is so analysed as to show that in it, also, there is the union of general assumption and particular detail which is characteristic of syllogistic reasoning. Further, Aristotle seems to waver between induction as a kind of inference, through which we arrive at general principles, and as a species of proof, and his teaching is therefore perplexed by the want of some clear statement regarding a difficulty in the theory of induction, which is still far from perfect solution. For, according to Aristotle, induction as such, starting from the particulars of sense, and proceeding by comparison of similar cases and enumeration of all the similarly constituted members, never, even when the enumeration is complete, attains to probative force.<sup>2</sup> It is still a syllogism of fact, not of ground or reason; there is a distinction of kind between the survey of empirical detail, even when complete, and the assertion of causal connexion between the characteristics of the class and its deduced properties.<sup>3</sup> Thus, perception of the law ( $\tau\delta\ \kappa\alpha\theta\acute{o}\lambda\omicron\upsilon$ ) from induction is a kind of new element in the process; it is recognition by means of the empirico-critical survey which is the essence of induction.<sup>4</sup> Induction makes clear only, and does not prove.<sup>5</sup> If we interpret according to more modern phraseology, this peculiarity may be expressed as the distinctive feature of inductive research based on facts or effects. We do not regard the inquiry as terminating in the establishment of a law until it is possible to reverse the process and show that from the admitted cause the effects do actually follow. Otherwise we have a conclusion of "coexistence" merely—an empirical rule or generalization. It, bearing in mind these sources of difficulty, and also the correlation which for Aristotle always obtains between empirical details and grounds of reason, we consider the example given in the obscure chapter before us, some light may be cast on the exposition there given. The example selected is one touched upon by Aristotle in other two passages, in the treatise *De Partibus Animalium*, and in the *Post. Anal.*, ii. 18.<sup>6</sup> As regards the first of these, reference is desirable only to bring out the fact that causal nexus is the  $\kappa\alpha\theta\acute{o}\lambda\omicron\upsilon$  in question; the second is of the utmost importance as clearing up what has always seemed an obscurity in the account of the inductive syllogism. In the chapters 16-18 of *Anal. Post.*, ii., Aristotle considers the relation of cause and effect as the essential basis of proof, and he points out with much clearness the difference between the fact as cause of knowledge and the cause as ground of existence and proof. In some cases cause and effect are so united, so reciprocate, that we may infer from one to the other. But the doubt arises, may there not be more than one cause for any given attribute, in which case all such inferences from effect must become problematical. Aristotle's solution is remarkable, both in itself and in its bearing on the inductive syllogism. Suppose the attribute  $\beta$  is found in all individuals of a class A, and also in individuals of class B, C, &c. In order to discover the cause, investigations must be carried on until we have a defined number of classes A, B, C, &c., in all of which  $\beta$  is found, and which comprehend all cases of the presence of  $\beta$ . Then that which is also common to A, B, C, &c., may be regarded as the cause of  $\beta$ , say, e.g., an attribute  $\alpha$ . If this attribute  $\alpha$  be really the cause of  $\beta$ , it will enter into its definition; it will be its definition. There might, however, be a connexion of  $\alpha$  and  $\beta$  of this universal and reciprocating kind, and yet  $\alpha$  might not be the cause in question; it might be only a fact from which  $\beta$  could be inferred; the real cause  $\gamma$ , which gives rise to  $\alpha$ , lies in the background. Characteristic of causation, then, is constant reciprocal conjunction of facts. Even if it be admitted, then, that there may be more causes for a phenomenon than one, it will yet be true that each of these causes will be manifested in one class of phenomena where there will be the universal reciprocating coexistence that is characteristic of the relation in question. Thus the attribute longevity observable in quadruped animals and in birds may be due to different causes, e.g., to absence of gall in the one case, to predominance of solid, dry matter in the other. But in each case there will be a definite species characterized by the constant conjunction

of the cause and the causatum; the whole class long-lived animals and the class gall-less animals will coincide.

Turning now to the chapter on inductive syllogism, we find induction defined as inference through the minor that the major belongs to the middle. Here evidently major and middle are regarded not as determined by form only but naturally distinct, and we must assume that by middle term is to be understood the ground or reason of the attribute (major term) characteristic of a defined species or group (the middle term). Were our knowledge complete and scientific, we should be able to express this in apodictic form:—whatever animal has no gall is long-lived; man, horse, mule, &c., are animals having no gall; therefore they are long-lived. The progress of knowledge, however, may be from the empirical details. We may have given to us the fact of the attribute, long-livedness, in the group of animals, man, horse, &c., and discover that these long-lived animals are also wanting in gall. If then, in accordance with the rules above sketched, there can be discovered a reciprocating relation between want of gall in animals and long-livedness, if we can constitute a class distinguished by conjoint presence of gall-lessness and longevity, we have the basis for an inductive proof. We may infer therefrom that gall-lessness is, in this species, the cause of longevity. Such a reasoning is founded on particulars given, and as the coexistence is given, the conclusion seems to be immediately drawn; there does not appear to be mediation or use of a middle term; nevertheless the middle term is implied, not in the supposition that the two classes reciprocate, but in the transference from empirical coexistence to causal nexus.

Aristotle's mode of stating this argument has presented so many difficulties of interpretation that various emendations have been proposed. Grote, e.g., who has not apprehended why the class long-lived animals should be taken universally,—“we are,” he says, “in no way concerned with the totality of long-lived animals,”—suggests an emendation, which makes the essence of the inductive reasoning turn upon the extension of what we know regarding some gall-less animals to all of that class. But this is not the inductive step according to Aristotle. Induction has not to prove or assume that  $\alpha$  and  $\beta$ , found coexisting in some members of a species, coexist in all of them; Aristotle takes this universal coexistence for granted as the basis of the argument. The inductive step is the transference from this universal coexistence to causal nexus. Apodictically, we should say, if  $\alpha$  is the cause of  $\beta$ , then all A which possesses  $\alpha$  possesses  $\beta$ ; thus reasoning from cause to causatum. Inductively we say, all A which possesses  $\alpha$  has  $\beta$ ; therefore  $\alpha$  is the cause of  $\beta$ .

Induction, as dealing with particulars, starting with the sense data, and resting upon the more evident fact in order to point towards the essential ground or reason, is therefore more persuasive, more palpable, more adapted for popular inquiries, and relatively more apparent. Syllogistic proof, on the other hand, is more stringent, and more efficacious in establishing a scientific conclusion or position.

Aristotle's mode of dealing with induction, in so far at least as any specific process is designated by that term, seems on the surface to diverge widely from modern logical theory, and we look in vain in his analytical researches for consideration of the methods of observation and experiment which has come to be recognized as the essential portion of a doctrine of inductive reasoning. Yet it may fairly be argued that in modern theories the term induction is used with great laxity, so as to cover either all processes connected with scientific method or some one special feature of scientific reasoning, and that the difference between the Aristotelian and modern views

<sup>1</sup> The following is the relative portion of chap. 23 of bk. ii. of the *Anal. Pr.*:—“Now induction and syllogism through induction is the process of concluding by means of the minor term that the major term is predicable of the middle” (that is to say, of concluding from given facts that an attribute found in all of them is the effect of some other attribute also found in all of them). “For example, if B be the middle term, A and C the extremes, we show, by means of C, that A is predicable of B; for this is the inductive process. Thus, let A be long-lived; B, those wanting gall; C, individual long-lived, as man, horse, mule. Then A is predicated universally of C” (that is to say, the attribute A is found in all the examples before us), “for also that which wants gall is long-lived” (that is to say, as a given fact, gall-lessness and longevity in the species, group, before us coexist). “B, wanting gall, thus is predicated universally of C. If then B and C be reciprocating, if C do not extend beyond the middle term” (that is, if we do not find other animals than the long-lived animals enumerated which also are devoid of gall), “it is necessary that A should be predicated of B. For it has been shown previously that if two terms are predicable of the same third, and if the extreme reciprocate with one of these, then the other of those predicates will be predicable of that with which the first reciprocated; but it is necessary to know that C is the complex of all the individual cases.” The last sentence is extremely hard to interpret. The expression  $\tau\delta\ \alpha\epsilon\pi\omicron\upsilon$  occurring in it is generally the technical word for major term, but as in the syllogism before us the major term is one of the predicates, this signification would seem to contradict the words  $\kappa\alpha\theta\acute{o}\lambda\omicron\upsilon$   $\alpha\upsilon\tau\omega\upsilon$ . Hamilton reads  $\tau\delta\ \mu\epsilon\sigma\omicron\upsilon$ , which makes the argument intelligible and coherent with the passage apparently referred to in *διδέσκειται*  $\pi\omicron\tau\epsilon\omicron\upsilon\sigma\iota$   $\nu\iota\zeta$ , *Anal. Pr.*, ii. 21, p. 68a, 31-25. Probably Aristotle uses  $\tau\delta\ \alpha\epsilon\pi\omicron\upsilon$  here as equivalent to C, the  $\alpha\epsilon\pi\omicron\upsilon$  through which the induction proceeds. According to the view taken above, the essence of the Aristotelian induction does not at all lie in the universalizing of C, but in connecting in one proposition the attributes B and A found to coexist in the group C. There is thus in one sense no middle, for cause is not reached; in another sense there is, for C is the material link connecting A and B. Aristotle then might naturally use  $\alpha\epsilon\pi\omicron\upsilon$  for C, and assimilate the process of induction to a syllogism in which there was reciprocation of terms. In fact, however, induction regarded after his fashion results merely in the constitution of a group or class characterized as possessing two attributes in common.

<sup>2</sup> *Anal. Pr.*, ii. 23. Cf. Whewell, *Camb. Phil. Soc. Trans.*, vol. ix., 1856; Hamilton, *Lectures*, ii. 388-82; Grote, i. pp. 268-74; Heyder, 216-26; Kampe, 180-92.

<sup>3</sup> On induction and recognition of similarity, see *Topics*, i. chap. 18, p. 108b, 7-9; vii. chap. 1, § 14, and chap. 8, § 1 (in these last similarity is viewed as being wider in scope than the basis of induction). That induction implies a complete enumeration, see *Anal. Pr.*, ii. chaps. 23, 24; *Anal. Post.*, ii. chap. 7, § 4. That induction even when complete is not demonstrative, see *Anal. Post.*, i. chap. 5.

<sup>4</sup> On this distinction see mainly *Anal. Post.*, ii. 13, where a very fine description of deductive and inductive proof occurs.

<sup>5</sup> Compare the passages above noted, and see the curious expression used in the discussion regarding the relation of universal and particular in *Anal. Pr.*, ii. 21, p. 67a, 23-24.

<sup>6</sup> *Anal. Post.*, ii. 5, p. 91b, 28, οὐδὲ γὰρ ὁ ἐν ἁγῶν ἰσὺς ἀποδείκνυσθαι, ἀλλ' ὁμῶς δηλῆσθαι.

<sup>7</sup> *De Part. Anim.*, iv. 2. Cf. Hamilton, *Lect.*, iv. p. 388, n. On *Anal. Post.*, ii. 14, see the valuable summary by Grote, i. pp. 268-69.

lies mainly in the matter, not in the form, of the process. For there are numerous hints in Aristotle respecting scientific procedure,<sup>1</sup> and, if we consider what is peculiar to modern views, we shall find that it consists mainly in the increased fullness and complexity of our fundamental scientific notions, a fullness and complexity resulting from long-continued scientific research. Our modern logic of induction has profited mainly by the general advance of scientific method, and tends to increase as these methods, by constant contact with facts, become more refined and accurate. The additional cautions or limitations which we now introduce into our statement of the principles of inductive research concern not so much the form of inductive proof as the character and modes of obtaining evidence which is to satisfy the canons or rules of proof. Such limitations become apparent only through actual scientific progress, not by analysis of the form of scientific proof.

18. For Aristotle, as has been above said, proof is essentially syllogistic or deductive in character. Not every syllogism is an apodictic proof, but all proof is syllogistic. For proof or adequate knowledge is reference of effects to their causes, and the cause is the general element, τὸ καθόλου, which forms the middle term in apodictic proof. Now proof by means of the cause or reason implies the existence of the cause; the inquiry why a thing is is useless unless we know or assume that the thing is. If it exists, then the cause or reason of its so existing is that which gives it a definite character or position; it is, in technical phraseology, the form of the thing. But the form of the thing, regarded apart from the material, accidental element essential to its concrete existence, is that which we express in a definition. Proof and definition are thus most closely connected. The *terminus* to which proof tends, not realized in all cases of proof but certainly in the most perfect, is the definition, and, besides, if we closely examine proof, and find that ultimately we can force back the chain of middle terms up to certain ultimate, primary universals, disclosed by *vois*, and that the nature of these primary universals is stated in their definition, we see further that definition is connected with proof as the *terminus* from which proof starts. The exposition of definition is thus the crowning portion of Aristotle's theory of apodictic method.<sup>2</sup> In it we have brought into close, though not explicit, relation, the fundamental notions on which his logic rests,—the notions of the essence, universal, genus and specific difference. Definition, as concerned with that which is involved in demonstration, the ground or reason, is in cases where the reason and consequent are separable the sum of the demonstration; it is the compressed statement of the connexion between a subject and the attribute demonstrated of it, *i.e.*, in a syllogism of the first figure, the major term.<sup>3</sup> Frequently a definition merely states the demonstrated attribute in relation to its subject, without indicating the rational link.<sup>4</sup> Such definitions, however, are defective, just as the conclusion of a syllogism, if taken *per se* is defective.<sup>5</sup> A genuine definition is the statement of the essence, which in mediated notions is the cause or middle term of the demonstration, in immediate notions is directly assumed.<sup>6</sup> A merely nominal definition or explanation of what a name signifies is but a preparatory stadium in the progress towards real, genetic definition.

Definition, then, like demonstration, rests on the essential or rational ground, the notion of the thing. The rational ground or notion has its empirical aspect; it determines a class, and thus, just as in demonstration we may have forms of reasoning based primarily on the empirical details, so in framing definitions we may proceed from the empirical class, and may formulate rules for defining which bear special reference to the genus or body of individuals. In such procedure there is always involved the general idea of the essence or notion as the determining universal, and without this general idea the subsidiary methods, induction and division, do not yield scientific definition.

To frame a definition, then, *i.e.*, to discover the elements whose combination as an essential unity makes up the notion of the things defined, we select the predicates belonging to the things in question,

but also attaching to other species of the same genus. The combination of such predicates which is not found in any other species, which is, therefore, reciprocable with the essence or form of the species, is its definition. The definition, therefore, contains the genus and the specific attribute (or combination of attributes). Of these elements, the genus is the least important; the truly essential factor is the specific difference, and, in order that our definition should be ultimate, we must follow out the line of specific difference by which a genus may be divided until we reach a final, irreducible characteristic or group of characteristics, constituting a lowest species (or natural kind, if one were to employ a term made current by J. S. Mill). The systematic following out of the specific differences is logical division; the critical comparison of points of similarity in species of the same genus, so as to obtain a higher generality, has no special title accorded to it, but it resembles the Socratic and Platonic induction (*αναγωγή*). Division proceeds on the oppositions actually found in nature; and, though, doubtless, the division by dichotomy has formal advantages, it has not, as a process of real cognition, any supreme value. The negative as such is the inconceivable, and presents nothing for cognition.<sup>7</sup> And division is not dependent on exhaustive knowledge; it is not necessary that, in order to recognize A as distinct from B, we should know the whole universe of possible objects of cognition. A and B may be recognized as identical or distinct in essence, even though they at the same time possess distinct or identical accidental marks. Knowledge, in other words, turns upon the essential, not upon the numerical universal.<sup>8</sup> It is only useful, then, that in the systematic process of indicating the elements of definition, all must be included that concern the essence, that the order must be strictly from determining to determined (or from more abstract or general to more concrete or special), and finally that the enumeration be complete. The final division or species reached is the notion of the thing, and its expression is the definition.

19. The analytical researches thus manifest themselves as a real theory of knowledge and as forming an integral part of the Aristotelian system. Logical relations are throughout conditioned by the characteristics of the Aristotelian metaphysical conception, and the distinction of the formal or technical from the real in cognition has no place in them. No point is more frequently insisted on by Aristotle than the impossibility of deducing any scientific principles or results from the fundamental axiom of thought, the law of non-contradiction. In the Aristotelian system this axiom appears simply as the generalized expression for the peculiar characteristic of thought, its potentiality of truth or falsehood. Such potentiality accompanies thought throughout, and is the mark of its subjective character, but the actuality of thought is something quite distinct, and is only realized through the various processes whereby the world of fact is apprehended. Beyond a doubt knowledge has a general aspect; and there is thus possible a general theory of knowledge, but this is not to be regarded as merely a development from the fundamental axiom of thought. It is the general statement of what constitutes actual cognition, and thus refers on the one hand to the ultimate properties of that which is to be known, on the other hand to the qualities of knowledge as a subjective, though not the less real, fact. For to Aristotle subjective has not the sense which it may be said to have assumed in modern logic, mainly through the Kantian analysis. The activity of thought which realizes itself in the consciousness of the individual is not a mere formal process of apprehension, mirroring or depicting reality that is totally distinct from it. It is a reality, one aspect or phase of the total sum of things, and its development is a real process correlative with the development inherent in things as a whole.

At the same time it is impossible to overlook the difficulties which attach to the Aristotelian conception, and the consequent obscurities or perplexities in his logical researches. To remain always true to the fundamental conception of thought as one factor or phase in things, to trace its forms in such a mode as never to lose sight of its essential correlation to the development of reality, is in itself the hardest task for any thinker, and presupposes a more completed metaphysic than is to be found in Aristotle. Some of these difficulties may be briefly noted, as they form the turning points of certain later doctrines. The judgment or proposition is taken as the initial, the simplest phase of the activity of thought, and so as having the simplest relation to things. But the distinctions of things which are subjectively seized in the judgment are too much regarded as given facts, and Aristotle is thus involved in a difficulty respecting the import, the truth or falsity, of the judgment. The presence of this difficulty is specially discernible when he attempts to deal with the temporal reference in the judgment, with the doctrine of opposition, and with the nature of modality. Thus, he notes that the verb, the essential part of the predicate, has a

<sup>1</sup> See, for example, the discussions on *Topics*, I. 17-18; II. 10-11, on similarity; in the *Post. Anal.*, I. 1-2, on deductive and inductive methods; in *Post. Anal.*, II. 1-3, on the formation of definition; and in *Ps. A. Anal.*, II. 12, 14-18, on the relation of cause and effect.

<sup>2</sup> It was not soon necessary here to consider in detail the peculiarities of apodictic proof, as we had out in the first book of the *Post. Anal.*, nor to deal with the various cases regarding definition and proof in the first chapters of the second book. The nature of these different chapters can be readily summarized. If definition is *κατὰ φύσιν*, as a finished result, it seems to stand in no relation to proof, and is left to be dealt with in the *Metaphysics*, as we see from

the application in the *Post. Anal.* of the definition of the soul and of the definition of the essence of the soul to the definition of the soul and of the essence of the soul. The definition of the soul is not a finished result, but a process, and is only discoverable when there is the recognized distinction of fact and reason of the fact. We must consider definition in the same manner as being involved in and resulting from the genesis of scientific knowledge.

<sup>3</sup> ἀποδεικτικὴ θέσις διατηροῦσα, *Anal. Post.*, I. 8, p. 75b, 31.

<sup>4</sup> συμπαρασπῆς τι ἀποδεικτικῶς, *ibid.*

<sup>5</sup> *De Anima*, II. 2, p. 413a, 18 sq.

<sup>6</sup> ὅτι δὲ τὸν ἄριστον ὁρισμὸν θέσις ἐστὶ τοῦ τι εἶναι ἀναπόδεικτον.

<sup>7</sup> Just as the *ὁμοῖα ἀπόδεικτον* is said to have no significance save as the summary of a proposition, while a negative proposition has significance only in regard to the corresponding positive.

<sup>8</sup> The reference is to a theory advanced by Spensippus; see Prantl, I. 85. Aristotle here touches on a logical problem which has troubled many logicians. It is the same difficulty that arises when the question of plurality of causes is considered.

temporal significance, but he also notes that in universal judgments there is no reference to any specific time, and also that the copula, the verb *is*, has no existential meaning. He is thus driven to the enunciation of a view, common among recent logicians, that the judgment is a reflective or critical act, pronouncing on the truth or falsity of a contemplated separation or conjunction of facts, while, on the other hand, the very contemplation of conjunction or separation has appeared as the essence of the judgment. So, in dealing with opposition, he distinguishes contradictories from contraries, and is inclined to refer the second to the given nature of facts, wherein extreme oppositions of members falling under the same genus are presented. Modality, likewise, he treats confusedly, for the assignment of the modal relations to the predicate does not sufficiently determine their place in a theory of judgment, nor explain the relation in which they stand to the judgment as the simplest activity of thought.

Further, in dealing with the quantity of judgments, Aristotle is perplexed by his own theory of what constitutes generality. He is compelled to throw together universal judgments of a totally distinct kind,—empirical and rational, as one may call them,—and though the underlying view that empirical universality is the expression of, and is dependent on, rational connexion is made sufficiently clear in the doctrine of proof, it is not carried out to its consequences in the doctrine of judgment. Finally, to note only the crowning difficulty, the theory of proof and of definition turns upon the nature of the essential connexion of attributes in a subject, but the explanation of essence is precisely the *locus in the system*. Indications of a theory of essence are not wanting, but it does not seem possible so to unite them as to form a consistent whole. The greatest obscurity still hangs over the fundamental part of the system, the nature of the *πρώτα* which are apprehended by *νοεῖς*, of the specific relation of attributes *καθ' αὐτά* to their subjects, and of the *ἰδία ἀρχαί* from which particular sciences start. That the *πρώτα* are *ἐκείνα*, so frequently adduced as integral parts of proof, are analytical judgments<sup>1</sup> cannot be accepted without such qualifications as to render the use of such a term misleading; but what their precise nature is remains in the Aristotelian system undetermined.

#### *Logic from Aristotle to Bacon and Descartes.*

20. The long history of philosophic thought from Aristotle to the beginning of the modern period furnishes no new conception of logic so complete and methodical as to require detailed treatment, but exhibits alterations in special doctrines, additions, and new points of view numerous enough to account for a certain radical change in the mode of regarding logic which is, for our present purpose, the only interesting feature. This change may perhaps be expressed not inaccurately as the tendency towards formalizing logic. Gradually logical researches came to have their boundaries extended in one way by the introduction of new matter, and narrowed in another by restriction of logical consideration to one special aspect of knowledge. Much in the history of this movement still remains in obscurity, but the general result is sufficiently clear. The periods into which the historical development of logic throughout this long interval may be naturally divided, with their main characteristics, are the following. (1) *The Peripatetic School*, represented by Theophrastus and Eudemos, following in the main the Aristotelian tradition, but deviating in certain fundamental respects, and on the whole treating the matter of logical research as though it were separate from and independent of the theory of knowledge as a whole. To this school is due the distinct recognition of the hypothetical and disjunctive proposition and syllogism, and the more complete enumeration of the possible valid modes of categorical reasoning. In both cases the additions are made to turn upon purely formal considerations. The hypothetical and disjunctive judgments are treated as given varieties, to be discerned in ordinary language and expression, not as resting upon any fundamentally distinct principle or activity of thought.<sup>2</sup> The addition of five indirect moods to those recognized by Aristotle as belonging to the first figure proceeds on the purely formal ground of difference in position of the middle term in the two premisses. (2) *The Epicurean and Stoic Logics*. Of these the Epicurean presents no points of interest. The Stoic logic, on the other hand, is the first example of a purely formal doctrine based on and associated with a thoroughly empirical theory of cognition. In essence the Stoic doctrine is identical with that of Antisthenes, above noted, and it is interesting to observe that, under the purely nominalist theory, logic becomes almost identical with the doctrine of expression, or rhetoric. The theory of naming, and that of the

conjunction of names in propositions, are the fundamental portions of the body of logic. Naturally the Stoic logicians tended to increase the bulk of logic by introducing numerous distinctions of language, and by signalizing varieties of judgment dependent on varieties of verbal expression. (3) *The reception of Logic among the Romans*. Here there must be distinguished the quasi-rhetorical logic, such as is found in Cicero, which is altogether Stoic in character, and the Aristotelian logic, as developed by Boetius with the additions of the later commentators. In Boetius one notes specially the technical or formal character of the treatment, which was of special importance historically, from the fact that the earlier scholastic writers derived their main knowledge of logic from certain of the treatises of Boetius. (4) *The Scholastic Logic*. On the details of the scholastic logic it is not necessary to enter, but there must be noted the following points as of more than determining what may well be called the current conception of the Aristotelian logic in modern times. The earlier scholastics, in possession of but few of Aristotle's writings, added nothing of importance to the body of logical researches, and the permanent subject of discussion, the nature of universals, did not, through any of its solutions, affect the treatment of logical doctrines. The introduction of the body of the Aristotelian writings was contemporaneous with the introduction of the Arab writings and commentaries into western Europe, and there grew up therewith a more developed treatment of what may be called the psychological element of logic. The logic of the later scholastics is characterized by two points of interest, historically unconnected, but having a natural affinity,—the one, the introduction of an immense mass of subtle distinctions, mainly verbal, making up the body of the *Pars Logica*, the other, the influence of the nominalist conception of thought.<sup>3</sup> The peculiarity of the nominalist view is the severance of immediate apprehension from discursive thought, the assignment of all matter of knowledge to the one, and of all form to the other. But form, under this conception of discursive thought, can be found only in the generalizing function of signs or names; accordingly the fundamental processes of logical thought are regarded as so many modes of application of names. The later nominalist logicians were thus naturally led to the expenditure of immense subtlety and diligence on the thorny problems of the *Pars Logica*, while at the same time the peculiar inner difficulty of the theory became apparent as its consequences were worked out. (5) *The Reaction against Aristotelianism and the Humanist Modification of Logic*. Little of positive value for logical theory is offered by the numerous works representing this stage of historical development. Valla, Agrius, and Vives, with much good criticism in general spirit and detail, present a rhetorical-grammatical logic that resembles most closely Cicero's eclectic reproduction of Stoicism. Ramus, the only logician of the period with historic renown, contributes really nothing to the history of logic, his innovations consisting mainly in the omission of the most valuable portions of the genuine Aristotelic logic, the insertion of practical and interesting examples, and finally rearrangement or redistribution of the heads under which logical doctrine was expounded. The Ramist school, most numerous and flourishing, produced no logical work of the first importance.<sup>4</sup>

The net result of this whole period was the severance of a certain body of doctrine, formal in character (the theory of second intentions), from theory of knowledge generally, and from all the concrete sciences. The boundaries and even the functions of this doctrine remained unaltered, for difference regarding fundamental points of extra-logical theory led to difference in mode of treatment, as well as to difference in conceptions of the end and value of logic.

#### *Logic of Bacon and Descartes.*

21. Modern reform of logic, by which may be understood the attempt to place logical theory in a more close and living relation to actual scientific method, begins with Bacon and Descartes. To both the scholastic logic presented itself as the essence of a thoroughly false and futile method of knowledge. Neither had the acquaintance with the genuine Aristotelian system requisite in order to distinguish the elements of permanent value from the worthless accretions under which these had been buried, and, as a natural consequence, the views of both have a far closer resemblance to the Aristotelian doctrine than might be imagined from the attitude of opposition common to them. Both thinkers were animated by the spirit of reformation in science, and both emphasize the practical end of all speculation. For both, therefore, logic, which to neither is of high value, appeared to be a species of practical science, a generalizing statement of the mode in which intellect acquires new knowledge, in which the mind proceeds from known to unknown.<sup>5</sup> But such a conception of logic is, if the expression be permitted, formal; that is to say, the actual province of logic is not determined thereby, but awaits determination from

<sup>1</sup> As Zeller will have, see *Ph. d. Gr.* 3, 2, 191, n. doubtless Aristotle does define an essential attribute as being one contained in the subject or one of which the subject notion is an integral part, but this relation of entering into the definition is not to be identified rashly with the modern view of the analytical relation of subject and predicate.

<sup>2</sup> The nature of hypothetical inference and its laws are recognized with the greatest distinctness by Aristotle. From his theory of essence as causal nexus, any distinction of kind between an apodictic (categorical) syllogism and a hypothetical of the type contemplated by later logicians was impossible and needless.

<sup>3</sup> The fact of these is no doubt, as Prantl has laboured to prove, Byzantine in origin, but it still remains doubtful whence the Eastern logicians draw. The most probable source is the Stoic writings.

<sup>4</sup> See note C, p. 803.

<sup>5</sup> Comp. *Princip. Phil., Pref.; De Aug. Sc.*, bk. v chap. 1, 2.

the further idea of the nature of knowledge and the ultimate constitution of that which is to be known. When this point is reached, a radical divergence presents itself between the views of Descartes and Bacon, consequent on which appears a radically divergent statement of the main processes and methods of logical theory.

To Descartes the ideal of cognition is the mathematical, that in which from assured and distinct data we proceed by strict sequence of proof to determine accurately and completely the nature of complex phenomena. Such an ideal, extended so as to embrace knowledge as a whole, dominates the whole of the Cartesian speculation, and, as in the case of the Socratic doctrine of knowledge, is the ground of the Cartesian doubt. Perfect certainty, i.e., clearness and distinctness of principles, logical consecutiveness of deduction from them, and exhaustive enumeration of details—such are the characteristics of completed knowledge. There follow naturally therefrom the main processes of knowledge:—*intuition*, by which the simple data and axioms are apprehended; *induction*, or exhaustive enumeration of the elementary factors of any phenomenon; *deduction*, or determination of the complex as the necessary result of the combination of simple factors. To the processes of induction and deduction, when viewed more generally, the titles analysis and synthesis may be given.<sup>1</sup> On other portions of logical theory Descartes does not enter, and the text-books of the Cartesian school, even the celebrated Port Royal logic, do little more than expound with some freshness such of the older material as seemed capable of harmonizing with the new conception.

Two things only require note in respect to the Cartesian logic, apart from its freshness and completeness; the one is the obscurity which hangs over the nature of intuition; the other is the step in advance of the scholastic logic effected in the assimilation of deduction to synthesis. As regards the first, the criteria laid down by Descartes, viz., clearness and distinctness, are unsatisfactory and ambiguous. It is evident that he implied under these clear and distinct recognition of *necessity* in the data or principles, but the nature of this necessity is never made clear.<sup>2</sup> As regards the second, it was of importance to signalize, as against the scholastic view, that the universal in thought or reasoning was not only of the nature of the class notion, that genera and species were not the ultimate universals, but were themselves secondary products, formed by reasoning, and based upon essential connexion of facts. In this Descartes was but returning to the genuine Aristotelian doctrine, but his view has all the advantage derived from a truer and more scientific conception of what these connexions in nature really are.

22. What is peculiar in the logic of Bacon springs likewise from the peculiarities of the underlying conception of nature. The inductive method, expounded in the *Novum Organum*, is, however, only part of the Baconian logic, and, since it is commonly regarded as being the whole, a brief statement of what Bacon included under logic may here be given.

Viewing logic as the doctrine which deals with the use and object of the intellectual faculties, Bacon divides it (in this approximating somewhat to the extended division of the Stoic logicians) into (1) the art of inquiry or invention, (2) the art of examination or judgment, (3) the art of memory, and (4) the art of elocution or tradition. The third and fourth divisions are unimportant; the first and second might be called respectively the theory of the acquisition of knowledge and the theory of evidence or proof. The art of inquiry is subdivided into the art of the discovery of arts and the art of the discovery of arguments. The second of these Bacon regards as identical with the *Topics* of the Greek and Roman dialectic, and therefore as of comparatively slight value. Of the first there are two main branches:—(A) *Experientia Literata* and (B) *Interpretatio Naturæ*. The art of judgment has two subdivisions:—the examination of methods of reasoning—induction and syllogism—which resembles the older analytic; and the examination of errors of reasoning—whether these be sophistical, i.e., the logical fallacies of the older doctrine, or errors of interpretation to be removed by careful criticism of scientific terms, or arising from erroneous tendencies of the mind (the doctrine of *idola*)—which resembles the older treatment of *Elenchi*.

The peculiarity of the Baconian logic, then, must be sought in the processes included under the art of discovering arts or knowledge. Among these the syllogism is not included. It is a process with no practical utility; it involves premises of which the truth is simply assumed, and consequently its conclusions can have no validity beyond that of the premises; it affects to determine the particular from the general, but in fact nature is much more subtle than intellect, and our generalizations, which are but partial abstractions, are quite inadequate to afford exhaustive knowledge of the particular; it throws no light upon the essential part of cognition as a process

information, viz., the method by which we are to obtain our notions of things, and judgments based on these notions. Moreover, the deductive or syllogistic procedure favours and encourages the tendency to rash generalization, to the formulation of a universal axiom from few particulars, and to the uncritical acceptance of experience. If syllogism exist at all, there must be a prior process, that of generalizing by rigid and accurate methods from experience itself. Syllogism is not entirely worthless. It is of particular service in some branches of science (e.g., the mathematical), and generally may be employed so soon as the principles of a science are well established; but it is a subordinate and secondary method.

The art of discovery, then, is the method of generalizing from experience. What this method shall be depends entirely on the thinker's conception of experience. Now Bacon's conception is perfectly definite. Observation presents to us complex natures which are the results of simpler, more general forms or causes. From the complex phenomena these forms are to be sifted out by a methodical process of analysis and experiment. A general proposition is one stating the connexion between complex natures and their simple forms or causes; it is, therefore, the result of a graduated process. No doubt there may be generalizations based only on an ingenious comparison of the complex phenomena as they are presented to us; such a process Bacon calls *Experientia Literata*, and the maxims recommended for it much resemble the ordinary methods of experiment, but truly scientific knowledge is only to be obtained by the complete inductive method. The characteristics of this inductive method follow at once from the nature of the object in view. The form which is sought can be detected only by examination of cases in which the given complex effect is present, in which it is absent, and in which it appears in different degrees or amounts. By a critical comparison of these cases we may be able to detect, and, were the enumeration exhaustive, we must infallibly detect, by process of exclusion or elimination, a phenomenon constantly present when the effect is present, absent whenever the effect is absent, and varying in degree with the effect. Such a phenomenon would be the *form* in question,—the cause of the given fact or attribute. Exhaustive enumeration is, of course, an ideal, and therefore the method of exclusion can never be perfectly carried out, but all additional aids have significance only as supplying in part the place of exhaustive enumeration. We may, on the basis of a wide examination, frame a first generalization (*first vintage* as Bacon metaphorically calls it), and proceed to test its correctness by carrying out the critical comparison with it in view. Or we may, under the guidance of our leading principle, take advantage of certain typical cases presented by nature, or force cases by experiment in such a way as to supersede the enumeration. There are *prerogative* instances, critical phenomena, helpful in discovery of the cause of a phenomenon. Of other *admiracula*, or aids to induction, only the titles are given by Bacon, and it would be hazardous to conjecture as to their significance.<sup>3</sup>

The Baconian logic, then, or at least what is peculiar to it, is thoroughly conditioned by the peculiarities of the Baconian metaphysics or conception of nature and natural processes. As to the novelty of the logic, this to us does not appear to lie in the mere fact that stress is laid upon induction, nor do we think it correct to assign to Bacon the introduction of the theory of induction as an integral portion of logic. But it consists in the new view taken of what constitutes the universal in thought, a view which may be inadequate, but which colours and affects every process of thought, and therefore every portion of logical theory. It is but a consequence of Bacon's narrow view of the essence of syllogism that he should set induction in opposition to deduction, and regard syllogism as of service only for communication of knowledge. His inductive methods are throughout syllogistic in this respect, that they like all processes of thought involve the combination of universal and particular. Experience is interpreted, that is to say, viewed under the light of a general idea or notion.

#### Logic on the Basis of Psychological Empiricism.

Locke, Hume, Mill, Comillac.

23. The universal element in thought which is recognized by Bacon as present received from him no special treatment. His theory of the nature of knowledge offered no explanation of the origin, significance, and validity of the notions involved in inductive procedure. The *Essay on the Human Understanding*, which carries out in the domain of inner experience the practical tendency of the Baconian method, supplied from the point of view of individualism the metaphysical theory common to both, a certain psychological theory of the universal element in knowledge, and thereby afforded a new foundation for logical doctrines. The *Essay* contains, in an unsystematic fashion, much that bears directly on logic (e.g., the whole discussion on names, the classification of the signification of

<sup>1</sup> See *Regule ad directionem ingenii*, Nos. 2, 7 and especially 7. The celebrated rules of speculation (*De Methodo*) are only a more popular statement of the same processes.

<sup>2</sup> His ultimate standard is, no doubt, necessity for a thinking subject. Whatever is so connected with the existence of the thinking being that without it this existence is incomprehensible is necessary. But to apply this ideal to any proposition save the first, the *Cogito ergo sum*, is for Descartes the fundamental difficulty of his philosophy.

<sup>3</sup> *Nov. Org.*, II, 21. In addition to prerogative instances there are mentioned supports of induction; rectification of induction; variation of the investigation according to the nature of the subject; prerogative natures; limits of investigation; application to practice; preparations for investigation; ascending and descending series of axioms.

judgments, the criticism of syllogistic argument), but of more importance than these detached and direct portions is the general principle which underlies the whole view of human knowledge. This principle is briefly that of psychological genesis. All the complex facts of knowledge are regarded as mechanical compounds due to the coherence of simple data, the facts of inner and outer sense. The method of Locke is that which underlies and determines all the logical work of one very important school of logicians.

It is not needful to enter into details of Locke's own contributions to the foundation of logic. But it may be pointed out that from his position there were two possible lines of development. In his view the primitive impressions, the facts of inner and outer sense, were in themselves primitive facts of cognition; they were cognitions (it is the very essence of Locke's method to identify a simple impression of sense with the knowledge of a simple sense fact). The processes of abstraction, comparison, i.e., judging and reasoning, were exercised upon their data, and these products were, in consequence, of a secondary and, so to speak, artificial character. It was natural that a thinker who identified impression of sense with knowledge of a sense fact should maintain that the secondary formations of thought (general ideas, general propositions, syllogism) were not indispensable for cognition; that we could and did reason from particulars to particulars. At the same time Locke admitted the secondary processes as having actual existence, and in one important case (that of the judgment of coexistence, with which may be taken the idea of substance and of real relation) seemed to allow that in judgment something was added to the primitive data. It was possible, then, for development from Locke's position to proceed either by offering an explanation of the added elements, which should be in stricter harmony with the fundamental doctrine of psychological genesis, or by throwing them entirely out of account and concentrating attention on the primitive data as the only materials of cognition. The first is the line taken by Hume, which finds its logical completion in Mill; the second is the line taken by Condillac.

Hume has an easy task so long as he merely subjects Locke's position to negative criticism; for the added elements, the ideas of substance, relation, cause, &c., are clearly inept and defenceless when the facts to be linked by them are already contemplated as so many completed, isolated cognitions. But where connectedness of cognition is in question, and where some explanation is demanded of the relations which seem to supply the universal rule in thinking, Hume's task is not so simple, and his final answer that these relations are psychological growths or products of association is neither satisfactory in itself nor quite in keeping with other portions of his doctrine. In Hume, however, we find the first thorough-going attempt to construct a theory of knowledge on the basis of psychological empiricism or individualism, and the first contributions to a doctrine of inductive proof as portion of this more comprehensive theory. Briefly, so far as logic is concerned, Hume offers as explanation of the universal in thought association of ideas, but does not treat of logic specially or in detail.

The complete statement of the theory of knowledge from the psychological point of view is that contained in Mill's *System of Logic*.

The aim of that work is the exposition of the theory of knowledge. Now knowledge, the term being taken in a wide sense, is characterized by one quality mainly, viz., evidentiary force. For every item entering into the sum of our beliefs at any moment, immediate perception being discounted, there may be reasons advanced, adequate or inadequate. The exposition of the relations between beliefs and their evidence or ground is logic, and logic is thus in one sense formal, inasmuch as the relations of evidence and belief are general, not dependent on the special nature of the facts believed, and in another sense real, in that knowledge is conceivable only in strictest relation to the things known.

Now, the exposition of the general nature of grounds of belief is in fact identical with a theory of the universal element in thought or cognition, and this theory is the essential portion of Mill's logic. It being assumed that the facts with which knowledge is concerned are minds, bodies, states of consciousness, and the relations (coexistence, sequence, similarity) among these states, and that propositions express, therefore, existence, coexistence, sequence, or resemblance, on what is based any inference going beyond a present perception? The propositions which make up cognition, strictly so called, are not mere expressions of momentary states; they are expressions of belief regarding the more or less constant relations of facts. They are, in fact, conclusions. The theory of proposition and of reasoning is one. On what, then, do such conclusions rest?

The warrant for any conclusion based upon experience, and referring to experience itself, can be found only in experience or in some principle furnished by experience. It may be shown that evidence for a conclusion is adequate if we can compare this evidence with the kind of evidence on which a wider conclusion, frequently or constantly verified, rests. This comparison of particular evidence with more general evidence is the preliminary

answer furnished by Mill. But what is the general evidence referred to, and what is the principle founded on it? The general evidence is the repeated experience of constancy of connexion among groups of phenomena, and the principle founded on it is that of the existence of uniformity or rather of uniformities in nature. The evidence and the principle are purely psychological in character; that is to say, repeated experience, beginning with familiar cases and extending itself as time goes on, produces, by the natural laws of association, an assured belief that phenomena as a whole, or at least in the main, are connected together in constant, uniform, invariable modes. Such a belief, once established, serves as an ultimate criterion of proof, and as an index for research. We proceed in our investigations in the light of this principle, and the tests by which we estimate the validity of evidence for any particular inference as to uniformity are generalized statements deducible from it. So soon as our evidence is of such a character that, in the case before us, either the inference of uniformity is warranted or the general principle must be held not to apply to this particular case, we have proof as cogent as experience can afford.

The universal in knowledge, then, is this naturally formed assumption regarding the course of nature. The logic of knowledge is the exposition of the modes in which evidence is obtained, of the tests by which its validity is estimated, and of the forms in which evidence and conclusion are connected.

The characteristic features of the subordinate processes of proof rest at once deducible from this fundamental view. For if the simplest form of inference be, psychologically, the transition effected by association from one particular case to another resembling it, and if the essence of proof consist in comparison of the evidence for any one conclusion with the type of evidence for the general assumption regarding nature (or at least a wider portion of nature), it is evident that syllogism, in the ordinary acceptance of the term (in which it implies a concrete general proposition, a particular subsumed thereunder, and a conclusion), is neither a primitive form of inference nor a valid mode of proof. Doubtless we do in reasoning employ general propositions in order to express the determination of some particulars belonging to the same class, but the general proposition is itself a conclusion, resting on evidence of the kind above described, and the essence of syllogistic reasoning is not the subsumption of a particular under a general in which it is included, but the expression of belief that the evidence for the general proposition is adequate to cover all the particular cases, including those which have not been taken into account in formulating it. The major premiss of a syllogism is the record of a previous induction, and the syllogistic process, bringing forward a new case, is a valuable method for testing the adequacy of the previous generalization. As to generalization itself, the basis is evidently to be sought in experience, apprehended by observation and experiment. Did experience present to us isolated phenomena, i.e., phenomena so arranged that enumeration of the elementary constituents, whether antecedents or consequents, were possible, then our inductive procedure must be regulated by those canons or axioms which express the kind of evidence already referred to as establishing uniformity. These canons or axioms, however, are, like the Baconian method of exclusion, tests for an ideally perfect experience, and they, therefore, only lie in the background of actual scientific procedure, which has to employ other processes, both of inference and of proof. For, if we can in no way obtain more than a knowledge of the coexistence of facts, we are unable to bring our evidence into conformity with the inductive canons, save in the ideal instance in which absolutely exhaustive experience both of positive and negative cases is possible. Inferences as to law or uniformity of coexistence must here be based on numerical calculation of probability, and the conclusions present themselves in the peculiar numerical form appropriate to propositions of probability. Further, if the phenomena under investigation be complex, so that the canons of neither observation nor experiment are immediately applicable, the process of investigation must of necessity be the combined method of analysis and synthesis: analysis, aided by hypothetical conjecture, formulating such general laws of elementary factors as are known or presumed to exist in the case in question; synthesis, combining these laws and calculating with greater or less numerical exactness, according to the nature of the matter, the probable combined effect,—the whole tested by critical comparison of the calculated result with the actual phenomena. Here, as one can see, syllogistic procedure appears in its true scientific aspect as the form of thought by which we pass from the simple to the more complex, from the elementary essence or cause to the complex accident or effect. The elementary causes, no doubt, have no more cogent evidence than that which can be afforded by experience viewed in the light of our psychological assumption of uniformities; nevertheless the whole procedure of scientific investigation is recognized as being essentially of the type sketched in somewhat imperfect outline by Aristotle.

So far, then, as the logic of Mill is concerned, and apart from the undeniable richness and completeness of knowledge with which the various processes are treated, we note but one fundamentally new feature, namely, the explanation offered of the universal element in

sphere of apperception. According to this view the whole province of knowledge is excluded from logic, and it is assumed that knowledge is somehow given; mechanically, without the co-operation of processes, if not identical with, yet strongly resembling, those recognized as logical. Herbart does not succeed in vindicating an independent place for a purely formal logic.

*The Kantian Logic.*

27. The critical method, which has so influenced general philosophy that all later speculation refers more or less directly to it, has at the same time profoundly modified all later conceptions of the sphere and method of logic. From the Kantian philosophy there spring directly the three most important modern doctrines of logical theory,—that which, with many variations in detail, regards logic as a purely formal science, the science of the laws of thought or of the laws under which thought as such operates, and of the forms into which thought as such develops; that which, likewise with many variations, unites logical doctrines with a more general theory of knowledge; and finally that which identifies both logic in the narrower sense and theory of knowledge with an all-comprehensive metaphysic.

It is matter of history that the critical system was developed mainly from the basis of the Leibnitzian logical and metaphysical theories, and it is likewise matter of history that Kant, even in the speculative work which was to so large an extent antagonistic to these theories, remained under the influence of some of their cardinal positions.<sup>1</sup> In particular the view of logical thought as purely discursive, analytic in character, a view never by Kant harmonized with his general system, is a relic, most significant for the development of his logic, from the Wolffian reproduction of Leibnitz's philosophy. This historic basis is not to be lost sight of in attempting to acquire a clear idea of the special place and function assigned by Kant to logical theory.

But a brief reference to the general result of the critical philosophy will suffice to introduce the more special treatment of the Kantian logic. Knowledge, or real cognition, which is analysed in the *Kritik* in reference to its origin and validity, appears, when subjectively regarded, as a compound of intuition and thought, of sense and understanding. The isolated data of sense experience do not in themselves form parts of cognition, but are only cognized when related to the unity of the conscious subject, when the subject, as it may be put, has consciousness of them. This reflex act, resembling in some respects Leibnitz's apperception, or process of uniting in consciousness, is an act *sui generis*, not to be mechanically conceived or explained. Only through its means do representations become cognitions. The forms in which the synthetic act of understanding is carried out are, as opposed to the intuitive data on which they are exercised, discursive or logical in character. Essentially they are judgments: all acts of understanding are judgments, and, as judgments, they imply a general element with which the particular of sense is combined, and in the light of which the particular becomes intelligible. In ultimate analysis it appears that no particular, whatever be its enjoin'd character, can become an intelligible fact, save when determined through some specific act of understanding, through combination with some specific notion or general element. Combination of particular and general is thus the very essence of understanding, the mark of knowledge as such. In every item of cognition the same elements may be discerned as necessarily present. The consideration of the ultimate modes of intellectualization, of the series of acts by which understanding subsumes the particular, draws the particular into the unity of cognition, may be called in a large sense logic. If the consideration be specially directed to the mode in which, by means of this combination, knowledge arises, and therefore include discussion of the wide problem regarding the relation between understanding and objectivity in general (the matter of knowledge taken generally), the special title transcendental logic may be used. But if, concentrating attention solely on the kind of operation implied in understanding, we endeavour to lay out fully the modes in which understanding proceeds in the construction of knowledge, making abstraction of all inquiries regarding the origin, worth, significance of knowledge itself, the consideration is of a more general character, and may receive the title of general logic.<sup>2</sup>

The understanding, then, like everything else, works according to laws, the laws of its own nature. If we abstract from all that may characterize the matter considered, and take into account solely the laws according to which understanding must act, we may construct a purely formal doctrine, a theory which is rational both in matter and in form, for the matter consists of the laws of reason, and the form is prescribed by the very nature of reason,—a demonstrative theory, for nothing can enter therein which cannot be shown to have its ground in reason,—a completed theory; for although the matter of thought is infinite and infinitely varied, the modes in which the understanding must operate if unity of

cognition is to result, are finite and capable of exhaustive statement,—and a theory developed from its own basis, standing in no need of psychology or metaphysics, but deducible from the mere idea of understanding as that which introduces unity into representations, whether given (empirical) or *a priori* (pure).

Were this the only determination of the province of logic given by Kant, the question which at once arises as to the possibility of any such independent doctrine would receive an easy solution. For it is evident that logic, as a theory of the form of thought, could consist only of a portion of the more general doctrine, by whatever title that be known, in which the nature of understanding as synthetic activity is unfolded. The distinction on which Kant lays stress between matter and form, a distinction employed by all subsequent writers of his school, is ambiguous and misleading. If by matter be meant the particular characteristics of the things thought about, in which sense we might speak of judgments of physical, chemical, grammatical matter, and soon, then to say that logic does not take this into account is perfectly correct. If logic be a philosophic discipline at all, a theory in any way concerned with thinking, it is at once evident that it can in no way deal with the specialities of any particular science. But this of itself, the distinction between matter and form is by no means identical with another, lying in the background, and too frequently confused with the latter,—the distinction of understanding as a faculty *per se* with its own laws, deducible from its mere notion, and understanding as the concrete real act of thinking. What Kant calls the mere idea of understanding, and what in other writers of his school appears as a definition of thought, is really nothing but a reference to what has presented itself in the wider inquiries of the *Kritik*—to the complex nature of the synthetic activity of understanding. Kant himself never attempts to deduce from the notion of understanding the varied characteristics of logical forms, and his followers, e.g., Hamilton, when they are consistently start from concepts as expressing the bare notion of thought, and regard all other forms of thought as combinations of concepts.

But Kant does introduce another element into his treatment of the province of logic, one not original to him, but of the utmost importance for later developments from his point of view. He inquires what kind of relations among the elements of thought can form the matter of logical treatment, and defines these as two in number: (1) formal consequence, (2) non-contradictoriness. By formal consequence we are to understand the relation between a conclusion and its premises, no inquiry being raised as to the truth or validity of the premises. By non-contradictoriness we are to understand that, logically, notions, judgments, or reasonings can be subjected to treatment only in regard to the absence of explicit contradiction among the factors entering into them. Thought, which introduces unity and system into experience, must certainly introduce formal consequence and preserve analytic truth or coherency. Formal logic, then, treats only of these formal qualities of all products of thought.<sup>3</sup>

The detailed treatment of logic, so far as that can be gathered from the very brief summary (*Logic, Works*, iii. 29-316), shows with the utmost clearness how impossible it was for Kant to deduce the forms and relations of thought from the bare notion of understanding, even when coupled with the principles of forced consistency and consequence. Assuming that understanding is the discursive faculty, the faculty of cognizing the many particulars through the one concept or notion, Kant deals first with concepts (Begriffe) as general or discursive representations. He is careful to avoid an error into which many of his followers have fallen, that of regarding Begriffe in a mechanical fashion as a specific kind of Vorstellung distinguished only by containing a few of the marks making up the single intuitions. He rightly notes that cognition proceeds by subsuming the particulars under the common element contained in them, and that the generality of the concept thus rests upon the relation in which it stands, as reflective ground of cognition, to the particulars. The characteristics of concepts, as possessing extent and content, are treated briefly, after the fashion familiar in the more detailed logics of his school. It is, however, when the doctrine of judgment is reached that the difficulties of his position appear with greatest distinctness. Judgment is defined "as the representation of unity in the consciousness of distinct representations, or the representation of the relation of

<sup>1</sup> Two at least of the followers of Kant have worked out the system of logic from this point of view, the one, Twisten, in his *Logik, metaphysisch und empirisch* (1829), the other, the late Professor Mamsel, in his *Prolegomena ad Logicam*, Mamsel recognizing the distinction between the two modes of determining formal logic, adopts the second, and is therefore led, in consistency, to denote logic, not as the science of the laws and forms of thought, but as the science treating of formal thought, or of the formal elements in the forms of thought. In other words he recognizes that the statement of the forms of thought must be introduced into logic *ab extra*, from psychology or what not, and that logic, accepting these, has to consider the formal element (non-contradictoriness) as given. It is well to have the doctrine brought thus to its ultimate issue, for it is then apparent that there is no independent science called logic, but simply one comprehensive precept, which may be called logical, viz., avoid contradictoriness in thought. Illustrations of the ways in which contradictoriness manifests itself may be offered, and a useful logical praxis may thus be afforded, but the *p* do not make up a science or theory.

<sup>2</sup> See article *KANT*, vol. xii. pp. 849, 852.

<sup>3</sup> It does not seem necessary to advert more in detail to the divisions and subdivisions of logic drawn out in the *Kritik*, pp. 83-98 (Hartenstein's ed., 1866).

these, in so far as they make up a concept."<sup>1</sup> But the essential element in the definition—the unity of consciousness or unification of differences in a notion—is thus left so vague and undetermined that it is impossible to deduce from it any classification or any peculiarities of judgments, and possible indeed to proceed on two quite distinct lines of research. The expression, indeed, refers to that which is the fundamental fact in the critical system, the existence of conditions under which only it is possible for detached data of experience to become objects of knowledge for the single conscious subject; and, had Kant been true to the principles of his system, it would then have been necessary to base any classification and treatment of judgment on the enumeration of the functions of unity in conscious experience. In the *Kritik*<sup>2</sup> emphasis is laid upon the function of unity as the essence of the judgment, but it is a well-known historic fact that Kant makes no attempt to justify in its details the enumeration of such functions on which his divisions rest. His followers in the field of logic,<sup>3</sup> misconceiving the real relation of form to matter, interpreted the unity involved in the judgment as being a merely quantitative relation between given notions.<sup>4</sup> There is here involved a twofold error, which has exercised a most pernicious influence on the fortunes of logical theory. For, in the first place, so to view judgment is implicitly to proceed from the assumption of notions as given elements of knowledge, the relations of which are to be discovered by comparison or analysis of what is contained in them. The notion as empirically given thus becomes the fundamental fact; all other forms of thought, judgment, and syllogism are regarded as merely the mechanism by which the content of notions is evolved. Such a doctrine puts out of sight the peculiarities of the notion as the product of thought only, inevitably compels a distinction between what we may call the real processes of thinking whereby notions are formed and the elaborative processes by which notions when formed may be treated, and, by regarding notions as simplest data, leads back to the old nominalist doctrine according to which all thinking is but the compounding and separating of simple elements.<sup>5</sup> And, in the second place, there is involved in all this the underlying prejudice, which it was the very business of the critical system to destroy, the attempt to treat knowledge, and thought, which is an integral part of knowledge, in a purely mechanical fashion. The Kantian analysis for the first time in the history of philosophy brought into clear light the essential peculiarity of knowledge, the reference of all the manifold details of experience to the unity of the thinking subject. Such reference, and the modes in which it expresses itself, are not to be conceived mechanically, nor can we regard the products of thought, the notion, judgment, and reasoning, in the same fashion in which, with but partial success, we treat, in psychology, the representations or reproductions in idea of actual fact. The essence of thought, the unity in difference of objects known and subject cognizing, is that which constitutes in its several modes the peculiarity of notions, judgments, and reasonings. The notion is simply the work of thought, looked at, if the expression be allowed, statically. There is no single psychical product, to be treated by the method of observation which is applied in psychology to sensations and ideas, which can be called the notion. Mental facts, which rightly or wrongly psychology deals with after its mechanical fashion, present themselves in a new aspect when they are regarded as parts, or rather as organic elements, in cognition. If we endeavour to apply the abstracting, isolating method of observation *ab extra* to them, doubtless only mechanical, abstract, and external relations will manifest themselves as obtaining among them, and there may thus be deduced a mass of abstract formulae expressing relations of agreement and disagreement, total or partial coincidence, confliction, intersection, or coexistence and sequence, which have abstract truth, but are in no way adequate to express the genuine nature of thought.

Kant himself proceeds, as was said, by simply assuming, as somehow given, the cardinal forms of unity in consciousness, and, distinguishing form of judgment from matter by the apparently simple difference between matters united and form of uniting, draws out the types of judgment under the familiar rubrics of quality, quantity,

relation, and modality. The same assumption of unity to be given by the higher researches of transcendental logic is manifested in his treatment of reasoning, the deduction of one judgment from others. Three main types of such deduction are signalized:—(1) deductions of the understanding, in which the conclusion follows simply from change in the form of the given judgment; (2) deductions of reason, in which the necessity of the deduced proposition is shown by reference to a general rule under which it falls; (3) deductions of judgment, in which the conclusion is reached by the treatment of given experience in reference to a general rule of reflexion upon experience. Under the first of these fall the familiar forms of immediate inference; under the second, syllogism in its three varieties, categorical, hypothetical, and disjunctive; under the third, inductive and analogical reasoning. The understanding, if one may interpret Kant freely, is the process by which the worth of what is given is fixed and determined; it moves not beyond the given fact, and can therefore subject the fact to no other than formal transformation. The determining judgment or reason is the expression of the fundamental fact in knowledge that all experience is subject to general rules or conditions; there must therefore be a determination of the particular by the general; there must be ground for subsuming the particular and the universal. The forms of such subsumption and determination of the particular by the general are syllogisms. Syllogism therefore is the mode in which the essence of cognition is made explicit. The reflective judgment is the expression of the tendency to treat the contingent details of this or that given experience after the analogy of the general rule that all experience is subject to intellectual determinations. This analogy does not necessitate the specific determination of the particular by any specific universal, but serves as general directrix in experiential researches. It is sufficiently evident that a remodelling of the older logical doctrine such as this rests upon a wider and more comprehensive philosophical view of knowledge as a whole, that such distinctions cannot flow from either of the principles previously indicated as those on which the formal conception of logic rested, and, finally, that the logical aspect of these distinctions is formal in the only true sense of that word, viz., in that the treatment is of necessity general, applicable to all or any thinking.

28. As in the Kantian system there were placed, side by side, two diverse conceptions of logical system, that of transcendental logic, and that of formal logic, without any adequate link of connexion between them, so from the Kantian position there diverged two quite distinct schools of logic, the transcendental or metaphysical, and the formal.<sup>6</sup> As regards the second of these, but little requires to be said. The great body of logical treatises written from the Kantian formal point of view contain nothing of interest. In them the traditional logic is handled under the rubrics supplied by the Kantian general philosophy, with more or less of purification from needless detail, according to the acuteness or insight of the writers, with more or less of deviation from the Kantian lines. In but few cases did the real difficulty, that of assigning to formal logic an independent plan and method, lead to a radically fresh treatment.<sup>6</sup>

The Kantian transcendental logic, being an analysis of the conditions under which objectivity in general becomes possible material for cognition, is in a special sense a new theory of thought. For thought is the process mediating the unity of the ego and the multifarious detail of actual experience; and only through thought, the universal, are objects so determined that they are possible matters of knowledge for a conscious subject. As determinations of objects, the pure elements of thought may be called notions, while the realization of notions in conscious experience is the judgment, wherein the universal of thought and the particular of sense are synthetically united, and the systematization of experience is the syllogism. Notion, judgment, and syllogism are thus, in the transcendental logic, no bare, abstract forms, but have as their content the pure determinations of objectivity in general. They cannot be conceived mechanically, as mere products differing only in degree of generality and abstractness from the ideas, and connexions of association which appear as due merely to the psychological mechanism of the human consciousness. They are the essential forms of the ultimate synthesis through which knowledge becomes possible, and thus express in their organic system the very nature of thought, i.e., of the thinking subject. In the Kantian doctrine, however, as it developed itself historically, there are various points of view which disturb the harmony of the system as thus sketched. Two in particular require special notice, as from these the later attempts at a complete revision of logical theory have taken their origin. (1)

<sup>1</sup> *Logic* § 17.

<sup>2</sup> *Analitik*, § 19.

<sup>3</sup> See especially the treatment of Judgment by Esser (*Logik*, §§ 56 and 61), and Jakob (*Log. u. Met.* §§ 189, 194, 201, 202), where the division of judgments into categorical, hypothetical, and disjunctive flows from a quite arbitrary and artificial principle.

<sup>4</sup> See Twiss, *Logic*, §§ 51–57, and 61; Hamilton, *Logic*, l. 230 sq. It may here be remarked that Hamilton's mode of translating the relative sections of Krug and Esser, his main authorities for the *4*-tails of the Kantian logic, clearly shows that he did not attach any special significance to the phrase, unity of consciousness. In his view, the unity implied in the judgment A is B was the union of A and B in the notion of a given totality or whole—A being part of B in one aspect, B being part of A in another. This relation of whole and part is quite un-Kantian.

<sup>5</sup> It is by this course that the curious phenomenon of an algebraic or symbolic logic springing from the Kantian groundwork has come about. The same result follows, indeed, from any view of thought as merely exercised about facts which are already in themselves completed cognitions. Whether we call these notions (with Hamilton) or *aporia* (with Antisthenes) or elementary data (with Leibnitz) or *simples apprehensives* (with the nominalists), the result is the same.

<sup>6</sup> Generally, the formal logician is compelled simply to take the processes of thought as determined in psychology or metaphysics or what not, and to consider certain aspects of them. His science has, therefore, no independent place, and no method of development. Independence may be striven after, either by attempting to develop all processes of thought and their logical peculiarities from an initial definition of thought solely, or by combining with this definition the view that non-contradictoriness is the one logical quality, and thus assigning to logic the discussion of the conditions of non-contradiction in thought. Of the first, Hamilton may be taken as the type; of the second, Twiss, Esser, and Esser.

Throughout the Kantian work there appears a constant tendency to regard the ego, or central unity of self-consciousness, as merely abstract, as related mechanically, not organically, to the complex of experience in which its inner nature is unfolded. This tendency finds expression in various ways. Thus the synthesis, which has been shown to be the essential feature of cognition, is regarded as on its subjective side a union of intellectual function and receptivity of sense, and the contributions from either side are viewed as somehow complete in themselves.<sup>1</sup> Knowledge, in accordance with this, might be considered to be the mechanical result of the combination or coherence of the two, a combination which in the last resort must appear to the conscious subject as contingent or accidental. (2) Knowledge, the systematic union of universal and particular in experience, is thought as containing in some obscure fashion a reference to the most real world, the realm of things in themselves, and therefore as being, in antithesis thereto, strictly subjective. The processes of thought, by which unity is given to experience, thus manifest themselves as limited in scope, and as being the very ground or reason of the restriction of knowledge to phenomenal in opposition to noumenal reality.<sup>2</sup>

The presence of these two difficulties or perplexities in the Kantian system, which are, indeed, at bottom but one, led to revision of transcendental logic in two directions. The one line proceeded from the analysis of knowledge as the product of intellectual function and receptivity, and, uniting therewith metaphysical conceptions of varied kinds, culminated in a doctrine of cognition which, retaining the distinction between real and ideal as ultimate, endeavoured to show that the forms of the ideal, i.e., of thought, and the forms of reality were parallel. Logic, under this new conception, appeared as a comprehensive theory of knowledge, the systematic treatment of the modes in which thought, conditioned by its own nature and by the nature of the reality upon which it is exercised, develops into knowledge, i.e., of the modes in which a representation of things characterized by universality and evidential force is obtained. On the whole this is the position assigned to logic by Schleiermacher, whose view is followed in essentials, though with many variations in detail, by a large and important school of logical writers.<sup>3</sup>

The second direction may be characterized generally as the attempt to develop fully what is involved in Kant's conception of thought as the essential factor of cognition. Any opposition between metaphysics as dealing with the real and logic as dealing with the ideal element in knowledge appears, in this view, as a mere effort of false abstraction. The very nature of reality is its nature in and for thought. The system of pure determinations of objectivity, which Kant had imperfectly sketched, is not to be regarded as a piece of subjective machinery, because it expresses the inmost conditions of intelligence as such. Nothing is more real than the ego, than intelligence or thought. Transcendental logic, or logic which is at the same time metaphysic, is the only discipline to which the title logic by right belongs. For it contains the complete system of the forms in and through which intelligence is realized. The notion, judgment, and syllogism are doubtless forms of thought, but they have their definite content. They are the modes in which the forms of objectivity are realized for intelligence, and are thus at once abstract and concrete. The so-called formal logic is a mere *caput mortuum*, a descriptive study of some few types of the application of thought to matters of experience. On the whole this is the view of logic developed through Fichte (and in part Schelling) by Hegel, and the Hegelian system shall here be regarded as its complete and only representative.

#### Logic as Theory of Knowledge.

29. The position assigned to logic as theory of knowledge and the range of problems included in it are determined by the general philosophic view of the distinction between the reality to be apprehended by thought and the subjective nature of thought itself. There may be, therefore, numberless variations in the mode of treating logic with general adherence to the one point of view.<sup>4</sup> In the *Dialektik* of Schleiermacher, for example, the fundamental characteristic is the attempt to unite some portions of the Kantian analysis of cognition with Spinozistic metaphysic. Knowledge is regarded as the complex combination of intellect, the formative, unifying, idealizing faculty, and organization or receptivity of sense. The reality or common validity of cognition rests on the uniform nature of organization and on the identity of all ideas in the one

ideal system. The objective worth of cognition is referred on the one hand to the determined connexion between the real universe and the organization through which the individual is part of the real order of things, on the other hand to the ultimate metaphysical parallelism between the system of ideas and reality. The primary forms of knowledge, notion, and judgment, distinct from one another only as being knowledge viewed now as stable now as in process, correspond to the ultimate elements of the real, the permanent force or substance and its variable manifestations. Syllogism and induction, with the subordinate processes of definition and division, analysis and synthesis, are technical modes of the development of notions and judgments, modes by which inchoate notions are rendered definite, by which incomplete judgments are rendered complete.<sup>5</sup>

That there is much valuable and suggestive material in this mode of regarding logic is undoubted, and in the discussion of isolated forms of knowledge, such as judgment, it is always desirable that there should be kept in mind the reference to the ultimate character of objectivity. But the whole point of view seems imperfect and open to such objections as will always present themselves when a principle is not carried out to its full extent. It may, for propædæutic purposes, be desirable to separate the handling of logical forms from metaphysic, but such separation cannot be ultimate. The system of forms of reality to which the forms of knowledge are assumed to correspond must in some way enter into knowledge, and they cannot enter in as an absolutely foreign ingredient, to which knowledge has simply to conform itself. For, if so, these metaphysical categories would be discoverable only by an analysis of concrete knowledge, and they would remain as inferences from the nature of cognition, not as data directly known. The cardinal difficulty which appears in all treatments of logic from this point of view is that of explaining how there comes to be known an objective system of things with characteristic forms or aspects, and it is not hard to see that the acceptance of a reality so formed is but a relic of the pernicious abstraction which gave rise to the Kantian severance of knowledge from noumenal reality.<sup>6</sup> In short the position taken by Schleiermacher and his school, as final standing ground, is but an intermediate stage in the development of that which lay implicit in the critical philosophy.

Moreover, it is hardly possible to assume this point of view without tending to fall back into that mechanical view of knowledge from which Kant had endeavoured to free philosophy. If there be assumed the severance between real and ideal, it is hardly possible to avoid deduction of all that is characteristic of the ideal order from the observed or conjectured psychological peculiarities of inner experience. The real appears only as ultimate point of reference, but in no other way determines the form of knowledge. The characteristic relations which give content to notions, judgments, and syllogisms are deduced psychologically.<sup>7</sup> In the long run, it would no doubt be found that the real key to the position is the belief, more or less expressed, that the systematic view of thought as comprehending and evolving the forms of reality is an unattainable ideal,—that metaphysic, to put it briefly, is impossible. To some extent this is the position taken by Lotze, whose cautious and ever thoughtful expositions are invariably directed to the elucidation of the real *nodi*, the real roots of perplexity or incompleteness of doctrine. In his view logical forms are the modes in which thought works up the material, supplied in inner experience by the psychological mechanism of the soul, in conformity to the ultimate presuppositions with the aid of which alone can harmony, or ethical and æsthetic completeness, be gained for our conceptions of things. But with this doctrine, which approaches more clearly than any other of the type to the metaphysical logic, there is coupled the reserve that any actual point of view from which the development of these presuppositions, their rational explanation, might become possible is unattainable. Our confidence in them is finally of an ethical character, and depends upon our conviction of the ethical end or purpose of all the surroundings within which human life and

<sup>1</sup> Perhaps the most complete treatment of logic from this point of view is that of George, *Logik als Wissenschaftslehre*, 1868. Ueberweg, dissenting from Schleiermacher's view of syllogism and the systematic process of reasoning, lays out more fully what in his view are the aspects of reality corresponding to the typical forms of knowledge. Trendelenburg endeavours to fill up the gap between real and ideal by emphasizing the community of character between motion, as the ultimate reality, and constructiveness in knowledge, the central activity of the ideal.

<sup>2</sup> Thus we find in Schleiermacher (*Dial.* § 132-34) that the ultimate difference of ideal and real is accepted as simple datum. In Ueberweg (*Logik*, § 4 and *passim*) there is continuous reference to an inner order of things, the forms of which are the metaphysical categories, but the actual treatment is altogether independent of these forms, and we may conjecture that, in the last resort, Ueberweg would have explained the characteristics of logical thinking by reference rather to the psychological mechanism than to a supposed nature of things (see *Logik*, §§ 40-42), and thus approximated to the position of Beneke rather than to that of Schleiermacher.

<sup>3</sup> This tendency, which appears in Schleiermacher and Ueberweg, and indeed in all the logics of that school (George's *Logik*, e.g., is hardly to be distinguished from psychology), is prominent in Beneke. It is curious to note a precisely similar result in the logical theory of Mr H. Spencer. Mr Spencer supposes himself to be throughout referring to the nature of reality, but in fact all that is specific in the forms of reasoning developed by him is of psychological origin (see *Pr. of Psych.* v. 38 302-9).

<sup>1</sup> See vol. xiii. pp. 851, 852.

<sup>2</sup> It is unnecessary to consider what exactly was Kant's teaching on either of these points, or what the significance of the relative doctrine may be in his system. It is sufficient for the historical purpose in hand, to indicate the apparent tendency of his work, for from this the later developments take their rise.

<sup>3</sup> See, for an enumeration of the more prominent members, Ueberweg's *Logik*, § 24, a work which itself is an admirable exposition from the same point of view.

<sup>4</sup> It appears an historic error to identify the point of view here referred to with the Aristotelian. The notion of a parallelism between the forms of reality and the forms of knowledge is too definite to be covered by the mere expression, whether in Aristotle or in Plato, of the doctrine that knowledge is knowledge of being.

character is manifested. In logic as in metaphysics we must content ourselves with more or less fragmentary treatment.<sup>1</sup>

### *Logic as Metaphysical.*

33. To understand the peculiarities of this, the final conception of logic, we must take into account the ultimate view of knowledge as that in which thought and reality are united, and of philosophy generally as the attempt to develop the whole system of these abstract determinations of thought by which coherence and intelligibility are given to knowledge. In it there is carried out to the full extent Kant's idea of thought as the ultimate germ of intelligibility.

In the critical system, as we have seen, the fundamental idea was continuously disturbed by the infusion of doctrines which possessed significance only when the problems were treated from a quite opposed point of view. Thus the abstract separation of conscious experience, regulated according to the conditions of the unity of thought, from a supposed realm of reality involved the consideration of the subject as one portion or item of a mechanical whole. In other words, the Kantian system proved itself unable to unite in a comprehensive fashion the two ideas of thought as the universal in experience and of thought as the activity or mode of realization of the individual subject. The central point of view, that which refers all in experience to the unity of thought, was continuously departed from, and as a natural consequence the various forms or modes of thought were treated, not in relation to their ultimate unity, but as isolated facts, to be dealt with by principles resting on a totally opposed doctrine. It is the essence of the Hegelian method to keep continuously in view the concrete unity and totality of thought, to treat each special aspect or determination as an integral portion of an organic whole, a portion which must prove itself unintelligible and contradictory if regarded apart from its relations to the whole, and so to avoid these mechanical separations and abstractions which had proved fatal to the Kantian doctrine. In the development of a method which rests upon and endeavours to retain so comprehensive a point of view, there must of necessity be much that is tentative and imperfect. Differences of opinion regarding the main stages in the development, regarding the particular content of any one stage, are quite compatible with adhesion to the general principle of the whole.<sup>2</sup> But from this point of view only can justice be done to those forms of thought which have always been regarded as the special material of logical treatment: from any other, the treatment must be partial, fragmentary, and, so to speak, external. Thus, notion, judgment, and syllogism are not, in this view, treated as merely subjective modes in which the individual consciousness approaches and works up the material of experience, but as higher, more developed, and therefore richer forms of the determinations of thought in and through which intelligibility of experience is acquired. The whole system of these determinations of thought, the categories, is the matter of logic; the realization of them in subjective experience, or the treatment of the successive phases of consciousness in which abstract thought comes to be recognized in and by the individual, is the matter of the philosophy of spirit, of which psychology is one portion. Doubtless the logical treatment may be led up to by tracing the modes in which the full consciousness of the determinations of thought as the essence of reality is attained, but such introduction is propædæutic merely, and within the logical system itself the starting-point must be the simplest, least definite of those categories whereby for spirit the realm of fact becomes intelligible.

The nature of the opposition between this view and that of the ordinary logic, which in the main rests upon the principle of individualist psychology, that the content of knowledge is derived *ab extra*, from an entirely foreign world of fact, will become more clear if there be considered specially the treatment which under the two methods is given to the notion. Notions, in ordinary logic, are regarded as products formed from the data supplied by presentative and representative experience, and the mode of formation as generally conceived is a continuous process of critical comparison, recognition of differences, similarities, and grouping of like facts. Not only then does the notion present itself as relatively poor and meagre in content, a kind of attenuated individual, not only are the only characteristics presented to the operation of thought mechanical and external, but the final product appears as a mere subjective abbreviation of what is given in experience. In the process, however, even as it is ordinarily conceived, there is more involved than is apparent on the surface. The individuals subjected to the abstracting and generalizing activity of thought are *qualified* individuals, i.e., individuals viewed as determined in their own nature and in respect of thought by a whole network of relations, which when stated abstractly are really of the nature of categories. They are individuals only for a unifying intelligence

which views them under diverse aspects, and these aspects are the blank forms of intelligibility, which it is the very function of logic to consider in system. Moreover, the purely formal acceptance of the notion as a mere mental hieroglyphic or sign stands in sharp contradiction to the view which as a rule accompanies it, and which, for the most part, receives explicit statement in a so-called applied logic or doctrine of method, that in the notion is contained the representation of the essence or truth of reality. It is impossible to retain with any consistency the merely arithmetical or numerical doctrine of the notion, as containing fewer marks than the individual, of the genus as characterized by a less number of attributes than the species, and so on. Underlying all genuine knowledge, all classification, and therefore all formation of notions, is the tendency towards the subordination of parts to a law which determines them. The generic attributes are not simply the points of agreement, but the determining characteristics, and the notion of a thing is the explicit recognition of its nature as a particular manifestation of a universal law.

Thus even within the limits of the ordinary logic there are problems which force upon it the reconsideration of the view which regards the notion as merely a mechanically formed psychological fact. Knowledge, no doubt, is only realized subjectively, in and through psychological facts, but the treatment of it in its nature as knowledge, and the treatment of its psychological aspect, are *toto genere* distinct. The metaphysical doctrine which keeps consistently in view thought as the essence of knowledge in its own nature has therefore to contemplate the notion in strictest relation to thought, as one mode in which objectivity as such is apprehended, made intelligible, and, in a very special sense, as the mode in which the nature of thought is made explicit. Thus the notion can only appear as uniting and comprehending under a new aspect these intellectual determinations whereby things are related to one another in a cognizable system.

The special characteristic of the Hegelian logic, the methodical principle of development of the determinations of thought, requires for its full elucidation a longer treatment than is compatible with the scope of a general sketch. But it seems necessary to add a word respecting certain difficulties or objections which apply, not specially to the methodical principle of Hegel's logic, but generally to the idea of a logic which is at the same time metaphysics or a treatment of ultimate notions. These objections may be variously put, according to the special point of view assumed by the critic, but they are in the long run dependent on one mode of interpretation of the fundamental antithesis between being, or reality, and thought. For whether we say that it is confusion to identify thought-forms with relations of fact, that it is unphilosophical to assume that being of necessity conforms to thought, that thought is purely subjective and knowledge the system of forms in and through which the subjective is brought after its own nature to an adequate representation of objective fact, or point to phenomena of perception as showing that even adequate correspondence, not to speak of identity, between subjective and objective must be matter of discussion, or lay stress upon the procedure of science as negating the preliminary assumption of the logico-metaphysical assumption, we but express in varied ways a fundamental interpretation of the opposition between reality and knowledge. We assume an initial distinction, the grounds and precise nature of which are never made clear. For the antithesis between thought and reality is an antithesis in and by means of conscious experience, and is not to be comprehended save through conscious experience. If, indeed, we start with conscious experience as a mechanically formed *tertium quid*, something which arises out of the correlation of an unknown subject and an unknown object, we may certainly retain, as an ever-recurring and insoluble problem, the possibility of cognizing either factor *per se*. But the problem arises not from the antithesis but from our way of reading or interpreting it. Opposition between subjective thinking and the real world of fact, slow, tentative, and imperfect development in individual consciousness of knowledge which contains in essential relation the opposed elements, distinction therefore of the metaphysical or real categories which determine the nature of object as knowable from the ideal or logical categories which express more specifically the fashion in which the knowable object is reduced to the subjective form of cognition, are not only perfectly compatible with, but are, strictly reasoned conclusions from, the ultimate doctrine that in thought alone is to be found the secret both of knowing and of being. To bring against this doctrine the continuous complaint that it assumes an identity which, if it can be proved at all, at least demands proof, is to misunderstand the very notion of identity which plays so important a part in the objection. Not even in the most judicious and thoughtful critics of metaphysical logic, in Lotze for example,<sup>3</sup> does one find a sufficiently careful distinction between a mere question of nomenclature (i.e., whether we shall restrict the title *logic* to the portion of general system which deals with notions, judgments, and syllogism, while reserving for metaphysics all the other inquiries) and the question of theoretical

<sup>1</sup> Lotze's whole view of the genetic connexion of the forms of thought is peculiar to himself, and deserves separate treatment.

<sup>2</sup> Hegel himself fully recognizes the tentative character of the numerous divisions and classifications of the categories of thought which make up the substance of the *Logic*, and deems that too much stress be not laid on the formal side of his exposition (see *Logic*, I, 29).

<sup>3</sup> See his *Logic* (1843), pp. 10, 11, and *Logic* (1874), bk. III, chaps. 4, 5.

Importance, whether there remains over and above the difference between the more immediate determinations of thought and its more complex or reflective modes an essential difference in knowledge between thought and reality. In less careful critics the oversight simply leads to the contention that we shall always repeat the problem of knowing and being as insoluble, and shall view knowledge as a mechanical, subjective product.

Many of these objections doubtless result from a very simple fact, more than once alluded to in this article. Particular distinctions, apparently the most elementary, frequently involve and are unintelligible apart from a developed, though not necessarily consistent or well grounded, conception of things in general. Thus the emphasis laid upon thought as essentially subjective, as being merely the system of operations whereby the individual brings into order and coherence in his own experience what is furnished *ab extra* through the natural connexion in which he is placed to the objective world, seems at first sight the most simple and direct consequence of the actually given distinction between the individual as one natural unit and the sum of things comprehending him and all others. But, on analysing more closely the title for applying to philosophical problems a view which is that of practical life, and doubtless legitimate and necessary within that sphere, we readily become aware of a whole series of speculative assumptions implicit in that view, and possibly without any adequate justification. At all events, whether or not the view be ultimately defensible, and in the same form in which it is at first assumed, it is unphilosophical to start in the treatment of a difficult and important discussion from principles so ambiguous and undetermined. The practical difference between the individual agent and the external sphere within which his individual operations are realized and which is therefore treated by him, from his point of view, as external, throws no light *per se* on the nature of the ultimate relation between the individual thinker as such and the world within which his thought is exercised. The confusion between ultimate distinctions and practical points of view is productive of most pernicious consequences not only in logic specially but in philosophy at large.

#### Criticism of the Chief Logical Schools.

31. It will probably be now apparent that determination of the nature, province, and method of logic is, and has always been, dependent on the conception formed as to the nature of knowledge. Discussions regarding the precise definition of logic are not mere analytical disputes regarding the best mode of expressing in terms the nature of a subject sufficiently agreed upon; variations in the treatment of particular portions of logical discipline do not arise from more or less accurate discrimination of the nature and relations of given material; nor are differences in respect to the amount of logical matter to be considered mere expressions of difference as to the range of the same fundamental principles. The grounds for divergence are much more deeply seated, and, looking back upon the historical survey of the main conceptions of logical science, it seems quite impossible to hope that by comparison and selection certain common points of view or methods may be extracted, to which the title of logical might beyond dispute be applied. The logic, as one may call it, of each philosophical theory of knowledge is an integral part or necessary consequence of such theory; and its validity, whether in whole or in part, depends upon the completeness and coherence of the explanation of knowledge in general which forms the essence of that theory. Any criticism of a general conception of logic or special application thereof, which does not rest upon criticism of the theory of knowledge implied in it, must be inept and useless. It is not possible to include such expanded criticism in an article like the present; there remains therefore only one aspect of these various logical schemes which may be subjected to special and isolated examination, viz., the inner coherence of each scheme as presented by its author. Naturally such an examination can be applied only to views which imply the separate existence of logic as a body of doctrine developing into system from its own, peculiar principles. When it is a fundamental position that logic as such has no separate existence, but is one with the all-comprehensive doctrine or theory of the ultimate nature of cognition, it is not possible to criticize such conception of logic separately; criticism of logic then becomes criticism of the whole philosophical system. In most of the views brought before us, however, a special place has been assigned to logic; it is therefore possible to apply internal criticism to the more important of these general views, and to consider how far the pretensions of logic to an independent position and method are substantiated.

From the foregoing remarks it will also have become apparent that a general classification of logical schools, as proposed to the

but from such equally formal logics as those of Hobbes, Condillac, Leibnitz, Herbart, Ulrici, Boole, De Morgan, and Jevons. Lagrange's theory of knowledge presents quite special features when handled by Mill, or by Schleiermacher, Ueberweg, Beneke, and Wundt. And it cannot even be admitted that the threefold classification affords room, without violence, for the Aristotelian logical researches. There are no points of agreement and difference so unambiguous that by their aid a division can be effected.<sup>1</sup>

32. Few conceptions of logic contain, with so little real ground, such professions of completeness and independence as that developed in the writings\* of the Kantian school.<sup>2</sup> According to this view, logic is a pure science, having as its special material the form of thought, demonstrative in character and with theorems capable of complete deduction from the elementary principles contained in the very notion of form as opposed to matter of thought. But, when one comes to the examination of the system itself one finds (a) that the notions of form and matter are much too stubborn to lend themselves readily to analysis, and that explanations of what exactly constitutes form fluctuate between a merely negative definition (whatever is not treated in any other science, philosophical or otherwise) and a psychological deduction from the assumed nature of thought;<sup>3</sup> (b) that the really important factor in determining the contents of logical science is psychology, from which much more is borrowed than the mere preliminary definition of thought; (c) that demonstrative character rests entirely on an abstract interpretation of the laws of identity and non-contradiction;<sup>4</sup> (d) that throughout the whole system there is not a trace of development, but merely the reiterated application of the law of identity and contradiction, or of some confused distinction between form and matter, to logical products, the notion, judgment, and syllogism, whose nature, characteristics, and distribution are arbitrarily accepted from psychology or general criticism or what not. Thus, in the majority of cases, logicians who simply followed the lines indicated by Kant introduced into their system, without any criticism, the fundamental distinctions contained in the *Kritik der reinen Vernunft*. The fourfold scheme of quantity, quality, relation, and modality was applied without hesitation, though in varied and always artificial fashion, to notions;<sup>5</sup> judgments were accepted as being categorical, hypothetical, and disjunctive in kind, though the differences are altogether foreign to the logical principle applied; and generally no attempt was made to do more than treat, in an abstract fashion, some aspects of a procedure of thought determined in all its phases by extra logical considerations. The inevitable result of such a treatment was the undue preponderance given to the doctrine of notions, which, being viewed after the fashion of Kant as given, completed product, appeared as the ultimate units of thought, to be combined, separated, and grouped together in all the higher processes. The peculiarities of the logical system which is commonly associated with the name of Sir W. Hamilton spring entirely from this view of notions. For, if notions be regarded as the elements of thought, then the judgment which elaborates them can only present itself as the explicit statement of immediate relations discernible among notions. These immediate relations reduce themselves, for Hamilton, to one,—the quantitative relation of whole and part, and, attention being concentrated on the extensive reference of concepts, the eightfold scheme of propositional forms is the natural consequence. To such a scheme the objections are manifold. It is neither coherent in itself, nor expressive of the nature of thinking, nor deduced truly from the general principle of the Hamiltonian logic. For it ought to have been kept in mind that extension is but an aspect of the notion, not a separable fact upon which the logical processes of elaboration are to be directed. It is, moreover, sufficiently clear that the relation of whole and part is far from exhausting or even adequately representing the relations in which things become for intelligence matters of cognition, and it is further evident that the procedure by which types of judgment are distinguished according to the total or partial reference to extension contained in them assumes a stage and amount of knowledge which is really the completed result of cognition, not that with which it starts, or by which it proceeds.<sup>6</sup>

The utility of basing logical theorems on psychological premises, a method involved in the procedure of most expositions of formal

<sup>1</sup> Nor are more detailed classifications, such as those of Rosenkranz (*Die Metaphysik der Logik*, 1842), Præd (*Die Bedeutung der Logik*, 1849), Balzer (*Lehrb. d. Philosophie*, 1880), of service, except when historical.

<sup>2</sup> Under this head Kant himself, for reasons above given, is not included; the writers referred to are named in Ueberweg (*Logik*, § 24).

<sup>3</sup> Mill's criticism on Hamilton's confused statements regarding forms (*Exam. of Hamilton*, 138-153), is perfectly applicable to the generality of the Kantian treatises on logic.

<sup>4</sup> See, e.g., Kne, *Logik*, § 25 sq. v.

<sup>5</sup> The extension of a notion has no numerical or quantitative definiteness. To formulate the judgment as expressing definite amounts of extension, therefore, presupposes complete empirical survey of what, by its very essence, remains incomplete. This is specially noteworthy in the case of Hamilton's particular

knowledge of the whole spheres of A and B. It is in the strictest sense of the word *universal*. Hamilton, it may be added, finds it completely impossible to work out a coherent doctrine of syllogism from the point of view taken in the treatment of the judgment.

but, of, as certain external conditions, especially the *external* (theoretisch), and metaphysical conceptions of logic is rather confusing than helpful. For the formal logics of the Kantian writers, of Hamilton, and of Mansel are distinct, not only from one another,

logic, may well be matter of doubt. For psychology, as ordinarily conceived, has certainly close relations with logic, but in aim and in point of view is distinctly opposed or at all events subordinate to it. The psychological investigation of thought, if carried out consistently, must take one of two forms, either that of description, in which thought, like any other mental fact, is regarded *ab extra* as that upon which attention and observation are to be directed,—in which case therefore any relations of thoughts among themselves must be of such an external nature as can be presented in the field of observation; or that of genesis, development, in which the subjective processes of mind are viewed as forms of the one great process whereby knowledge is realized in the individual consciousness. Investigations from the first point of view are diametrically opposed to the logical treatment of thought, for in the latter the essential feature, the reference in the subject, with his mental forms, to an objective order within his experience is entirely wanting. Such investigation is abstract; it proceeds upon and remains within the limits of a distinction drawn in and for conscious experience, a distinction the grounds, significance, and modes of which require to be treated by a larger and more comprehensive method. Investigations from the second point of view are subordinate to logic in the wider sense, for the treatment of the subjective processes therein is illuminated and determined by the general principles regarding the nature and meaning of conscious experience which it is the sole function of logic to bring forward and establish. The psychology which Hamilton generally has in view is that commonly called empirical, and with his conception of it the two sciences, logic and psychology, are really one.

33. A possible exit from the difficulties or assumptions of the current Kantian logic may be sought by following out and consistently applying the hint contained in Kant's distinction of analytic and synthetic thought, analytic and synthetic truth. It may be said that all thinking involves the fundamental laws of identity and non-contradiction; that in these laws only is to be found the characteristic and most general feature of thought; that in them only is the form, or element contributed by mind itself, to be detected. Logic would thus be regarded as the explicit statement of the conditions of non-contradictoriness in thought, as the evolution of the formal element in thought, and, since in analytic truth only can non-contradictoriness be discovered without material aid, as the theory of analytic thought. Such is the position assigned to logic by Twisten, Mansel, Spalding, and some others, and the consequences to which it inevitably leads are sufficiently interesting to require that some special examination should be given to it.

In the first place, then, it seems evident that the fundamental distinction implied, that between analytic and synthetic thought, is wrongly conceived. That analysis and synthesis are methods of cognition, differing in many important respects, is undoubted; but such difference lies in a sphere altogether alien to that within which the present distinction is to be sought. Analytic thought, as here conceived, is only to be understood when taken in reference to the judgment, and then also in reference to a peculiarity in the Kantian doctrine. Kant, emphasizing the principle that judgment is essentially the form in which the particular of experience is determined by the universal element of thought, but identifying this universal with a formal concept (resembling, therefore, a class notion), contemplated a class of judgments in which the predicate was merely an explication of the subject notion. Such judgments, had the matter been more fully considered, would have appeared as far from primary, and Kant has himself, in the most unambiguous language, indicated the correct view that analysis is consequent and dependent on synthesis,—that analytic judgments, therefore, are merely special applications of abstracting thought within a sphere already treated, handled, formed by thought. Mansel, too, whose views are generally acute if not profound, has signaled as the primitive unit of cognition the so-called psychological judgment, which is essentially synthetic in character. The logical judgment, in fact, about which his conception of logic centres, is recognized as a posterior act of reflexion, directed upon formed notions, and is not in any way to be regarded as containing what is a common, universal feature of all judgments.

In the second place, even granting what cannot be maintained, that the process of thought is mere explication of the content of previous knowledge, and that the theory of logic has to do with a comparatively small and subordinate portion of cognition, there is in such a principle no means of development. We may take up in succession class-notions, judgments, reasonings, and in relation to each reiterate, as the one axiom of logic, that the constituent elements shall be non-contradictory; but such a treatment is only possible in relation to a material already formed and organized. Its utmost possible value being given to such a view, logic, under it, could be but a partial and inchoate doctrine.

Finally, there is involved in the doctrine of analytic thought, and in the consequences to which attention will next be drawn, a peculiar and one-sided conception of identity or of the principle of identity as an element in thought. Historically this conception has played a most important part: it lies at the root of all nominalist logic from Antisthenes downwards, and has found metaphysical expression of the most diverse kinds. *That things are what they are* is the odd fashion in which a well-nigh forgotten English writer states what is taken to be the universal foundation of all thought and knowledge.<sup>1</sup> The representatives of things in our subjective experience, the units of knowledge, may be called notions, and, accordingly, that each notion should be what it is appears as the corresponding logical axiom. The whole process of thought is therefore regarded as merely the explicit statement of what each notion is, and the separation of it by direct or indirect methods from all that it is not. The judgment, essentially the active movement of thought, is reduced to the mere expression of the identity of a notion, and in truth, were the doctrine consistently carried out, Antisthenes's conclusion that the judgment is a fallacious and inept form of thought would be the necessary result. When such a conclusion is not drawn, its place is generally taken by much vague declamation regarding the limited, imperfect, and uncertain character of our knowledge, which is regarded as asymptotically approaching to the adequate determination of truth.

The conception which underlies this view is the abstract separation of thought from things which has been already noted, but the proximate principle is a deduction therefrom. Knowledge or thought is treated externally as a series of isolated units or parts, and the results of cognition—*notions, judgments, and reasonings*—are viewed as the constituent factors. Thus, *e.g.*, when it is said that a judgment is the expression of an identity, there are possible only two modes of explanation,—the one, that the identity referred to is that between the original notion (subject) as unqualified by its predicates and the same as qualified, in which case manifestly the result of the judgment is taken as being its constituent essence; the other, that the identity is that of the applicability of distinct names to the same fact, in which case we accept without further inquiry and exclude from logical consideration the processes of thought by which the application of names is brought about, and assume as being the procedure of thought itself that which is its consequence. Under all circumstances, difference is as important an element as identity in the judgment, and to concentrate attention upon the identity is to take a one-sided and imperfect view.<sup>2</sup>

34. So soon, however, as the real nature of thought has been thrown out of account as not concerned in the processes of logic, so soon as the law of non-contradiction, in its manifold statement, has been formulated as the one principle of logical or formal thinking, there appears the possibility of evolving an exact system of the conditions of non-contradictoriness. The ultimate units of knowledge, whatsoever we call them, whether notions or ideas of classes or names, have at least one characteristic,—they are what they are, and therefore exclude from themselves whatever is contradictory of their nature. They are combined positions and negations, that which is posited or negated being left undetermined,—referred, in fact, to matter as opposed to form. With respect to any article of thought, therefore, the only logical requirement is that it shall possess the characteristic of not being self-contradictory, and the only logical question is, what exactly is posited and negated thereby. Complex articles of thought viewed in like manner as complexes of positions and negations may have the same condition demanded of them and the same question put regarding them. A judgment and a syllogism, if narrowly investigated, will appear to be merely complex articles of thought, complexes of positions and negations. Proceeding from such a conception there may be treatments more or less systematic and fruitful. In the hands of Kantian logicians, such as Twisten, Mansel, Spalding, and the like, little is effected, for, as the forms of thought are accepted as given and as having their characteristics otherwise fixed (by psychology or critical theory of knowledge), the treatment resolves itself either into repetition, in respect to each, of the fundamental logical condition, or into the erection of a specific kind of thought (analytical) which has no other feature save that of correspondence with the said condition. But it is clear that restriction by any psychological or critical doctrine of thought is an arbitrary limitation. It is needful only to regard the operation of thought as establishment of positions and negations, and to develop, by whatever method, the systematic results of such a view. Hobbes's doctrine of thought as dealing with names and as essentially addition and subtraction of nameable features, Boole's doctrine of thought as the determination of a class, Jevons's view of thought as simple apprehension of qualities,—any of these will serve as starting point, for in all of them the fruitful element is the same. The further step that the generalization of the system of thought must take a symbolic form presents itself as an immediate and natural consequence.

35. By the application of a symbolic method it is not to be understood what has been practised by many writers on logic—the illu-

<sup>1</sup> John Sergeant. See *The Method to Science*, by J. S., 8vo, Lond., 1696, pp. 144, 146. This curious book contains much interesting matter.

<sup>2</sup> On Comillac's attempt to treat judgments as identities (or equations) some excellent remarks will be found in De Tracy, *Idéologie*, III. 133-143; cf. Duhamel, *Des Méthodes*, I. 80-84.

tration of elementary logical relations by numerical or algebraic signs or by diagrammatic schemata. The expression has the significance which it bears in mathematical analysis, and implies that the general relations of dependence among objects of thought, of whatsoever kind, in correspondence with which operations of perfectly general character are carried out, shall be represented by symbols, the laws of which are determined by the nature of these relations or by the laws of the corresponding operations. The mere use of abbreviations for the objects of treatment is not the application of a symbolic method<sup>1</sup>; but so soon as the general relations of, or general operations with, these objects are represented by symbols, and the laws of such symbols stated as deductions therefrom, there arises the possibility of a symbolic development or method of treatment, which may lead to more or less expanded results according as the significance of the symbolic laws is more or less general. Thus quantity, whether discrete or continuous, presents, as an aspect of phenomena, relations of a highly general kind, offers itself as object of operations of a highly general kind, and is therefore peculiarly the subject of symbolic treatment. Currently, indeed, the treatment of quantity is assumed to have the monopoly of symbolism, but such an assumption is not self-evidently true, and it is permissible to inquire whether matters non-quantitative do not present relations of such generality that they, too, can be symbolically dealt with. It is, however, a further question whether the generality of the relations and therefore the significance of the symbols in such cases, although subject to some special conditions not necessarily involved in the nature of quantity, do not spring from the fact that we treat the matters as quantities of a special kind, and so insensibly find ourselves applying quantitative methods. In other words, it remains to be investigated, after the preliminary definitions and axioms of any symbolic method have been laid down, whether the conception of thought with which we start, or a special feature distinctly quantitative in character, has been the truly fruitful element in after-development of the system.<sup>2</sup>

The first step in any symbolic logic must evidently be the determination of the nature and laws of the symbols, and, as these follow from the nature of the operations of thought, the first step is likewise a statement of the essential characteristic of thinking. As above noted, there have been adopted various modes of expressing this characteristic, and in some cases the mode adopted is not one from which any generally applicable symbolic rules of procedure could have followed.<sup>3</sup> Two only require here to be noted, as representing special views: first, that which proceeds from the idea of thought as essentially the process of grouping, classing, determining a definite set of objects by a mark or notion; and second, that which proceeds more generally from the conception of thought as consisting of a series of self-identical units, to be variously combined in obedience to the law of self-identity.<sup>4</sup> Adopting the first view, we find that processes capable of symbolic representation, by the customary algebraic signs of addition, subtraction, equivalence, multiplication, and division, have a perfectly general significance in reference to the combination, separation, equalization of classes, to the imposition and removal of restriction on a class; that to the symbols there can therefore be assigned a set of general laws; and that any peculiarity of these symbolic laws which differentiates them from the laws of like symbols in mathematical analysis is deducible from the notion of thought with which we started, and is consequently to be carried along with them in all the after development. Symbolic representation of relations of classes follows with equal directness from the general notion that by any such relation a new group is determined in reference to the original groups, or rather that the position or negation of a new group (or series of groups) is given, definitely or indefinitely, as the result of such a relation.

With the aid of the symbolic laws so reached, the logical problem as such may then be approached. Given any number of logical terms (i.e., classes, or, as it may be better put, positions and negations) connected together by any relations, to determine completely any one in reference to the others, or to express any one in terms of the others. The symbolic procedure, expounded with marvellous ingenuity and success by Boole, may take various forms, and may be simplified by many analytical devices, but consists essentially in determining systematically how given positions and negations,

definite or indefinite, combine with or neutralize one another. A more detailed account of these formal processes is beyond our limits.<sup>5</sup>

The first question which suggests itself in connexion with Boole's symbolic logic is the necessity or advisability of retaining the reference to classes, or the description of thought as classification. Do the symbolic laws really depend to any extent on the logical peculiarities of class arrangement? Mr Venn, who emphasizes this feature in Boole's scheme, has, however, done good service in leading up to a different explanation. The general reference to objects, which is also noted as implied in all Boole's formulæ, has nothing to do with the possible difference of conceptualist or materialist doctrines of the proposition, and, in fact, as all distinctions of thing and quality, resemblance and difference, higher and lower, subject and predicate vanish, or are absorbed in the more general principle underlying the symbolic method, phrases such as classification, extension, intension, and the like should be banished as not pertinent. Nay, the usual distinctions of quantity and even of quality either disappear or acquire a new significance when they are brought under the scope of the new principle. "What symbolic logic works upon by preference is a system of dichotomy, of  $x$  and not  $x$ ,  $y$  and not  $y$ , and so forth."<sup>6</sup> In other words, quantitative differences require to find expression through some combination of the positions and negations of the elements making up the objects dealt with,<sup>7</sup> while the usual qualitative distinctions are merged in the position or negation of various combinations.

The whole phraseology then of classification and its allied processes seems needless when used to denote the simple determination of objects thought. The literal signs express, not "classes," but units, determined in and for thought as self-identical. For this reason then it appears that the view of the foundations of the symbolic methods of logic taken in Grassmann's *Begriffsschere* is more thoroughgoing, and more closely represents the underlying principles, than that involved in Boole's formulæ and expounded in detail by Mr Venn.

Grassmann, as above stated, deduces logical relations as a particular class of the determinations necessarily attaching to all quantities (i.e., determined contents of thought). Abstraction being made of all peculiarities which may be due to their special constitution, quantities exhibit certain formal relations when they are combined (added, subtracted, &c.). Each quantity is a unit of thought, a definite *positum*, and of such units there are but two classes, elements and complexes. Units of thought, which are self-identical, and therefore subject to the specific law that addition of each to itself or multiplication of it by itself yields as result only the original unit, are notions. The theory of notions, therefore, is the development of the general formal relations of units under the special restrictions imposed by their nature.<sup>8</sup>

There appears very clearly in Grassmann's treatment the essence of the principle on which symbolic logic proceeds. Thought is viewed as simply the process of positing and negating definite contents or units, and the operations of logic become methods for rendering explicit that which is in each case posited or negated. To apply symbolic methods, we require units as definite as those of quantitative science, and the only laws we can employ are those which spring from the nature of units as definite. Now it seems a profound error to reduce the whole complex process of thinking to this reiterated position of self-identical units. Undoubtedly if we start from any given fact of thought, as, e.g., a judgment, and inquire what can be exhibited as involved in it, we have before us a problem of analysis, the solution of which must take form in a series of positions and negations, but our thinking is not therefore as a whole mere analysis. The synthetic process by which connexions of thought among the objects of our conscious experience are established is not the mechanical aggregation of elementary parts. The relations which give intelligible significance to our experience are not simply those of identity and non-identity. It is an altogether abstract and external view of thought, resting in all probability on an obscure metaphysical principle,<sup>9</sup> that would treat it as in essence the composition and decomposition of elementary atoms, of *ἁτὰρ*, as Antisthenes would have called them. It has, indeed, been imagined that a symbolic logic might be developed which should be independent in all its fundamental axioms of any metaphysical or psychological assumptions, but this is an illusion. No logical method can be developed save from a most definite conception of the essential nature and *modus operandi* of thinking, and any system of symbolic logic finds it necessary, if it is to be complete and consistent, to adopt some such view as that above criticized, to regard thought as purely analytic, as dealing with compounds or

<sup>1</sup> Thus one would not describe Aristotle's use of letters for the terms of his syllogisms, nor the current logical abbreviations of S, P, and M in like case, as being, in any true sense of the word, symbolic. On the subject generally, the instructive work of Mr Venn (*Symbolic Logic*, 1881) should be consulted. Mr Venn has not only in this work expounded the foundations and main theorems of Boole's logic with a care and skill that leave nothing to be desired, but he has, independently of many real contributions to logical analysis, put in its true light the nature of symbolic method in logic. He has rendered it impossible, even for the optician, to complain that symbolic logic is an arbitrary application of mathematical method to logical material.

<sup>2</sup> An excellent note on symbolic logic will be found in Lotze, *Logik* (2d ed., 1880), pp. 255-60.

<sup>3</sup> Some of these, as, e.g., Lambert's and Plonquaux's, are noted and discussed by Mr Venn (*Symbolic Logic*, xxiii.-xxvii. and *passim*).

<sup>4</sup> The first is the view taken by Boole and is expounded with great fulness in Venn, as above; the second is that of the brothers Grassmann (in the *Formenlehre*, 1879, especially bk. II. *Die Begriffsschere oder Logik*).

<sup>5</sup> Mr Venn's work is here again invaluable. Jevons's *Principles of Science and Studies in Deductive Logic* should be consulted. Schröder's *Op. atomikens des Logikkalküls* contains so very elegant and simple methods.

<sup>6</sup> Venn, as above, p. 162.

<sup>7</sup> Where this is impossible, as in the case of the truly particular or indeterminate judgment, symbolic methods encounter almost insurmountable difficulties.

<sup>8</sup> See *Die Begriffsschere oder Logik* (1872), p. 43. Schröder (*op. cit.*) follows Grassmann, though with the use of class phraseology.

<sup>9</sup> As above noted, p. 800.

units which are themselves highly complex products, only to be formed by a kind of thought not recognized among logical processes.<sup>1</sup>

36. Formal logic, then, in the ordinary acceptance of that term, does not appear to furnish any adequate representation of the real process and method of thought. Any logical theory must of necessity be formal, i.e., abstract or general, for it can consider only the general elements of thought, not specific knowledge in which are involved the finite, limited relations of one fact or class of facts to another. The distinction between logic and the sciences is therefore precisely that between philosophy in general and the sciences. Attempts have been made to include in logical analysis the treatment of scientific method, i.e., to discuss as matter of logic the varied processes by which scientific results have been attained. It is true that logical consideration must extend to the notions through which scientific experience, like any other, becomes intelligible, and, in so far as scientific method is but the application of the laws of knowledge as a whole, it is a possible, nay necessary, object of logical treatment. But to include scientific methodology in particular, the consideration of the mechanical devices by which we strive to bring experience into conformity with our ideal of cognition, the discussion of methods of experiment and observation, under the one head logic is an error in principle, whether we view logic in its theoretical aspect or in reference to a special propædæutic aim. Generalizations on such topics are well-nigh worthless; they can have vitality and importance only when drawn in closest conjunction with actual scientific work. The theory of scientific method is either doctrine of knowledge treated freely or else the application of thought in connexion with actual research and the ascertainment of the principles therein employed. In either case it is not susceptible of abstraction and isolated treatment.

37. There remains only, of the possible views noted, that which identified logic with the theory of knowledge, but which so defined theory of knowledge as to distinguish it from metaphysics. The designation of logic as theory of knowledge is one to which in words there can be no possible objection. It brings into the foreground what it has been the object of this article, by an historico-critical survey, to establish, that so-called logical laws, forms, and problems are hardly capable of statement, certainly incapable of satisfactory treatment, except in the most intimate connexion with the principles of a theory of knowledge. To include, however, in the signification of this latter term a peculiar conception of the relation between thinking (knowing) and reality is at once to restrict the scope of logic and to place an arbitrary and, one would say, an ill-founded restriction on the kind of treatment to which logical problems may be subjected. If it be really the function of logic to trace the forms and laws of knowledge, that function is all-comprehensive, and must embrace in its scope all the fundamental characteristics of experience as known. But no characteristic of experience is more palpable than the distinction, drawn within conscious experience, between knowledge and reality. It is impossible then for a theory of knowledge to start with the assumption that these two exist separately, constituted each after its special fashion, but with a certain parallelism between them. In words one may resort for justification of the assumption to metaphysics, or to psychology, but, in fact, the problem so relegated to some other discipline is essentially a logical question, and the method of its solution exactly that which must be applied in the treatment of subordinate logical questions. Practical convenience alone can lead to any separation of the problems which under this view are referred in part to theory of knowledge and in part to metaphysics. Other and more serious difficulties of the view have been already commented on.<sup>2</sup>

38. In sum, then, the problems and the methods which compose logic in the strictest sense of that term seem to be one with the problems and methods of the critical theory of knowledge. No other title describes so appropriately as that of "logical" the analysis of knowledge as such, its significance and constitution, in opposition to the quasi-historical or genetic account for which the title psychological should be retained. The researches to which we would here assign the title "logical" undoubtedly include all that can supply the place of the older metaphysics, but in aim and method are so distinct that the same title cannot be borne by both. To assign so extensive a range to logical investigations enables us to see that the criteria by which at one time or another a narrower province was determined for logic are but partial expressions of the whole truth. The analysis of knowledge as such, the complete theory of the intelligible elements in conscious experience, does hold a special relation to all other subordinate branches of human thinking, whether philosophic in the ordinary sense of that term or scientific. According as one or other aspect of this relation is made prominent, there comes forward one or other of the various modes for settling the province of logic; but these partial concep-

tions prove their inadequacy when development is attempted from them, and within the systems constructed in accordance with them there is of necessity continuous reference to inquiries lying beyond the prescribed limits.

A certain analysis of some methods of ordinary thinking, based to a very large extent on language, and resembling in many respects grammatical study, has long been current in educational practice as logic, and to those whose conception of the subject has been formed from acquaintance with this imperfect body of rules and formulæ it may appear a violent and unnecessary extension of the term to apply it to the all-comprehensive theory of knowledge. The reasons, however, are imperative; and, as these would lead one to deny the right of this elementary practical discipline to the possession of the title, it is desirable to conclude by offering a single remark on the place and function of this currently designated logic.

Not much trouble is required in order to see that the ordinary school or formal logic can lay no claim to scientific completeness. Its principles are imperfect, dubious, and most variously conceived; it possesses no method by which development from these principles is possible; it has no criterion by which to test the adequacy of its abstract forms as representations of the laws of concrete thinking. Accordingly it is handled, in whole and in detail, in the most distractingly various fashion, and were it indeed entitled to the honourable designation of logic the prospects of that science might well be despaired of. But in fact the school logic discharges a function for which exhaustiveness of logical analysis is not a requisite. It has a *raison d'être* in the circumstance that training to abstract methods must needs be a graduated process, and that, whether as a means towards the prosecution of philosophic study in especial, or as instrument of general educational value, practice in dealing with abstract thoughts must have value. Such elementary practice naturally bases itself on the kinds of distinction apparent in the concrete thinking of those to whom it is applied, and for this reason school logic not only connects itself with and is in a sense the development of grammar and grammatical analysis and synthesis, but may, to a limited extent, include reference to some of the simpler processes of scientific method. In all probability the discord observable among the ordinary treatises on school logic is due to the want of recognition of the true place which can thus be assigned to the subject treated. The doctrine has a propædæutic but not a scientific value.

#### NOTE A.

*Histories of Logic.*—No complete history of logic, apart from philosophy in general, exists; but of the Aristotelian logic, in its system and in its development throughout the ancient and mediæval epochs we possess a most adequate history in Prantl's *Geschichte der Logik im Abendlande* (I, 1855; II, 1861; III, 1867; IV, 1870), extending to the close of the mediæval period.

The following are some of the more important contributions towards a history of logic, whether in independent works or in portions of systematic treatises; most of them, indeed, of small value:—Ramus, *Scholæ Dialecticæ*, bk. I. chap. 1 & 2; Keckermann, *Systema Logice*, 1686; Gassendi, *Opera*, I. 35-66; Fabricius, *Specimen elenchicum historie logicæ*, 1690; Walch, *Panopæa Academica* (1721), pp. 453-848; Darjes, *Via ad Veritatem*, appendix, 1755; Buhle, in *Comment. Soc. Gotting.*, vol. x.; Fülleborn, *Beiträge z. Gesch. d. Phil.* (1799), pt. iv. pp. 160-80; Eberstein, *Gesch. d. Logik u. Metaphysik bei den Deutschen von Leibnitz bis auf gegenwärtige Zeit* (2d ed., 1791), useful as a survey of the whole; Calkers, *Denktheorie* (1822), pp. 12-198; Bachmann, *System der Logik* (1828), pp. 569-614; Musmann, *De Logice ac Dialectice notionibus historicis*, 1828; Tröxler, *Logik* (1830), vol. III.; Sigwart, *De historia logicae inter Græcos usque ad Socratem*, 1832; St. Hilaire, *De la Logique d'Aristote* (1838), n. pp. 93-312; Franck, *Esquisse d'une histoire de la logique*, 1838; Reiffenberg, *Principes de logique*, 1839 (with bibliography); Trendelenburg, *Gesch. d. Kategorienlehre*, 1846; Blakey, *History of Logic, and Essay on Logic* (2d ed., 1848), with bibliographical appendix; Hoffmann, *Grundzüge einer Geschichte der Logik in Deutschland von Kant bis Baader*, 1851; K. Fischer, *Logik u. Metaphysik* (2d ed., 1860), pp. 16-182, a valuable critique of some modern doctrines; Rabus, *Logik und Metaphysik* (1868), I. pp. 223-212, excellent; Ueberweg, *System der Logik* (4th ed., 1843), pp. 15-66, excellent critical account; Rugmose, *Storia critica delle Logiche*, 1871, 2 vols.; Rabus, *Die neuesten Beschränkungen auf dem Gebiete der Logik bei den Deutschen*, 1880; Harnus, *Geschichte der Logik*, 1881; Venn, *Symbolic Logic*, 1881 (introduction, and pp. 305-411), a valuable contribution to the history and bibliography of the application of symbolic methods in logic. The only good bibliography of logic is that given by Rabus in his *Logik u. Metaphysik*, I. pp. 453-518. Some of the older works, e.g., Lipenius, *Bibliotheca Realis* (1685), s. vv. "Logica," "Organon," "Dialectica," contain great store of bibliographical references. A complete bibliography is a desideratum.

#### NOTE B.

*Hindu Systems of Logic.*—In almost all the Hindu systems of philosophy, as these are classified by the most recent authorities, indications are to be found of a more or less developed analysis of the process or method of reasoning, and therefore of a certain amount of logical theory. In two systems in particular the logical element is the most prominent feature. The *Nyāya*, or logical doctrine of Gotama, is in a very special sense the Hindu logic, while in the *Vaiśeṣika*, or Atomist system of Kanada, there are many expansions of or additions to the *Nyāya*, though the prevailing interest is not logical.

The most accessible sources of information regarding the Hindu logic, Colebrooke's *Essays*, and Professor M. Müller's abstracts (in the appendix to Archbishop Thomson's *Laws of Thought*), tend to mingle in an undesirable fashion what is special to the *Nyāya* doctrine, and what is added by Kanada and his followers. In order to appreciate the extent to which the analysis of reasoning has been carried in these early systems, it is advisable to restrict attention to the original exposition of the *Nyāya*.

The aim of *Nyāya* is the attainment of perfection, of bliss, through knowledge. But, to have knowledge in a systematic and complete fashion, it is requisite that the individual should know (or should be capable of organizing

<sup>1</sup> The same fact has been regarded to formal logic of the Kantian school, e.g., in Mansel's distinction of psychological and logical judgments. *Apor.*, p. 797.

his knowledge in reference to) the sixteen great topics or heads of discussion. These, as enumerated by Gotama are—(1) proof; (2) the objects of proof; (3) doubt; (4) motive; (5) the illustration or example for discussion; (6) the final assertion; (7) the enumeration of the five members of the final assertion; (8) confirmatory argument; (9) the conclusion, the defined judgment; (10) the objection; (11) controversy; (12) deceptive counter argument; (13) apparent reason or sophism; (14) fraud or wilfully deceptive argument, ruse; (15) futile argument or self-contradictory counter argument; (16) conclusive refutation. Inspection of these at once shows that they represent stages in dialectic or in the process of clearing up knowledge by discussion. The generalia, i.e., the kinds of proof, described as four in number—sense-perception, inference (either from cause to effect, from effect to cause, or from community of nature, i.e., in a wide sense, analogy), comparison (analogy in a stricter significance), tradition,—and the things about which proof may be exercised, under which a twelvefold division is given by Gotama, and enlarged in endless detail by his commentators, who introduce thereunder much of Kanada's system, are first laid down as the basis for the whole. Then follows (Nos. 3-6) the progress from doubt, which first calls for reasoning or proof, through motive, to position of the problem in the form of an example or case, and to the general assertion, as having valid grounds. The analysis of the grounds of assertion is then given, and here we have what corresponds more particularly to the syllogism as known to us. Five members are signalized.—(1) the thesis or proposition to be proved; (2) the reason, or intermediate ground by which the subject of the proposition is linked on to an explanatory principle; (3) the explanatory principle; (4) the application of this explanatory principle; (5) the statement of the conclusion as following from the application. Thus, in the example usually given—(1) *thesis*, this mountain is fiery; (2) *intermediate ground*, because it smokes; (3) *explanatory principle*, whatever smokes is fiery, as, for instance, a hearth; (4) *application*, therefore this mountain is fiery; (5) *statement of conclusion*, the mountain, then, is fiery, because it smokes. There can be no doubt that in this somewhat unsystematic arrangement we have the outlines of syllogistic argument. Considerable obscurity, however, rests over the third member, and it is only partially cleared up when we proceed to the next topic, which may perhaps be translated confirmatory argument. Here the essence of the argument appears to be a regress from the known mark to the fundamental quality from which it follows. Thus, e.g., if it were said the mountain is not fiery, then the argument would be adduced, but the mountain smokes, and what is not fiery does not smoke. Apparently there is involved the assumption that the mark is a necessary consequence of the primary quality, but the exposition is obscure, and, doubtless, connects itself with the principles of causal connexion recognized by Hindu thinkers. (See Williams, as below, pp. 73-4).

When the conclusion has thus been confirmed, when the negation of the ground has been shown to fail in explaining the observed fact, the thesis may be stated in an absolute and definitive form (topic 9). The remaining seven topics are then concerned with the discussion which may arise when an opponent brings forward objections to the conclusion. This he must do by positing his antithesis (10), whereupon issue may be joined (11). Should the adversary be unable to establish his antithesis, he may resort to deceit, bringing forward arguments, illogically arranged and devoid of force (12), which soon leads to the employment of sophisms (13) or merely apparent arguments, and even to deceitful ruses (14). Under these topics the *Nyāya* signalizes and discusses various well-known forms of fallacy. The destruction of all these fallacious arguments reduces the opponent to the employment of futile, irrelevant responses, which undermine his own position (15), and the exposure of which completes his discomfiture and reduces him to silence (16).

Expositions of this dialectic system are not yet available in such kind and amount as would enable one to do full justice to it. Evidently much patience and a very considerable knowledge of the current philosophical view would be requisite in order to appreciate at their true worth many apparently formal,

and in some cases dubious, divisions. Of accounts which may be consulted the following seem the more important.—Cudebrooke's *Essays on the Religion and Philosophy of the Hindus*, from which the expositions in Ritter (*Gea. d. Phil.*, iv. 382 sq.), Hegel (*Wetke*, xii. 161-167), and Cousin (*Histoire Générale*, lxxviii. 1) are taken; Ward's *Account of the History, Literature, and Religion of the Hindus* (4 vols. 1-11, later editions, with title altered, in 1815, 1817, 1821); Windischmann, *Philosophie im Fortgang der Weltgeschichte* (1841), specially pp. 1895-1920; M. Müller, appendix to Thompson's *Laos of Thought*; Rosenkranz, *Die Modificationen der Logik* (1840), pp. 184-97; Williams, *Indian Wisdom*, pp. 71-85; St. Hillan, articles "Indiens," "Gotama," "Nyāya," "Kanada," in *Encyclopædie Philosophique*, and translation, with commentary, of part of Gotama's "Sūtras," in the *Mémoires de l'Académie des Sciences Morales et Politiques*, tom. iii.

## NOTE C.

*Ramus*.—The logical theories of Ramus acquired for a brief period a factitious importance from their connexion with the general revolt against Aristotelianism, and with the Protestant struggle against the Roman Catholic authority. In themselves they have no particular value, nor indeed much originality, and the exposition of them by their author, always rather literary than philosophic, adds nothing of strength or interest. In comparison with the Aristotelian analysis of the nature and methods of thinking, the few alterations of statement, and generally the thin technical or logical theory, which characterize Ramist work, appear as singularly insignificant. Nor have any of the special peculiarities of the Ramist logic exercised influence on the history of logical doctrines. The keenness of the controversy which raged in so many of the centres of learning between the Aristotelians and the total or partial Ramists is explicable only as having reference to differences which were merely symbolized by the apparent difference in logical doctrine.

In the Protestant universities and seminaries generally the Ramist logic obtained, and for some time kept a firm footing. In Scotland, through Melville, Buchanan, and the earl of Murray, who had been pupil of Ramus, his system was installed as the orthodox staple of logical training, and such records as remain of Scottish university education during the troubled 16th century would undoubtedly exhibit the traces of this new movement. In England, Cambridge alone, always disposed to reject the authority of Aristotle, and generally more open to new ideas than the sister university, was a stronghold of Ramism, and, apart from special works of Ramist tendency, the adherence of the new doctrine is discernible in the writings of more than one Cambridge alumnus. William Temple, a friend of Sir Philip Sidney, and an official of the university, published a volume of *Scholæ in Rami Doctrinam*, 1601; George Downing, professor of logic, wrote commentaries *In Petri Rami Dialecticam*, 1606; and Milton, in 1672, expanded the *Dialectica* in his *Artis Logice Phœnix Instaurata*. Marlow's *Parvus*, and his *Massacre of St Bartholomew*, show how familiar Ramist phraseology and the personality of Ramus must have been to an alumnus of Cambridge, while Bacon, with well-aimed objection to much of the Ramist method, expounds the system of logic with unmistakable tolerance to the Ramist principles and method of arrangement. There is a monograph on Bacon's Ch. Waddington with a good bibliography, *Ramus (Pierre de la Pucelle) sa Vie, ses Œuvres, ses Opinions*, Paris, 1866, and a shorter work, mainly biographical, by Ch. Desmazes (*P. Ramus, Professeur au Collège de France, sa Vie, ses Œuvres, et Mort*, 1872, Paris, 1864). In Epiphanius (*Glossæ ad Rami, s. v. "Ramus"*) will be found a long list of writings for and against the Ramist logic. The history of the movement is also given in Buhle (*Gesch. d. neueren Phil.*, ii. 690-702), Tschirnhaus (*Gesch. d. Phil.*, iv. pp. 170-42), Du Fouilly (*His. Univ. Paris*, tom. iv.), Guvier (*His. de l'Univ. de Paris*, vol. i.), in Jo. Holmannus ab Hsrich (*Schœdæmonia de veteri Aristotelis in scholæ Protestantum doctrina*, §§ 21-29), De Launoy (*De Vitiis Aristot.*, in *Acad. Paris, jurtuna*, cap. xii.), and in Bayle (*Dictionnaire*, s. v. "Ramus"). (R. AD.)

**LOGOS.** This term is one of the most constant factors in ancient speculation. As it is double-sided, however, expressing both *reason* and *word*, the conceptions which it covers differ widely. Taken broadly the doctrine of the Logos may be said to have run in two parallel courses—the one philosophical, the other theological; the one the development of the Logos as reason, the other the development of the Logos as word; the one Hellenic, the other Hebrew.

1. To the Greek mind, which saw in the world a κόσμος, it was natural to regard the world as the product of reason, and reason as the ruling principle in the world. So we find a Logos doctrine more or less prominent from the dawn of Hellenic thought to its eclipse. It rises in the realm of physical speculation, passes over into the territory of ethics and theology, and makes its way through at least three well-defined stages. These are marked off by the names of Heraclitus of Ephesus, the Stoics, and Philo.

It acquires its first importance in the theories of Heraclitus. There it is intimately associated with the dominant ideas of a flux in all things, and of fire as the material substrate or primary form of existence. On the one hand the Logos is identified with γῶμη and connected with δίκη, which latter seems to have the function of correcting deviations from the eternal law that rules in things. On the other hand it is not positively distinguished either from the ethereal fire, or from the εἰσπαρένη and the ἀνάγκη according to which all things occur. In consistency with his hylozoic doctrine Heraclitus holds that nothing material can

be thought of without this Logos, but he does not conceive the Logos itself to be immaterial. Whether it is regarded as in any sense possessed of intelligence and consciousness is a question variously answered. But there is most to say for the negative. This Logos is not one above the world or prior to it, but in the world and inseparable from it. Man's soul is a part of it. It is *relation*, therefore, as Schleiermacher expresses it, or reason, not speech or word. And it is objective, not subjective, reason. The process of transition between opposites, in which all things are involved, is a process according to orderly relations and definite measures, and the Logos is the eternal principle of this world-process which shows itself in the form of a constant conflict between opposites. Like a law of nature, objective in the world, it gives order and regularity to the movement of things, and makes the system rational.<sup>1</sup>

Between Heraclitus and the Stoics comparatively little was done in developing a special Logos doctrine. With Anaxagoras a conception entered which gradually triumphed over that of Heraclitus, namely, the conception of a supreme, intellectual principle, not identified with the world but independent of it. This, however, was νοῦς, not Logos. In the Platonic and Aristotelian systems, too, the Logos appears. But it is subordinate to other more distinctive conceptions, and lacks the definiteness of a doctrine. With Plato the term selected for the expression of the principle

<sup>1</sup> Cf. Schleiermacher's *Heraclitus der Dunkle*, &c.; Bernays's *Heraclitus*; Gladisch's *Heraclitus und Zoroaster*.

to which the order visible in the universe is due is *νοῦς* or *σοφία*, not *λόγος*. It is in the pseudo-Platonic *Epinomis* that *λόγος* appears as a synonym for *νοῦς*. In Aristotle, again, the principle which sets all nature under the rule of thought, and directs it towards a rational end, is *νοῦς*, or the divine spirit itself; while *λόγος* is a term with many senses, used as more or less identical with a number of phrases, οὕτως, ἐνέργεια, ἐντελέχεια, οὐσία, εἶδος, μορφή, &c.

With the Stoics, however, the Logos doctrine reappears in great breadth. It is a capital element in their system. With their teleological views of the world they naturally predicated an active principle in connexion with it, living in it and determining it. This operative principle is called both Logos and God. It is conceived of as material, and is described in terms used equally of nature and of God. There is at the same time the special doctrine of the *λόγος σπερματικός*, the seminal Logos, or the law of generation in the world, the principle of the active reason working in dead matter. This parts into *λόγοι σπερματικοί*, which are akin, not to the Platonic ideas, but rather to the *λόγοι ἑνολοι* of Aristotle. In man, too, there is a Logos which is his characteristic possession, and which is *ἐνδιάθετος*, as long as it is a thought resident within his breast, but *προφορικός* when it is expressed as a word. This distinction between Logos as *ratio* and Logos as *oratio*, so much used subsequently by Philo and the Christian fathers, had been so far anticipated by Aristotle's distinction between the *ἔσω λόγος* and the *λόγος ἐν τῇ ψυχῇ*. The Logos of the Stoics is a reason in the world gifted with intelligence, and analogous to the reason in man.<sup>1</sup>

In the period between the Stoics and Philo there are few names of distinct interest in this connexion. But in the Alexandrian philosophy the Logos doctrine assumes a leading place, and shapes a new career for itself. The chief representative of this school is the Hellenized Jew, Philo (born about 25 B.C.). With him God is absolute and incorporeal perfection, apprehensible only by reason, and incapable of contact with matter. An intermediate agent, therefore, is affirmed, the Logos or idea of ideas. This Logos is not eternal in the sense in which God is eternal, but has its being from Him. It is His elder son, as the world is His younger. It resides with God as His wisdom, and is in the world as the divine reason. It is God's instrument in creation and in revelation. Both in the world and in man it is twofold. In man it subsists as the *λόγος ἐνδιάθετος* or immanent reason, and as the *λόγος προφορικός* or uttered reason. In the case of the world there is the Logos which has its residence with the archetypal ideas, and there is the Logos which appears in the form of many *λόγοι* or rational germs of things material. Philo's doctrine is moulded by three forces—Platonism, Stoicism, and the Old Testament. His Logos is the representative of the world to God as well as of God to the world. It is described as the "image of God" (*εἰκὼν θεοῦ*, i. 6) and the "archetypal man" (*ὁ κατ' εἰκόνα ἀνθρώπος*, i. 427), as the "son of God" and the "high priest" (*ὑποχρεῖς*, i. 653), as the "first-born son" (*πρωτόγονος*, i. 414), the "man of God" (*ἄνθρωπος θεοῦ*, i. 411), &c. It wavers all the while between attribute and substance, between the personal and the impersonal.

In the later developments of Hellenic speculation nothing essential was added to the doctrine of the Logos. Philo's distinction between God and His rational power or Logos in contact with the world was generally maintained by the eclectic Platonists and Neo-Platonists. By some of these this distinction was carried out to the extent of predicating (as was done by Numenius of Apamea) three Gods:—the supreme God; the second God, or Demiurge or Logos;

and the third God, or the world. Plotinus explained the *λόγος* as constructive forces, proceeding from the ideas and giving form to the dead matter of sensible things (*Enneads*, v. 1, 8, and Richter's *Neu-Plat. Studien*).

2. The doctrine of the Logos in Hellenic thought thus remains substantially a doctrine of the Logos as reason. The other side, the doctrine of the Logos as word, belongs as essentially to Hebrew thought. The roots of this conception lie in the Hebrew Scriptures. The God who is made known in the Old Testament is one who reveals Himself actively in history. He is exhibited, therefore, as speaking, and by His word communicating His will. The word of the God of revelation is represented as the creative principle (Gen. i. 3; Psalm xxxiii. 6), as the executor of the divine judgments (Hosea vi. 5), as healing (Psalm cvii. 20), as possessed of almost personal qualities (Isaiah lv. 11; Psalm cxlvii. 15). Along with this comes the doctrine of the angel of Jehovah, the angel of the covenant, the angel of the presence, in whom God manifests Himself, and who is sometimes identified with Jehovah or Elohim (Gen. xvi. 11, 13; xxxii. 29–31; Exod. iii. 2; xiii. 21), sometimes distinguished from Him (Gen. xxii. 15, &c.; xxiv. 7; xxviii. 12, &c.), and sometimes presented in both aspects (Judges ii. vi; Zech. i.). To this must be added the doctrine of Wisdom, given in the books of Job and Proverbs. As the Word of God is represented in the theocratic sections of the Old Testament as the creative principle of the world, so Wisdom appears with somewhat similar functions in these books. At one time it is exhibited as an attribute of God (Prov. iii. 19). At another it is strongly personified, so as to become rather the creative thought of God than a quality (Prov. viii. 22). Again it is described as proceeding from God as the principle of creation and objective to Him. In these and kindred passages (Job xv. 7, &c.) it is on the way to become hypostatized.

The Hebrew conception is partially associated with the Greek in the case of Aristobulus, the predecessor of Philo, and, according to the fathers, the founder of the Alexandrian school. He speaks of Wisdom in a way reminding us of the book of Proverbs. The pseudo-Solomonic *Book of Wisdom* (generally supposed to be the work of an Alexandrian flourishing somewhere between Aristobulus and Philo) deals both with the Wisdom and with the Logos. It fails to hypostatize either. But it represents the former as the framer of the world, as the power or spirit of God, active alike in the physical, the intellectual, and the ethical domain, and apparently objective to God. Points of affinity between the Hellenic and Hebrew conceptions are also seen in the books of Maccabees (see, e.g., 2 Macc. iii. 38). In these instances, however, and even in Philo, the Hebrew elements are only partially grasped and appropriated. In the Targums, on the other hand, the three doctrines of the word, the angel, and the wisdom of God converge in a very definite conception. In the Jewish theology God is represented as purely transcendent, having no likeness of nature with man, and making no personal entrance into history. Instead of the immediate relation of God to the world the Targums introduce the ideas of the *Mēmra* (word) and the *Shekhinā*. This *Memra*, or, as it is also designated, *Dibbārā*, is an hypostasis that takes the place of God when direct intercourse with man is in view. In all those passages of the Old Testament where anthropomorphic terms are used of God, the *Memra* is substituted for God. The *Memra* proceeds from God, and retains the creaturely relation to God. It does not seem to have been identified with the Messiah.<sup>2</sup>

<sup>1</sup> Cf. especially Zeller's *Phil. der Gr.*, 2d ed., vol. iii.; or Reiche's translation, *The Stoics, Epicureans, and Sceptics*.

<sup>2</sup> Cf. the Targum of Onkelos on the Pentateuch under Gen. vii. 16, xvii. 2, xxi. 20; Exod. xix. 16, &c.; the Jerusalem Targum on Numb. vii. 89, &c.

The Hebrew Logos and the Old Testament doctrine reach their climax in the prologue to John's Gospel. The three conceptions of the active Word, the Angel, and the Wisdom of God, which had been fused in the Rabbinical idea of a Memra, meet there in the final grandeur of the Word of God incarnate. The question of the *genesis* of the Johannine doctrine has been greatly debated. There is a remarkable similarity between John's terms and Philo's. But this is due mainly to the fact that John and Philo made use of the same inherited phraseology for the expression of their several doctrines. The Johannine doctrine is not derived from the Philonic. The Logos of Philo is distinctively reason; the Logos of John is Word. The one is metaphysical; the other is theological. In Philo the Logos is the divine principle that creates and sustains. In John the Logos who creates also redeems. In Philo the Logos hovers midway between the personal and the impersonal. In John he is a distinct personality. To Philo the idea of an incarnation of God is alien and abhorrent. The heart of John's doctrine is the historical fact that the Word was made flesh.

In many of the early Christian writers, as well as in the heterodox schools, the Logos doctrine is influenced by the Greek idea. The Syrian Gnostic Basilides held (according to Irenæus, i. 24) that the Logos or Word emanated from the *voûs*, or personified reason, as this latter emanated from the unbegotten Father. The completest type of Gnosticism, the Valentinian, regarded Wisdom as the last of the series of æons that emanated from the original Being or Father, and the Logos as an emanation from the first two principles that issued from God, Reason (*voûs*) and Truth. Justin Martyr, the first of the sub-apostolic fathers, taught that God produced of His own nature a rational power (*δυναμὴν τινα λογικὴν*). His agent in creation, who now became man in Jesus (*Dial. c. Tryph.*, chap. 43, 60). He affirmed also the action of the *λόγος σπερματικός* (*Apol.*, i. 46; ii. 13, &c.). With Tatian (*Cohort. ad. Gr.*, chap. 5, &c.) the Logos is the beginning of the world, the reason that comes into being as the sharer of God's rational power. With Athenagoras (*Suppl.*, chap. 9, 10) He is the prototype of the world and the energizing principle (*ἰδέα καὶ ἐνέργεια*) of things. Theophilus (*Ad Autolyce.*, ii. 10, 24) taught that the Logos was in eternity with God as the *λόγος ἐνδιάθετος*, the counsellor of God, and that when the world was to be created God sent forth this counsellor (*σύμβουλος*) from Himself as the *λόγος προφορικός*, yet so that the begotten Logos did not cease to be a part of Himself. With Hippolytus (*Refut.*, x. 32, &c.) the Logos, produced of God's own substance, is both the divine intelligence that appears in the world as the Son of God, and the idea of the universe immanent in God. The early Sabellians (comp. Euseb., *Hist. Eccl.*, vi. 33; Athan., *Contra Ariam.*, iv.) held that the Logos was a faculty of God, the divine reason, immanent in God eternally, but not in distinct personality prior to the historical manifestation in Christ. Origen, referring the act of creation to eternity instead of to time, affirmed the eternal personal existence of the Logos. In relation to God this Logos or Son was a copy of the original, and as such inferior to that. In relation to the world he was its prototype, the *ἰδέα ὁρατὴ*, and its redeeming power (*Contra Cel.*, v. 608; *Frag. de Princip.*, i. 4; *De Princip.* i. 109, 324).

*Literature.*—In addition to the histories of philosophy (e.g., those of Ritter, Ueberweg, Zeller, &c.), the commentaries on John's Gospel (Lücke, Godet, Westcott, &c.), and the systems of Biblical theology (Oehler, Schultz, Immer, Weiss, &c.), the following writings deserve special notice:—Schürer, *Lehrb. der N.T. Zeitgeschichte*; Hausrath, *Neu-Testamentliche Zeitgeschichte*; Weyl, *Lehre vom Logos in der griechischen Philosophie*; Soulier, *La Doctrine du Logos*; Gfrörer, Philo; Siegfried, Philo; Daehne, *Geschichtliche Darstellung der jüdisch-alexandrinischen Religions-Philosophie*; Donner, *History of the Development of the Doctrine of the Person of Christ*; Huber, *Philosophie der Kirchen-väter*; Weber, *System der Alt-Synagogalen Palästinischen Theologie*; Grossmann, *Questiones Philonæ*. (S. D. F. S.)

LOGROÑO, an inland province of Spain, the smallest of the eight modern divisions of Old Castile, is bounded on the N. by Burgos, Alava, and Navarre, on the E. by Navarre and Zaragoza, on the S. by Soria, and on the W. by Burgos. The area is 1945 square miles, with a population in 1877 of 174,425. It belongs entirely to the basin of the river Ebro, which forms its northern boundary except for a short distance near San Vicente, and is now navigable throughout the entire length of the province; its drainage takes place chiefly by the rivers Tiron, Oja, Najerilla, Iregua, Leza, Cidacos, and Alhama, all flowing in a north-easterly direction. The portion skirting the

Ebro forms a spacious and for the most part fertile undulating plain, called La Rioja in its western part; but in the south Logroño is considerably broken up by offshoots from the sierras which separate that river from the Douro. In the east the Cerro de Lorenzo rises to a height of about 7725 feet, and in the south the Pico Santa Ines is upwards of 7380 feet. The mineral resources, which are believed to be considerable, are as yet undeveloped. The products of the province are chiefly cereals, good oil and wine (especially in the Rioja), fruit (except oranges and lemons), silk, flax, and honey. The industries, which are unimportant, include spinning and weaving. Logroño is traversed by the Ebro valley railway, which connects Miranda del Ebro with Zaragoza; on this line are situated all the towns of the province with a population exceeding 5000—Haro, Logroño, Calahorra, and Alfaro.

LOGROÑO, capital of the above province, is situated on the right bank of the Ebro, which is here crossed by a handsome stone bridge of twelve arches, dating from 1138; the surrounding plain is well cultivated and fertile, producing the rich Rioja wine. The city is the seat of the usual provincial authorities, civil and military. It has a theatre, and several hospitals and convents. The parish church claims great antiquity. The population in 1877 was 13,393; the trade and industries are unimportant.

The district of Logroño was in ancient times inhabited by the *Berones* or *Verones* of Strabo and Pliny, and their *lania* is to be identified with the modern suburb of the city of Logroño now known as Varea or Barea. The place fell into the hands of the Moors in the 8th century, but was speedily retaken by the Christians, and under the name of *Lucronius* appears with frequency in mediæval history. Logroño was the birthplace of the painter Navarrete (el Mudo) and of Espartero; the latter died there on January 9, 1879.

LOGWOOD is a valuable dye-wood, the product of a leguminous tree, *Hæmatoxylon campechianum*, native of Central America, and grown also in the West Indian Islands. The tree attains a height not exceeding 40 feet, and is said to be ready for felling when about ten years old. The wood, deprived of its bark and the sap-wood, is sent into the market in the form of large blocks and billets. It is very hard and dense, and externally has a dark brownish-red colour; but it is less deeply coloured within. The best qualities come from Campeachy, but it is obtained there only in small quantity. A large export trade in logwood of good quality is carried on from Honduras and Jamaica, and inferior qualities are exported from St Domingo, Martinique, Guadeloupe, &c. The wood was introduced into Europe as a dyeing substance soon after the discovery of America, but for many years (from 1581 to 1662) its use in England was prohibited by legislative enactment on account of the inferior dyes which at first were produced by its employment.

The colouring principle of logwood exists in the timber in the form of a glucoside, from which it is liberated as hæmatoxylin or hæmatin by fermentation. Hæmatoxylin was first isolated by Chevreul in 1810, and its constitution was subsequently investigated by Erdmann, who found it to have the formula  $C_{16}H_{14}O_6$ . It forms two crystalline hydrates, the principal combination being with three molecules of water. This hydrate,  $C_{16}H_{14}O_6 + 3H_2O$ , is a colourless body very sparingly soluble in cold water but dissolving freely in hot water and in alcohol. By exposure to the air, especially in alkaline solutions, hæmatoxylin is rapidly oxidized into hæmatein, with the development of a fine purple colour. The reaction consists in the elimination of two atoms of hydrogen, thus: hæmatoxylin hydrate ( $C_{16}H_{14}O_6 + 3H_2O$ ) + O = hæmatein ( $C_{16}H_{12}O_6 + 3H_2O$ ) +  $H_2O$ . This reaction of hæmatoxylin is exceedingly rapid and delicate, rendering that body a valuable laboratory test for alkalies. It is remarkable that the difference of two atoms of hydrogen between colourless hæmatoxylin and coloured hæmatein is precisely that which exists between the white and the blue forms of indigo. By the action of hydrogen and sulphurous acid, hæmatein is easily reduced to hæmatoxylin.

Logwood is prepared for use by dyers, &c., in the form of chips and raspings, and as a solid brittle black extract. Chipped logwood is moistened with water and spread in thin layers till a gentle fermentation sets up, whereby, under the influence of liberated ammonia, hæmatoxylin is formed from the glucoside. By exposure to the air, through repeated turnings of the mass, hæmatein is developed from the hæmatoxylin, and the chips gradually become coated with the brilliant metallic green crystals of hæmatein. Logwood extract, largely used in calico printing, is obtained from oxidized chips and raspings by lixiviation, the solution being concentrated at as low a temperature as possible.

The principal use of logwood is for dyeing wool and woollen goods, on which it produces, with various mordants, shades of blue from a light lavender to a dense blue-black, according to the amount of logwood used. It is more employed in combination with other dye-stuffs than as the sole tinctorial agent, the best and most permanent blacks on wool, known as woaded blacks, being first dyed blue in the indigo vat, and finished black with logwood and bichromate of potash. In calico-printing logwood is used to produce steam purples, for the production of which the calico is mordanted with stannate of soda, and printed with a strong solution of logwood extract thickened with starch. By steaming, the hæmatein of the logwood combines with binoxide of tin precipitated in the fibre, and thus develops a bright purple colour. Logwood blacks, which are a standard product of print works, are produced by mordanting with iron liquor, passing the calico through a logwood solution, and developing and fixing the colour by treatment with a weak solution of bichromate of potash. Logwood blacks assume a bright red tint by the action of dilute acids, a test by which they can readily be distinguished from aniline and other fast blacks. Logwood is also largely used in the preparation of ink (*q.v.*), and to a small extent in medicine. The imports of logwood into the United Kingdom during the year 1880 amounted to 69,280 tons, the estimated value of which was £192,392.

LOHÁRDAGÁ, or LOHARDUGGA, a district in the lieutenant-governorship of Bengal, India, between 22° 20' and 24° 39' N. lat. and 83° 22' and 85° 56' E. long., is bounded on the N. by Hazáribágh and Gayá, on the N.W. and W. by Mirzápur district and Sargájá and Jashpur states, and on the S.E. and E. by Sinhbhum and Manbhum districts. It comprises Chutiá Nágpur proper, and the Palámau subdivision. Chutiá Nágpur is an elevated table-land, forming the central and south-eastern portion of Lohárdagá district; its surface is undulating, and the slopes of the depressions lying between the ridges are cut into terraces covered with rice. Palámau, which forms the north-western portion of the district, consists on the east and south of spurs thrown off from the plateaus of Hazáribágh and Chutiá Nágpur, while the remainder of the tract is a tangled mass of isolated peaks and long irregular stretches of broken hills. The average elevation of Palámau is about 1200 feet above sea-level, but some peaks rise to over 3000 feet. This part of the district contains no level areas of any extent, except the valleys of the North Koel and Amánat rivers, to which rice cultivation is confined. The principal rivers of Lohárdagá are the Subarnarekhá and the North and South Koel. The entire district was probably at one time overgrown with dense forest, but the forest area has been continually dwindling, owing to the spread of cultivation and the practice of girdling the *sal* trees for resin.

The census of 1872 disclosed a total population of 1,237,123 (621,548 males and 615,575 females), spread over an area of 12,044 square miles; of these only 91 were returned as Europeans and 3 as of mixed race. The racial element is very strongly represented—the Mundas numbering 163,051; Kols, 132,104; and Uraons, 151,810. The most numerous among the semi-aboriginal tribes are the Bhils, 15,008; Khawars, 33,573; Bhogtás, 8,472; and Dosáhts, 3,223. The Hindus number 741,952, and Mohammedans 58,211. The Christian population is larger than in any other Bengal district, except the metropolitan one of the

Twenty-four Parganás. In 1872 the total Christian population numbered 12,781, of whom 12,687 were natives, nearly all belonging to the aboriginal tribes of Mundas and Uraons. Most of them are poor, but they possess considerable influence, and are rising in public esteem. The two missions are the German Lutheran and Church of England, which successfully work together side by side. The population is entirely rural, Ranchi town (12,086) being the only place with more than 5000 inhabitants. Rice forms the staple crop; other crops are wheat, barley, Indian corn, millets, peas, gram, oilseeds, *pán*, cotton, and tobacco. Opium cultivation was introduced in 1869, and in 1874-75 yielded 245 cwts. There are two small tea plantations. Mildew and blights occasionally attack the crops; droughts seldom affect any considerable area. The principal trading place is Garwá in Palámau. Stick lac, resin, catechu, silk cocoons, hides, oil-seeds, *ghát*, cotton, and iron are here collected for exportation; while rice and other food grains, brass vessels, piece goods, blankets, broad cloth, silk, salt, tobacco, spices, drugs, and beads are brought to market for local consumption. The manufactures consist of shell-lac, inferior articles of brass and iron work, coarse cloth, blankets, mats, baskets, rope, and rude pottery. Iron, lime, and soapstone are worked in small quantities; gold is washed by the poorer classes from the sands of the rivers. An important coal-bearing tract, known as the Daltonganj coal-field, covers an area of nearly 200 square miles, and lies partly in the valley of the Koel river, and partly in that of the Amánat. The net revenue of the district in 1870-71 was £29,900, and the expenditure £22,563. The schools in 1876-77 numbered 303, with 8088 pupils. The climate of the table-land of Chutiá Nágpur is said to be superior to that of any other part of India, except the lower ranges of the Himalayas. The hot weather extends over almost six weeks, commencing about the 20th April, but is never really oppressive. The rainy season lasts from the middle of June to about the first week in October. The principal diseases are malarious fever and rheumatism of a severe type.

LOIRE (Lat., *Liger*), the first of the rivers of France in length of course (626 miles) and extent of basin (44,979 square miles), has its headwaters in the great central plateau, and is considered to take its rise in the Gerbier de Jone, in the department of Ardèche, at a height of 4504 feet above the sea,—though the Allier branch, which has its source about 30 miles west, in the department of Lozère, at the foot of Maure de la Gardille, 4668 feet above the sea, has an almost equal course. The two streams continue to run parallel till the upper Loire turns westward and is joined by the Allier in the neighbourhood of Nevers. All the more important affluents of the upper and middle part of the Loire—as the Cher, the Indre, the Vienne, respectively 198, 152, and 231 miles in length—have their gathering grounds in the central plateau. In the north east the basin of the Seine comes so close (at one place to within 6 or 7 miles) that the versant towards the Loire has hardly anything to contribute; and it is not till within 65 miles of the estuary that we find an important tributary, the Maine, bringing down the drainage of the Brittany plateau. At certain seasons the Loire is navigable for ships as far as Nantes (33 miles), for boats as far as La Noirie (other 518 miles), and for rafts as far as Retournac; but for six months of the year navigation is practically impossible.

In the volume of water there is all the irregularity of a mountain torrent; at the Bec d'Allier, for instance,—the meeting point of the two head streams,—while the maximum current is 953,200 cubic feet per second, the minimum is 10,600 cubic feet, and above Orleans the range lies between 31,800 and 850. During the drought of summer thin and feeble streams thread their way between the sandbanks of the channel; while at other times a stupendous flood pours down and submerges wide reaches of land. In the middle part of its course the Loire traverses the western portion of the undulating Paris basin, with its Tertiary marls, sands, and clays, and the alluvium carried off from these renders its lower channel inconstant; the rest of the drainage area is occupied by crystalline rocks, over the hard surface of which the water, undiminished by absorption, flows rapidly into the streams. A fall of from 3 to 4 inches over the whole river basin is sufficient to pour 35,320,000,000 cubic feet of water into the channels. When the rain is general over the whole area, the floods on the different tributaries reach the main river at different times; but when, through any cause, two or more of them arrive at the same time, inundations of the most serious character result. Attempts to control the river must have begun at a very early date, and by the close of the Middle Ages the bed between Orleans and Angers was enclosed by dykes 10 to 13 feet high. L.

1783 a double line of dykes or *turcies* 23 feet high was completed from Bec d'Allier downwards. This great work had, however, the serious defect that the channel was so much narrowed that the embankments are almost certain to give way as soon as the water rises 16 feet (the average rise is about 14, and in 1846 it was more than 22). In more modern times the importance of the water-way from the sea to Nantes led to the embanking of the lower part of the course; but instead of a depth of 16 feet being secured, as the engineers anticipated, there is no more at full tide than 13 feet. One of the practical results of this state of matters has been the commercial development of Saint Nazaire and Paimboeuf, and the comparative decline of Nantes as a great shipping port. Besides the general embankments of the river, several of the towns along the Loire have constructed special works to defend themselves against the floods; Tours, the most exposed of all, is surrounded by a circular dyke. Various schemes for the systematic regulation of the Loire have been discussed. It has been proposed to construct in the upper valleys of the several affluents a number of gigantic dams or reservoirs from which the water, stored during flood, could be let off into the river as required. A reservoir of this kind, formed by the engineer Mathieu at the village of d'Inay, about 18 miles above Roanne, and capable of retaining from 3500 to 4500 million cubic feet of water, has greatly diminished the force of the floods at Roanne, and maintained the comparative equilibrium of the current during the dry season. There is a canal (157 miles) along the left bank of the Loire between Roanne and Briare, and the Canal du Berri connects this with the navigable part of the Cher. The Canal du Centre extends from Digoin on the Loire to Chalon on the Saône; the Canal du Nivernais and the canals starting from Orleans and Briare communicate with the Seine; and the Nantes canal opens up the way to Lorient, Brest, and Dinan. The canals of the Saultre and the Dive (20 and 26 miles respectively) are mainly for irrigation purposes.

See H. Blerzy, *Torrents, Fleuves, et canaux de la France* (Paris, 1878), and his papers in *Rev. des Deux Mondes*, February and March 1875.

LOIRE, a department of central France, made up of the old district of Forez and portions of Beaujolais and Lyonnais, all formerly included in the province of Lyonnais, lies between 45° 15' and 46° 15' N. lat. and between 3° 10' and 4° 45' E. long., and is bounded on the N. by the department of Saône-et-Loire, on the E. by those of Rhône and Isère, on the S. by Ardèche and Haute-Loire, and on the W. by Puy de Dôme and Allier. Its extreme length is 78 miles from north-west to south-east, and its extreme breadth from east to west is about 43 miles, the area being 1838 square miles. Until 1790 it constituted a single department along with that of Rhône. About an eighth part of the whole area belongs to the basin of the Rhône. The Loire, which has a fall within the department from 1365 feet to 386 feet, traverses alternately a series of narrow gorges and of broad plains, the beds of ancient lakes, including that of Forez between St Rambert and Fours, and, lower down, that of Roanne. Of its affluents the most important are the Lignon du Nord, the beautiful valley of which has been called "La Suisse Forezienne," and the Aix on the left, and on the right the Ondaine (on which stand the industrial towns of Chambon-Féugerolles and Firminy), the Furens, and the Rhin. To the Rhône the department contributes the Gier, upon which are situated the industrial towns of St Chamond and Rive de Gier, and which forms a navigable channel to the Rhône at Givors. From Mont Pilat descends the Doâne, in the valley of which the workshops of Annonay begin. In the west are the Forez mountains, which separate the Loire basin from that of the Allier; their highest point (Pierre sur Haute, 5381 feet) is 12 miles west from Montbrison. They sink gradually towards the north, and are successively called Bois Noirs (4239 feet), from their woods, and Mouts de la Madeleine (3600 to 1640 feet). In the east the Rhône and Loire basins are separated by Mont Pilat (4705 feet) at the north extremity of the Cévennes, and by the hills of Lyonnais, Tarare, Beaujolais, and Charolais, none of which rise higher than 2950 or 3280 feet. The climate of the department varies according to the elevation: on the heights it is cold and healthy, unwholesome in the marshy plain of Forez, mild in the valley of the Rhône. The

annual rainfall is 39.37 inches on the Forez mountains, but only 24.79 at Roanne. More than half of the area consists of arable lands; one-seventh is occupied by forests, and one-seventh by meadows.

The plains of Forez and Roanne are the two most important agricultural districts, but the total production of grain within the department is insufficient for the requirements of the population. The pasture lands of Forez support a large number of horned cattle, sheep, goats, and pigs. Fairly good red wine is also grown within the department; potatoes, numerous plants, beetroot, hemp, and colza are also cultivated. Poultry are reared, and bee-keeping is a considerable industry. Among the hills replantation has been set on foot. The Bois Noir forests yield good-sized pines and large quantities of wood for mining purposes. The so-called Lyons chestnuts are to a large extent obtained from Forez; the woods and pasture lands of Pilat yield medicinal plants, such as mint. The chief wealth of the department, however, lies in the coal deposits in the St Etienne basin, the second in importance in France. The basin, which stretches from south-west to north-east between Firminy and Rive de Gier, is about 20 miles in length and 5 in breadth. In 1881 the output amounted to 3,451,612 tons of coal and anthracite, giving employment to 12,000 workmen below and 5000 above. The presence of coal has naturally encouraged various forms of the metal-working industries. At St Etienne there is a national factory of arms, in which as many as 6000 have been employed; apart from other factories of the same kind carried on by private individuals, the production of hardware occupies 7000 persons; locks, common cutlery, chain cables for the mines, files, and nails are also made. Cast steel is largely manufactured, the aggregate production of all sorts of steel amounting in 1880 to 114,629 tons; the Loire workshops supply the heaviest constructions required in naval architecture. The glass industry has its centre at Rive de Gier. St Etienne employs more than 60,000 persons in the fabrication of silk ribbons, to an annual value of 24,000,000; over and above this must be reckoned the manufacture of elastic ribbons and laces, and the dressing of raw silks. The arrondissement of Roanne manufactures cotton stouts upon 11,000 looms, each employing three persons. That of Montbrison produces table linen. In the mountains between Haute-Loire and Puy de Dôme the women make black laces and embroidery. The department has numerous flour-mills, paper works, tanneries, boat-building yards, silk-spinning works, and velvet, plush, and hat factories. There are three arrondissements—St Etienne, Montbrison, and Roanne. The capital is St Etienne. The population, 290,903 in 1801, was 520,613 in 1876.

LOIRE, HAUTE, a department of central France, made up of Velay and portions of Vivarais and Gévaudan, three districts formerly belonging to the old province of Languedoc, of a portion of Forez formerly belonging to Lyonnais, and of a portion of lower Auvergne, is bounded on the N. by Puy de Dôme and Loire, on the E. by Loire and Ardèche, on the S. by Ardèche and Lozère, and on the W. by Lozère and Cantal, and lies between 41° 40' and 15° 25' N. lat. and between 3° 5' and 1° 30' E. long., having an extreme length of 68 miles, a maximum breadth of 54 miles, and an area of 1916 miles. It belongs almost wholly to the Loire basin, but a few square kilometres to the north of Mont Mézenc are drained by the Erioux, a tributary of the Rhône. The highest point, Mont Mézenc, on the borders of Ardèche, is 5745 feet; it belongs to the Cévennes system, which sends ramifications throughout the entire department, giving it a mean altitude of 2950 feet. Reckoning from east to west are the Bontières, the Mégol or Meygal, the Velay hills, those of La Margeride, and finally the Jauguet. The first mentioned ridge separates Haute-Loire from Ardèche, and ranges from 3280 to 1590 feet; it has a crust of lava thrown out from Mont Mézenc; efforts towards replantation are being made. Meygal presents a series of jagged peaks, recalling the Pyrenees on a small scale. It also has been covered by an immense flow of lava some 37 miles long and 190 feet thick, through which the Loire has forced a passage by means of gorges more than 1600 feet in depth. The highest point of the Meygal properly so called is upwards of 1590 feet. The Velay hills, which separate the Loire from the Allier (mean height about 3300 feet), consist of granitic rocks overlaid with the eruptions of more than one hundred and fifty craters, one of which

is now occupied by the singular lake of Bouchet. Westward from the Allier are the forest-clad granitic hills of La Margeride, which rise to a height of nearly 6000 feet. The Lugnet massif (3300 feet) rises in the north-west of the department on the left bank of the Alagnon, a tributary of the Allier. The river Loire, to which the department owes its name, enters at a point 16 miles distant from its source, and 2923 feet above the level of the sea. Within the 63 miles of its course through the eastern portion of the department, first in a northerly and afterwards in a north easterly direction, it falls 1565 feet. The Allier, which joins the Loire at Nevers, traverses the western portion of Haute-Loire in a northerly direction, entering at a point 25 miles distant from its source, and 2369 feet above the sea; it traverses a narrow and deep valley overhung by lofty hills, and falls 1090 feet. The chief affluents of the Loire within the limits of the department are the Borne on the left, joining it near Puy, and the Lignon, which descends from the Mézenc, between the Boutières and Meygal ranges, on the right. The climate, owing to the altitude, the northward direction of the valleys, and the winds from the Cevennes, is cold, the winters being long and rigorous. Storms and violent rains are frequent on the higher grounds, and would give rise to serious inundations were not the rivers for the most part confined within deep rocky channels. Two-fifths of the area is occupied by arable lands, one-fifth by natural meadow and by orchards, and a somewhat smaller proportion by wood. The rest consists of pasture lands, vineyards, and uncultivated lands.

Numerous cattle of the celebrated Mézenc breed are reared, and also sheep and mules. The crops raised are wheat, meslin, rye, barley, oats, maize, potatoes (in large quantity), hemp, colza, and second-class wine. The woods yield pine, fir, oak, and beech. Large quantities of aromatic and pharmaceutical plants are found in the Mézenc massif. The department has two coal basins,—those of Brassac and Langeac, both on the Allier; in 1880 their total output was 225,153 tons. Copper, iron, zinc, argentiferous lead, arsenic, antimony, barytes, and fluor spar are also obtained, and there are good quarries of trachyte and limestone, as well as numerous unutilized mineral springs. Lace-making in various materials is the most extensive industry, occupying from 100,000 to 130,000 persons, and producing goods to the annual value of about £1,000,000. Ribbons and cloth are manufactured to some extent, and silk-dressing, wool-spinning, caoutchouc-making, various kinds of smith work, paper-making, glass-blowing, brewing, wood-sawing, and flour-milling are also carried on. There are three arrondissements—Puy, Brioude, and Yssingeaux; the capital is Puy. The population in 1876 was 313,721.

LOIRE-INFÉRIEURE, a maritime department of western France, is made up of a portion of Brittany on the right and of the district of Retz on the left of the Loire, and lies between 46° 45' and 47° 40' N. lat. and between 55° and 2° 32' W. long., being bounded on the W. by the ocean, on the N. by Morbihan and Ille-et-Vilaine, on the E. by Maine-et-Loire, and on the S. by Vendée. Its greatest length from east to west is 76 miles, its greatest breadth 65 miles, and its area 2654 square miles. The surface is very flat, and the highest point, in the north on the borders of Ille-et-Vilaine, is only 377 feet. The line of hillocks skirting the right bank of the Loire, and known as the "sillon de Bretagne," nowhere attains a height of 265 feet; below Savenay they recede from the river, and the meadows give place to peat bogs. North of St Nazaire the Grande Briere, measuring 9 miles by 6, and rising scarcely 10 feet above the sea-level, still supplies old trees which can be used for joiner work; a few scattered villages occur on the more elevated spots, but communication is effected chiefly by means of the canals which intersect it. The district on the south of the Loire lies equally low; its most salient feature is the lake of Grandlieu, covering an area of 27 square miles, and surrounded by low and marshy ground, but so shallow (6·5 feet at most) that

drainage would be comparatively easy. The Loire has a course of 68 miles within the department; its width above Nantes varies from 1300 to 3280 feet, and its volume at Nantes, where the tide begins to be felt, is never under 700 cubic metres per second. It has numerous islands. At Paimbœuf it is nearly 2 miles broad, but narrows again opposite St Nazaire before finally entering the ocean. The bed is not sufficiently regular to allow easily the passage of vessels drawing more than 10 feet of water. On the left bank a canal of 9 miles is about to be opened between Pellerin, where the dikes which protect the Loire valley from inundation terminate, and Paimbœuf. The principal towns on the river within the department are Ancenis, Nantes, and St Nazaire (one of the most important commercial ports of France), on the right, and Paimbœuf on the left. The chief affluents are on the right the Erdre and on the left the Sèvre, both debouching at Nantes. The Erdre has a succession of broad lakes which give it the appearance of a first class river; it forms part of the canal from Nantes to Brest. The Sèvre, on the other hand, is hemmed in by picturesque hills; at the point where it enters the department it flows past the famous castle of Clisson. Apart from the Loire itself, the only navigable channel of importance within the department is the Nantes and Brest canal already referred to, fed by the Isac, a tributary of the Vilaine, which separates Loire-Inférieure from Ille-et-Vilaine and Morbihan. The climate partakes of the general Armorican character in respect of humidity, but is Girondine in its mildness. At Nantes the mean annual temperature is 54°·7 Fahr., and there are one hundred and twenty-two rainy days, the annual rainfall being 25·6 inches. Of the entire area nearly two-thirds is arable; one-seventh is occupied by meadows; and vineyards, woods, heath, lakes, pools, and marshes occupy the remainder.

The quantity of live stock is considerable:—320,000 horned cattle, 180,000 sheep, 80,000 pigs, 88,000 horses, asses, and mules. Poultry also is reared, and there is a good deal of bee-keeping. Wheat, rye, buckwheat, oats, and potatoes are produced in great abundance; leguminous plants are also largely cultivated, especially near Nantes. Beetroot, hemp, and chestnuts represent, along with wine and cider, the chief remaining agricultural products. The woods are of oak in the interior and pine on the coast. The department has deposits of tin, lead, and iron, which are hardly wrought, if at all. North-west from Ancenis a little anthracite is obtained from a coal-bed which is a prolongation of that of Anjou. The salt marshes, about 6000 acres in all, occur for the most part between the mouth of the Vilaine and the Loire, and on the Bay of Bourgneuf. The salt manufacture, which as late as 1874 produced 43,475 tons, is now decaying. There are slate quarries in the north-east of the department, and the granite of the sea-coast and of the Loire up to Nantes is quarried for large blocks, while the limestone about Châteaubriant occupies numerous kilns. The industries of the department are well developed: steam-engines are built for Government at Indret, a few miles below Nantes; the forges of Basse-Indre are in good repute for the quality of their iron; and the production of the lead-smelting works at Couéron amounts to several millions of francs annually. There are also considerable foundries at Nantes, Chantenay, and St Nazaire, and shipbuilding yards at Nantes, St Nazaire, Paimbœuf, and Croisic. Among other industries may be mentioned the preparation of pickles and preserved meats at Nantes, the curing of sardines at Croisic and in the neighbouring communes, salt-refining, the great sugar refinery at Nantes, and the tobacco manufacture also there. Fishing is prosecuted along the entire coast. Nantes, formerly one of the most important of French ports, has now given way before St Nazaire, the trade of which in 1878 exceeded 1,500,000 tons. The principal imports are coal, colonial wares, wood, metals, manure; the exports are wine, salt, preserved meats and pickles, flour, refined sugar, and butter. The department is divided into five arrondissements—Nantes, Ancenis, Châteaubriant, Paimbœuf, and St Nazaire; Nantes is the capital. The population in 1876 was 612,972, an increase of 243,667 since 1801.

LOIRET, a department of central France, made up of three districts of the ancient province of Orléanais,—Orléanais proper, Gâtinais, and Dunois,—together with portions of the Isle of France and Berri, lies between

30° and 48° 20' N. lat. and between 1° 30' and 3° 8' E. long., and is bounded on the N. by Seine-et-Oise, on the N.E. by Seine-et-Marne, on the E. by Yonne, on the S. by Nièvre and Cher, on the S.W. by Loir-et-Cher, and on the N.W. by Eure-et-Loir; its greatest length, from north-west to south-east, is 75 miles, its greatest breadth, from north to south along the meridian of Paris, 50 miles, and its area 2614 square miles. The name is derived from the Loiret, a stream which issues from the ground some miles to the south of Orleans, and after a course of about 7 miles falls into the Loire; its large volume gives rise to the belief that it is a subterranean branch of that river. The Loire traverses the department by a broad valley which, though frequently devastated by disastrous floods, is famed for its rich tilled lands, its castles, its towns, and its vine-clad slopes. To the right of the Loire are Gâtinais (capital Montargis) and Beauce; the former district is so named from its *gâtines* or wildernesses, of which saffron is, along with honey, the most noteworthy product; Beauce, on the other hand, a monotonous tract of corn-fields without either tree or river, has been called the granary of France. Between Beauce and the Loire is the extensive forest of Orleans, which is slowly disappearing before the advances of agriculture. South of the Loire is Sologne, long barren and unhealthy from the impermeability of its subsoil, but undergoing gradual improvement in both respects by means of pine plantation and draining and manuring operations. The surface of the department presents little variation of level; the highest point (on the borders of Cher) is 900 feet above the level of the sea, and the lowest (on the borders of Seine-et-Marne) is 220 feet. The watershed on the plateau of Orleans between the basins of the Seine and Loire, which divide Loiret almost equally between them, is almost imperceptible. The lateral canal of the Loire from Roanne stops at Briare; from the latter town a canal connects with the Seine by the Loing valley, which is joined by the Orleans canal at Montargis. The only important tributary of the Loire within the department is the Loiret; the Loing, a tributary of the Seine, has a course of 40 miles from south to north, and is accompanied throughout first by the Briare canal and afterwards by that of Loing. The Essonne, another important affluent of the Seine, entering Loiret at Malaherbes, takes its rise on the plateau of Orleans, as also does its tributary the Juine. The department has the climate of the Seguanian region, the mean temperature being almost the same as that of Paris; the number of rainy days is one hundred and twenty, and the rainfall varies from 18·5 to 27·5 inches according to the district, that of the exposed Beauce being smaller than that of the woody Sologne. Two-thirds of the entire area is cultivable; between one-sixth and one-seventh is under wood; vineyards occupy one-twentieth; and the remainder is taken up by meadows, heath, and marsh.

A large number of sheep, cattle, horses, asses, pigs, and goats are reared; poultry, especially geese, and bees are plentiful. The yield of wheat and oats is much in excess of the consumption; the crops of rye, barley, meslin, potatoes, beetroot, colza, and hemp are also very important. Wine is abundant, but of inferior quality. Buckwheat supports bees by its flowers, and poultry by its seeds. Saffron is another source of wealth. The woods consist of oak, elm, birch, and pine; fruit trees thrive in the department, and Orleans is a great centre of nursery gardens. The industries are brick and tile making, and the manufacture of fustian, for which Gien is one of the most important centres in France. The Briare manufacture of porcelain buttons and pearls employs 1500 workmen. Flour-mills are very numerous. There are iron and brass foundries, which, along with agricultural implement making, bell-founding, and the manufacture of pipes, nails, and files, represent the chief metal-working industries. The production of hosiery, wool-spinning, and various forms of wool manufacture are also engaged in. A large quantity of the wine grown is made into vinegar (*vinaigre d'Orléans*). The tanneries produce excellent leather; and paper-making, sugar-refining, wax-bleaching, and the manufacture of caoutchouc (in one factory) complete the list of industries. The exports are principally

corn, flour, wine, vinegar, live-stock, and wood. The four arrondissements are those of Orleans, Gien, Montargis, and Pithiviers. The capital is Orleans. The population in 1876 was 360,903 an increase of 70,764 since 1801.

LOIR-ET-CHER, a department of central France, consists of a small portion of Touraine, but chiefly of portions of Orléanais proper, Blésois, and Dunois, districts which themselves formerly belonged to Orléanais. It lies between 47° 11' and 48° 8' N. lat. and between 0° 35' and 2° 15' E. long., and is bounded on the E. by Eure-et-Loir, on the N.E. by Loiret, on the S.E. by Cher, the S. by Indre, on the S.W. by Indre-et-Loire, and on the N.W. by Sarthe, the greatest length (north-west to south-east) being 78 miles, maximum breadth 31 miles, and the area 2452 miles. Its name is derived from the Loir and the Cher, by which it is traversed in the north and in the south respectively. The Loire divides it into two nearly equal portions, the district on the right of the Loire being known as Beauce, while that on the right of the Loir again is called Perche; on the left of the Loire is Sologne. The surface of Perche is varied, and reaches a maximum height of 840 feet; its woods alternate with hedged fields and orchards, and rapid rivulets water the green valleys. Beauce is a rich agricultural country, where the monotony of the endless fields of corn is broken only by the houses grouped together in villages, or by the stacks which surround them. Sologne was formerly a region of forests, of which that of Chambord is one of the last remains. Its soil, formerly barren and unhealthy, has been considerably improved within recent years. The Cher and Loir traverse pleasant valleys, occasionally bounded by walls of tufa, in which numerous dwellings have been excavated; the stone extracted, after hardening by exposure to the air, has been used for building purposes in the nearer towns. Within the department the Loir has a course of 56 miles, the Cher of 50, and the Loire of 37. With the help of the Berri canal the last-mentioned is navigable throughout. The chief remaining rivers of the department are the Beuvron, which flows into the Loire on the left, and the Sauldre on the right of the Cher. All these named have a south westerly course, following the slope of the department. The climate is temperate and mild, and healthy if Sologne be left out of account. The mean temperature ranges between 52° and 53° Fahr., and the rainfall is 25·4 inches. Of the total area more than a half is arable; one-sixth is under wood, and one-sixth is waste; vineyards, meadows, and pasture lands occupy the remainder.

Sheep are extensively reared, and the Perche breed of horses is much sought after for its combination of lightness with strength. There are more than twenty thousand beehives within the department. Beauce is the most productive district; in 1878 it yielded 342,000 quarters of wheat, 556,000 of oats, and 1,500,000 bushels of potatoes, besides meslin, rye, barley, buckwheat, beetroot, maize, colza, and hemp. In the same year the production of wine amounted to 27,000,000 gallons, the most valuable being that of Cote du Cher. The forests are an important source of wealth. Sologne supplies pine and birchwood for furnace fuel, and in the neighbourhood of Blois there are oak, elm, and chestnut plantations. In the river valleys fruit trees and nursery gardens are numerous. Formerly the speciality of Loir-et-Cher was to supply Europe with gun flints. Building stones, and also clay for bricks and pottery, are also abundant. The chief industries are the manufacture of cloth at Romorantin (where spinning, ribbon-making, and tanning are also carried on), of white leather and gloves at Vendôme, distilling, glass-making, paper-making, pottery-making, and the like. The exports are wine, brandy, vinegar, wood, cloth, wool, leather, grain, legumes, wax, and leeches. Of the castles which adorn the department the finest and most famous is that of Chambord, near the left bank of the Loire opposite Blois (the capital). The three arrondissements are those of Blois, Romorantin, and Vendôme. In 1876 the population was 272,634, an increase of 55,721 since 1801.

LOJA, or LOXA, a town of Spain, in the province of Granada, lies in a beautiful valley through which flows the Genil, here crossed by a Moorish bridge, about 33 miles

by rail west from Granada. The situation is very steep, and the streets in consequence are extremely crooked and irregular. The castle stands on a rock in the centre of the town, which, from being the key to Granada, was once a place of great military importance. The manufactures of Loja consist chiefly of coarse woollens, silk, paper, and leather. Salt is obtained in the neighbourhood. The population in 1877 was 18,249.

Loja, which has sometimes been identified with the ancient *Lepida*, or with the *Laubi* (*Laubis*) of Pliny and Ptolemy, first clearly emerges in the Arab chronicles of the year 890. It was taken by Ferdinand III. in 1226, but was soon afterwards abandoned, and did not finally fall under the arms of Castile until May 28, 1486, when it surrendered to Ferdinand and Isabella after a siege.

LOKEREN, a town of Belgium, in the province of East Flanders and district of Termonde, on the Durme (a small but navigable stream by which it communicates with the Scheldt), and 11 miles from Ghent on the railway to Antwerp, which is there joined by the lines to Termonde and Alost, and to Selzete. It is a busy manufacturing place, with cotton factories, ropewalks, and bleach-works, &c. The church of St Lawrence (17th century) has a fine pulpit, representing Jesus in the midst of the doctors. The population of the commune has increased from 11,960 in 1808 to 17,400 in 1876.

LOKMÁN, a name famous in Arabian tradition. The Arabs distinguish two persons of this name. The older Lokmán was an Adite, and is said to have built the famous dyke of Ma'rib. He not only escaped the destruction sent on his nation for their refusal to hear the prophet Húd, but received the gift of a life as long as that of seven vultures, each of which is said to have lived eighty years.<sup>1</sup> The other Lokmán, called "Lokmán the Sage," is mentioned in the Koran (xxxi. 11). He is said to have been a Nubian slave, son of 'Anká, and to have lived in the time of David in the region of Elah and Midian (Masúdy, i. 110), but the commentators on the Koran (Abu Sa'úd, ii. 336) make him son of Bá'úra, the son of Job's sister or daughter. This form of the legend, and many of the stories told of him (D'Herbelot, s.v., but not those given by Nawawy, p. 526), show Jewish influence on the legend, and Derenbourg (*Fables de Lokmán le sage*, 1850) has pointed out that Bá'úra seems to be identical with Beor, and that Lokmán corresponds to Balaam, the roots of both names meaning "to swallow," so that the one may be viewed as a translation of the other. In favour of this identification Derenbourg advances several important and probably conclusive arguments from Jewish tradition; but in view of the divergent accounts given of Lokmán it may be questioned whether Jewish influence created or only modified the Arabic tradition. The grave of Lokmán was shown on the east coast of the Lake of Tiberias, but also in Yemen and elsewhere (Yakút, iii. 512; D'Herbelot, s.v.).

The name of Lokmán is associated with numerous old verses, parables, and anecdotes of which Freytag, *Arabum Proverbia*, gives many examples. The fables which pass under his name, and were first printed by Epimenius (Leyden, 1615), are not mentioned by any Arabic writer. They appear to be of Christian origin, and are mainly derived, though not closely copied, from those of Syntipas and JE. They existed in the 13th century (Derenbourg, *op. cit.*). The citations are numerous, the book having been much used as an elementary Arabic reading-book. Those of Rodiger (2 vols. 1869, with glossary) and Derenbourg (1850) claim special mention.

LOLLARDS, There were the English followers of John Wicliffe, and were the adherents of a religious movement which was widespread in the end of the 14th and begin-

ning of the 15th centuries, and which to some extent maintained itself on to the Reformation. The name is of uncertain origin: it has been traced to a certain Walter Lollard, but he was probably a mythical personage; some derive it from *lolum*, tares, quoting Chaucer (*C. T.*, Shipman's Prologue)—

"This Lollere here wol prechen us somewhat . . .  
He wolde sowen some difficulte  
Or sprengen cokklo in oure clene corn;"

but the most generally received explanation derives the words from *lollen* or *lullen*, to sing softly. The word is much older than its English use; there were Lollards in the Netherlands as early as the beginning of the 14th century, who were akin to the Fratricelli, Beghards, and other sectaries of the recusant Franciscan type. The earliest official use of the name in England occurs in 1387 in a mandate of the bishop of Worcester against five "poor preachers," *nomine seu ritu Lollardorum confederatos*. It is probable that the name was given to the followers of Wicliffe because they resembled those offshoots from the great Franciscan movement which had disowned the pope's authority and separated themselves from the mediæval church. The 14th century, so full of varied religious life, made it manifest that the two different ideas of a life of separation from the world which in earlier times had lived on side by side within the mediæval church were irreconcilable. The church chose to abide by the idea of Hildebrand and to reject that of Francis of Assisi; and the revolt of Ockham and the Franciscans, of the Beghards and other spiritual fraternities, of Wicliffe and the Lollards, were all protests against that decision. Hildebrand's object was to make church government or polity in all respects distinct from civil government—no civil ruler to touch churchman or church possession for trial or punishment, taxation or confiscation; and, in the hands of his successors who followed out his principles, the church became transformed into an empire in rivalry with the kingdoms, and of somewhat the same kind, only that its territories were scattered over the face of Europe in diocesan domains, convent lands, or priests' glebes, its taxes were the tithes, its nobles the prelates. Francis of Assisi had another ideal. Christians, he thought, could separate themselves from the world, in imitation of Christ, by giving up property, and home, and country, and going about doing good and living on the alms of the people. For a time these two ways of separation from the world lived on side by side in the church, but they were really irreconcilable; Hildebrand's church required power to enforce her claims, and money, land, position, were all sources of power. Church rulers favoured the friars when they found means of evading their vows of absolute poverty, and gradually there came to be facing each other in the 14th century a great political Christendom, whose rulers were statesmen, with aims and policy of a worldly ambitious type, and a religious Christendom, full of the ideas of separation from the world by self-sacrifice and of participation in the benefits of Christ's work by an ascetic imitation, which separated itself from political Christianity and called it anti-Christ. Wicliffe's whole life was spent in the struggle, and he bequeathed his work to his followers the Lollards. The main practical thought with Wicliffe was that the church, if true to her divine mission, must aid men to live that life of evangelical poverty by which they could be separate from the world and imitate Christ, and if the church ceased to be true to her mission she ceased to be a church. Wicliffe was a metaphysician and a theologian, and had to invent a metaphysical theory—the theory of *Dominium*—to enable him to transfer, in a way satisfactory to himself, the powers and privileges of the church to his company of poor Christians; but his

<sup>1</sup> Tabary, i. 240; Abulk., *H. A.*, 20; Dandry, ii. 324. The tradition has various forms. Masúdy, iii. 366, 375, gives Lokmán only the age of one century. Further details are given by Causin de Perceval, *Écrits*. The virtues of Lokmán, especially the seventh, whose name was also used in other parts of Arabian poetry and proverbs.

followers, who were not troubled with need of theories, were content to allege that a church which held large landed possessions, collected tithes greedily, and took money from starving peasants for baptizing, burying, and praying, could not be the church of Christ and his apostles, who in poverty went about doing good.

Lollardy was most flourishing and most dangerous to the ecclesiastical organization of England during the ten years after Wickliffe's death. It had spread so rapidly and grown so popular that a hostile chronicler could say that almost every second man was a Lollard. Wickliffe left three intimate disciples:—Nicholas Hereford, a doctor of theology of Oxford, who had helped his master to translate the Bible into English; John Ashton, also a fellow of an Oxford college; and John Purvey, Wickliffe's colleague at Lutterworth, and a co-translator of the Bible. With these were associated more or less intimately, in the first age of Lollardy, John Parker, the strange ascetic William Smith, the restless fanatic Swynderly, Richard Waytstraet, and Crompe; and there must have been a large number of preachers who itinerated through England preaching the doctrines of their master. Wickliffe had organized in Lutterworth an association for sending the gospel through all England, a company of poor preachers somewhat after the Wesleyan method of modern times. "To be poor without mendicancy, to unite the flexible unity, the swift obedience of an order, with free and constant mingling among the poor, such was the ideal of Wickliffe's 'poor priests'" (cf. Shirley, *Rasc. Ziz.*, p. xl.), and, although proscribed, these "poor preachers," with portions of their master's translation of the Bible in their hand to guide them, preached all over England wherever they could be heard without detection. The Oxford university and many nobles supported them. Lord Montacute, Lord Salisbury, Sir Thomas Latimer of Braybrooke, and several others had chaplains who were Lollardist preachers; whilst many merchants and burgesses assisted the work with money. The organization must have been strong in numbers, but only the names of those have come down to us who were seized for heresy, and it is only from the indictments of their accusers that their opinions can be gathered. The preachers were picturesque figures in long russet dress down to the heels, who, staff in hand, preached in the mother tongue to the people in churches and graveyards, in squares, streets, and houses, in gardens and pleasure grounds, and then talked privately with those who had been impressed. The Lollard literature was very widely circulated,—books by Wickliffe and Hereford and tracts and broadsides,—in spite of many edicts proscribing it. In 1395 the Lollards grew so strong that they petitioned parliament through Sir Thomas Latimer and Sir H. Stury to reform the church on Lollardist methods. It is said that the Lollard Conclusions printed by Canon Shirley (p. 360) contain the substance of this petition. If so, parliament was told that temporal possessions ruin the church and drive out the Christian graces of faith, hope, and charity; that the priesthood of the church in communion with Rome was not the priesthood Christ gave to his apostles; that the monk's vow of celibacy had for its consequence unnatural lust, and should not be imposed; that transubstantiation was a feigned miracle, and led people to idolatry; that prayers made over wine, bread, water, oil, salt, wax, incense, altars of stone, church walls, vestments, mitres, crosses, staves, were magical and should not be allowed; that kings should possess the *ius episcopale*, and bring good government into the church; that no special prayers should be made for the dead; that auricular confession made to the clergy, and declared to be necessary for salvation, was the root of clerical arrogance and the cause of indulgences and other abuses in pardoning sin; that all wars

were against the principles of the New Testament, and were but murdering and plundering the poor to win glory for kings; that the vows of chastity laid upon nuns led to child murder; that many of the trades practised in the commonwealth, such as those of goldsmiths and armourers, were unnecessary and led to luxury and waste. These Conclusions really contain the sum of Wickliffe's teaching; and, if we add that the principal duty of priests is to preach, and that the worship of images and going on pilgrimages are sinful, they include almost all the heresies charged in the indictments against individual Lollards down to the middle of the 15th century. The king, who had hitherto seemed anxious to repress the action of the clergy against the Lollards, spoke strongly against the petition and its promoters, and Lollardy never again had the power in England which it wielded up to this year.

If the formal statements of Lollard creed are to be got from these Conclusions, the popular view of their controversy with the church may be gathered from the ballads preserved in the collection of *Political Poems and Songs relating to English History*, published in 1859 by Mr Thomas Wright for the Master of the Rolls series, and in the *Piers Ploughman* poems. *Piers Ploughman's Creed* (see LANGUAGE) was probably written about 1391, when Lollardy was at its greatest strength; the ploughman of the *Creed* is a man gifted with sense enough to see through the trick of the friars, and with such religious knowledge as can be got from the creed, and from Wickliffe's version of the Gospels. The poet gives us a "portrait of the fat friar with his double chin shaking about as big as a goose's egg, and the ploughman with his hood full of holes, his mittens made of pitches, and his poor wife going barefoot on the ice so that her blood followed" (*Early English Text Society*, vol. xxx., pref., p. 16); and one can easily see why farmers and peasants turned from the friars to the poor preachers. The *Ploughman's Complaint* tells the same tale. It paints popes, cardinals, prelates, rectors, monks, and friars, who call themselves followers of Peter and keepers of the gates of heaven and hell, and pale poverty stricken people, cotless and landless, who have to pay the fat clergy for spiritual assistance, and asks if these are Peter's priests after all. "I trowe Peter took no money, for no sinners that he sold. . . . Peter was never so great a fole, to leave his key with such a losell."

In 1399 the Lancastrian Henry IV. overthrew the Plantagenet Richard II., and one of the most active partisans of the new monarch was Arundel, archbishop of Canterbury and the most determined opponent of Lollardy. It has been alleged that Henry won his help by promising to do his utmost to suppress the followers of Wyclif, and this much is certain, that when the house of Lancaster was firmly established upon the throne the infamous Act *De comburendo hereticos* was passed in 1400, and church and state combined to crush the Lollards. John Purvey was seized; William Santrey (Chartris) was tried, condemned, and burned. The Lollards, far from daunted, abated no effort to make good their ground, and united a struggle for social and political liberty to the hatred felt by the peasants towards the Romish clergy. Jak Upland (John Countryman) took the place of Piers Ploughman, and upbraided the clergy, and especially the friar, for their wealth and luxury. Wickliffe had published the rule of St Francis, and had pointed out in a commentary upon the rule how far friars had departed from the maxims of their founder, and had persecuted the *Spirituals* (the Fratricelli, Beghards, Lollards of the Netherlands) for keeping them to the letter (cf. Matthews, *English Works of Wyclif hitherto unprinted*, Early Eng. Text Soc., vol. lxxiv., 1880). Jak Upland put all this into rude nervous English verse:—

"Freer, what charitie is this  
To faim that whoso liveth after your order  
Liveth most perfectlie,  
And next followeth the state of the Apostles  
In povertie and penance:  
And yet the wisest and greatest clerkes of you  
Wend or send or procure to the court of Rome,  
. . . and to be assailed of the vow of povertie."

The archbishop, having the power of the state behind him, attacked that stronghold of Lollardy the university of Oxford. In 1406 a document appeared bearing to be the testimony of the university in favour of Wickliffe; its genuineness was disputed at the time, and when quoted by Huss at the council of Constance it was repudiated by the English delegates. The archbishop treated Oxford as if it had issued the document, and procured the issue of severe regulations in order to purge the university of heresy. In 1408 Arundel in convocation proposed and carried the famous *Constitutiones Thomae Arundel* intended to put down Wickliffite preachers and teaching. They provided amongst other things that no one was to be allowed to preach without a bishop's licence, that preachers preaching to the laity were not to rebuke the sins of the clergy, and that Lollard books and the translation of the Bible were to be searched for and destroyed. He next attempted to purge the nobility of Lollardy. The earlier leaders had died, but there was still one distinguished Lollard, Sir John Oldcastle, in right of his wife Lord Cobham, "the good Lord Cobham" of the common people, who had been won to pious living by the poor preachers, and who openly professed the common Lollard doctrines. His chaplain, one of the itinerating preachers, was seized, then his books and papers were taken and burnt in the king's presence, and later he was indicted for heresy. It is said that at first he recanted, but the abjuration, said to be his, may not be authentic. In the end he was burnt for an obstinate heretic. These persecutions were not greatly protested against; the wars of Henry V. with France had awakened the martial spirit of the nation, and little sympathy was felt for men who had declared that all war was but the murder and plundering of poor people for the sake of kings. Mocking ballads were composed upon the martyr Oldcastle, and this dislike to warfare was one of the chief accusations made against him (comp. Wright's *Political Poems*, vol. ii. p. 244). But Arundel could not prevent the writing and distribution of Lollard books and pamphlets. Two appeared just about the time of the martyrdom of Oldcastle—*The Ploughman's Prayer* and the *Lanthorne of Light*. *The Ploughman's Prayer* declared that true worship consists in three things—in loving God, and dreading God, and trusting in God above all other things; and it showed how Lollards, pressed by persecution, became further separated from the religious life of the church. "Men maketh now great stonewall houses full of glazen windows, and clepeth thilke thine houses and churches. And they setten in these houses mawmets of stocks and stones, to fore them they knelen privilych and apert and maken their prayers, and all this they say is they worship. . . . For Lorde our belief is that thine house is man's soul."

The council of Constance (1414–1418) put an end to the papal schism, and also showed its determination to put down heresy by burning John Huss. When news of this reached England the clergy were incited to still more vigorous proceedings against Lollard preachers and books. From this time Lollardy appears banished from the fields and streets, and takes refuge in houses and places of concealment. There was no more wayside preaching, but instead there were *conventicula occulta* in houses, in peasants' huts, in sawpits, and in field ditches, where the Bible was read and exhortations were given, and so

Lollardy continued. In 1428 Archbishop Chichele confessed that the Lollards seemed as numerous as ever, and that their literary and preaching work went on as vigorously as before. It was found out also that many of the poorer rectors and parish priests, and a great many chaplains and curates, were in secret association with the Lollards, so much so that in many places processions were never made and worship on saints' days was abandoned. For the Lollards if not stamped out were hardened by persecution, and became fanatical in the statement of their doctrines. Thomas Bagley was accused of declaring that if in the sacrament a priest made bread into God, he made a God that can be eaten by rats and mice; that the pharisees of the day, the monks, and the nuns, and the friars, and all other privileged persons recognized by the church were limbs of Satan; and that auricular confession to the priest was the will not of God but of the devil. And others held that any priest who took salary was excommunicate; and that boys could bless the bread as well as priests.

From England Lollardy passed into Scotland. Oxford infected St Andrews, and we find traces of more than one vigorous search made for Lollards among the teaching staff of the Scottish university, while the Lollards of Kyle in Ayrshire were claimed by Knox as the forerunners of the Scotch Reformation.

The opinions of the later Lollards can best be gathered from the learned and unfortunate Peacock, who wrote his elaborate *Repressor* against the "Bible-men," as he calls them. He summed up their doctrines under eleven heads: they condemn the having and using images in the churches, the going on pilgrimages to the memorial or "mynde places" of the saints, the holding of landed possessions by the clergy, the various ranks of the hierarchy, the framing of ecclesiastical laws and ordinances by papal and episcopal authority, the institution of religious orders, the costliness of ecclesiastical decorations, the ceremonies of the mass and the sacraments, the taking of oaths, and the maintaining that war and capital punishment are lawful. When these points are compared with the Lollard Conclusions of 1395, it is plain that Lollardy had not greatly altered its opinions after fifty-five years of persecution. All the articles of Peacock's list, save that on capital punishment, are to be found in the Conclusions; and, although many writers have held that Wickliffe's own views differed greatly from what have been called the "exaggerations of the later and more violent Lollards," all these views may be traced back to Wickliffe himself. Peacock's idea was that all the statements which he was prepared to impugn came from three false opinions or "trowings," viz., that no governance or ordinance is to be esteemed a law of God which is not founded on Scripture, that every humble minded Christian man or woman is able without "fail and default" to find out the true sense of Scripture, and that having done so he ought to listen to no arguments to the contrary; he elsewhere adds a fourth (vol. i. p. 102), that if a man be not only meek but also keep God's law he shall have a true understanding of Scripture, even though "no man ellis tocho him saue God." These statements, especially the last, show us the connexion between the Lollards and those mystics of the 14th century, such as Tauler and Ruysbroeck, who accepted the teachings of Nicholas of Basel, and formed themselves into the association of the Friends of God.

The question remains—What was the connexion between the Lollard movement and the Reformation in England? Many writers make Lollardy the forerunner of Reformation teaching; others, like Mr Gairdner, relying on the facts that the persecution of the Lollards did not rouse the English nation in the way that the martyrdom of Huss excited the Bohemians and that Lollardy had almost faded out of sight in the beginning of the 16th century, admit only a casual connexion between the two awakenings. The problem is scarcely one which can be settled by counting the numbers of Lollards convicted at different periods from the beginning to the end of the 15th century, or by pointing to the enthusiasm or indifference of the mass of the English nation to Lollard doctrines. The English Reformation down to the middle of Elizabeth's reign was much more a political than a religious movement with "the great proportion of English people." Lollardy in its most essential and invariable characteristics had much more in common with mediæval religious revivals than with Reformation piety, and Lollard preaching must have had much more resemblance to that of Ockham and his recussant Franciscans than that of Luther, Calvin, or Peter Martyr. But Lollardy did one thing for England which other mediæval revivals did not do for the lands in which they

arose; it made the Bible familiar to the people in their mother tongue, and this must have been a positive preparation for the English Reformation of no ordinary power. May not the great peculiarity of the English Reformation on its religious side, the repeated attempts to give a good version of the Bible from the original tongues into English, by Tyndale, Coverdale, Taverner, Crammer, the Genevan refugees, and Parker, with the revisions and combinations of these various translations, on to our present authorized version, have come from the fact that Lollard Bible-men, as Peacock calls them, had made a good English Bible a necessity for an English reformation of religion?

**LOMBARD, PETER** (c. 1100–1160), bishop of Paris, better known as *Magister Sententiarum*, the son of obscure parents, was born about the beginning of the 12th century, at Novara (then reckoned as belonging to Lombardy). After receiving his education in jurisprudence and the liberal arts at Bologna, he removed to France, bearing a recommendation to Bernard of Clairvaux, who first placed him under Lotolf at Rheims, and afterwards sent him to Paris with letters to Gilduin, the abbot of St Victor. His diligence and talents soon brought him into notice, and ultimately obtained for him a theological chair, which he held for a number of years; during this period he is said to have been the first to introduce theological degrees. On June 29, 1159, he succeeded his former pupil, Philip, brother of Louis VII., in the bishopric of Paris, but did not long survive the promotion; according to the most trustworthy of the meagre accounts we have of his life, he died on July 20 of the following year.

His famous theological handbook, *Sententiarum Libri Quatuor*, is, as the title implies, primarily a collection of "sententiæ patrum." These are arranged (professedly on the basis of the aphorism of Augustine, Lombard's favourite authority, that "omnis doctrina vel rerum est vel signorum") into four books, of which the first treats of God, the second of the creature, the third of the incarnation, the work of redemption, and the virtues, and the fourth of the seven sacraments and eschatology. It soon attained immense popularity, ultimately becoming the text-book in almost every theological school, and giving rise to endless commentaries. A charge of heresy ("nihilianism") was indeed raised against Lombard for a particular view which he seemed not remotely to have indicated regarding Christ's human nature, but neither at the synod of Tours, where the question was first broached in 1163, nor at the subsequent Lateran synod in 1179, does a condemnation seem to have been obtained. In 1300 the theological professors of Paris agreed in the rejection of sixteen propositions taken from Lombard, but their decision was far from obtaining universal currency.

Besides the *Sententie*, Lombard wrote numerous commentaries (e.g., on the Psalms, Canticles, Job, the Gospel Harmony, and the Pauline Epistles), sermons and letters, which still exist in MS. The *Glossæ seu Commentarius in Psalmos Davidis*, first published at Paris in 1533, and the *Collectanea in omnes D. Pauli Epistolas* (Paris, 1535) have been reprinted by Migne.

**LOMBARDS.** The history of the Lombards falls into three divisions:—(1) The period before the invasion in 568 A.D.; (2) the Lombard kingdom in Italy between 568 and 774; (3) the period of their incorporation with the Italian population, and the history of Lombardy and its cities as one of the great provinces of Italy—(a) from the restoration of the empire under Charles the Great (800) to the peace of Constance with Frederick Barbarossa (1183), and (b) from the declaration of independence to the time of the tyrannies and, afterwards, of the French, Spanish, and Austrian rule.

1. The name *Lombard* is the Italianized form of the national name of a Teutonic tribe, *Langobardi*, itself an Italian arrangement, based on a supposed etymology of the Teutonic *Langbard*, *Langobard*, the form used when they are first named by Roman writers—Velleius and Tacitus. The etymology which made the name mean *Longbeard* is too obvious not to have suggested itself to Italians, and

perhaps to themselves (see Zeuss, 95, 109); it is accepted by their first native chronicler, Paul the Deacon, who wrote in the time of Charles the Great. But the name has also been derived from the region where they are first heard of. On the left bank of the Elbe, "where Börde or Bord still signifies a fertile plain by the side of a river," a district near Magdeburg is still called the *Lange Börde*; and lower down the Elbe, on the same side, about Lüneburg, the *Bardengau*, with its *Bardewik*, is still found; it is here that Velleius, who accompanied Tiberius in his campaign in this part of Germany, and who first mentions the name, places them. As late as the age of their Italian settlement the Lombards are called *Barli* in poetical epitaphs, though this may be for the convenience of metre.

Their own legends bring the tribe as worshippers of Odin from Scandinavia to the German shore of the Baltic, under the name of *Winili*, a name which was given to them in a loose way as late as the 12th century (e.g., by Ordericus Vitalis; cf. Zeuss, 57). By the Roman and Greek writers of the first two centuries of our era they are spoken of as occupying, with more or less extension at different times, the region which is now Hanover and the Altmark of Prussia. To the Romans they appeared a remarkable tribe:—"gens etiam Germana feritate ferocior," says Velleius, who had fought against them under Tiberius; and Tacitus describes them as a race which, though few in numbers, more than held their own among numerous powerful neighbours by their daring and love of war. In the quarrels of the tribes they appear to have extended their borders; in Ptolemy's account of Germany, in the 2d century, they fill a large space among the races of the north-west and north. But from the 2d century the name disappears, till it is found again at the end of the 5th century as that of a half-Christian tribe on the northern banks of the Danube. How they got there, and in what relation these Langobards bore to those who lived in the 1st and 2d centuries on the west bank of the Elbe, we learn little from the vague stories preserved by their traditions; but they are described by Procopius, a contemporary (B.G., ii. 14, 15), as subject to one of the most ferocious of the tribes on the Danube, the Heruli, also a Teutonic tribe, by whose oppression they were driven in despair to a resistance, which ended in the utter defeat and overthrow of their tyrants. We know nothing of the way in which Christianity was introduced among them, probably only among some of their noble families; but they were Arians like their neighbours and predecessors in Italy, the Goths, and like them they brought with them into Italy a hierarchy of bishops, priests, and deacons; but, while the Gothic Bible of Ulfilas is partially preserved, whatever religious literature the Langobards had in the shape of versions of the Scriptures or liturgical forms has utterly perished. They were among the Teutonic tribes which were generally on good terms with the empire, and were encouraged by it in their wars with their more barbarous neighbours. After defeating the Heruli and destroying their tribal organization, the Langobards attacked the Gepidæ with equal success, scattering the tribe or incorporating its survivors in their own host. They thus became the most formidable of the Teutonic tribes of the Danube. They had alliances with the distant Saxons, probably a kindred stock, and with the Hunnish Avars of the Danube. Their kings belonged to a royal line, and made marriages with the kings of the Franks and the other German nations. Their wars led them westwards, and for forty years they are said to have occupied Pannonia, the region between the Danube and the valleys of the Drave and Save. Thus following the line of movement of the Goths, they resolved at last to strike for

<sup>1</sup> Except in the Anglo-Saxon *Traveler's Song*, of probably between 375–435: see Guest's *English Rhythms*, ii. 77, 83, 87.

the great prize which the Goths had won and lost. Through the eastern passes, and the border land of Friuli, they invaded Italy. It is said that they were invited by Narses, the conqueror of the Goths, in revenge for his ill treatment by the masters whom he had served.

2. In 568 Alboin, king of the Langobards, with the women and children of the tribe and all their possessions, with Saxon allies, with the subject tribe of the Gepidæ, and a mixed host of other barbarians, descended into Italy by the great plain at the head of the Adriatic. There was little resistance to them. The war which had ended in the downfall of the Goths had exhausted Italy; it was followed by famine and pestilence; and the Government at Constantinople, away in the East, made but faint efforts to retain the province which Belisarius and Narses had recovered for it. Except in a few fortified places, such as Ticinum or Pavia, the Italians did not venture to encounter the new invaders; and, though Alboin was not without generosity, the Lombards, wherever resisted, justified the opinion of their ferocity by the savage cruelty of the invasion. In 572, according to the tragic tale of the Lombard chronicler, a tale which recalls the story of Candaules in Herodotus, Alboin, the fierce conqueror, fell a victim to the revenge of his wife Rosamond, the daughter of the king of the Gepidæ, whose skull Alboin had turned into a drinking cup, out of which he forced Rosamond to drink; but the Langobards had already shown themselves in ravaging bands all over Italy, and in the north had begun to take possession. Military chiefs, whom, after the Latin writers, we call "dukes," corresponding to the German "Herzog," were placed, or placed themselves, first in the border cities, like Friuli and Trent, which commanded the north-eastern passes, and then in other principal places in Italy, and this arrangement became characteristic of the Lombard settlement. The principal seat of the settlement was the rich plain watered by the Po and its affluents, which was in future to receive its name from them; but their power extended across the Apennines into Liguria and Tuscany, and then southwards to the outlying dukedoms of Spoleto and Benevento. The invaders failed to secure any maritime ports such as Genoa, Pisa, Naples, Salerno, Ravenna, or any territory that was conveniently commanded from the sea. Pavia, or, as it was called, Ticinum, the one place which had obstinately resisted Alboin, became the seat of their kings, as it had been one of the seats of the Gothic kingdom.

After the short and cruel reign of Cleph, the successor of Alboin, the Lombards (as we may begin for convenience sake to call them) tried for ten years the experiment of a national confederacy of their dukes, without any king at their head. It was the rule of some thirty-five or thirty-six petty tyrants, under whose oppression and private wars even the invaders suffered, while the Italians were remorselessly trodden under foot. With anarchy among themselves and so precarious a hold on the country, hated by the Italian population and by their natural leaders the Catholic clergy, threatened also by an alliance of the Greek empire with their natural and persistent rivals the Franks beyond the Alps, they resolved to sacrifice their turbulent independence to the usual necessities of the Teutonic invaders which led to the election of a king. In 584 they chose Authari, the grandson of Alboin, and endowed the royal domain with a half of their possessions. From this time till the fall of the Lombard power before the arms of their rivals the Franks under Charles the Great, the kingly rule continued. Authari, "the Long-haired," with his Roman title of Flavius, marks the change from the war-king of an invading host to the permanent representative of the unity and law of the nation, and the increased power of the crown, by the possession of a great

domain, to enforce its will. The independence of the dukes was surrendered to the king. The dukedoms in the neighbourhood of the seat of power were gradually absorbed, and their holders transformed into royal officers. Those of the northern marches, Trent and Friuli, with the important dukedom of Turin, retained longer the kind of independence which marchlands usually give where invasion is to be feared. The great dukedom of Benevento in the south, with its neighbour Spoleto, threatened at one time to be a separate principality, and even to the last resisted, with varying success, according to the personal characters of its dukes, the full claims of the royal authority at Pavia.

The kingdom of the Lombards lasted more than two hundred years, from Alboin (568) to the fall of Desiderius (774),—much longer than the preceding Teutonic kingdom of Theodoric and the Goths. But it differed from the other Teutonic conquests in Gaul, in Britain, in Spain. It was never complete in point of territory: there were always two, and almost to the last three, capitals—the Lombard one, Pavia, the Latin one, Rome, the Greek one, Ravenna; and the Lombards never could get access to the sea. And it never was complete over the subject race: it profoundly affected the Italians of the north; in its turn it was entirely transformed by contact with them; but the Lombards never overcame the natural repulsion of the two races, and never amalgamated with the Italians till their power as a ruling race was crushed by the victory given to the Roman element by the restored empire of the Franks. The Langobards, German in their faults and in their strength, but coarser, at least at first, than the Germans whom the Italians had known, the Goths of Theodoric and Totila, found themselves continually in the presence of a subject population very different from anything which the other Teutonic conquerors met with among the provincials,—like them, exhausted, dispirited, unwarlike, but with the remains and memory of a great civilization round them, intelligent, subtle, sensitive, feeling themselves infinitely superior in experience and knowledge to the rough barbarians whom they could not fight, and capable of hatred such as only cultivated races can nourish. The Lombards who came into Italy with the most cruel incidents of conquest, and who, when they had occupied the lands and cities of Upper Italy, still went on sending forth furious bands to plunder and destroy where they did not care to stay, never were able to overcome the mingled fear and scorn and loathing of the Italians. They adapted themselves very quickly indeed to many Italian fashions. Within thirty years of the invasion, Authari took the fancy of decking himself with the imperial title of Flavius, even while his hands were leading Italian captives in leash like dogs under the walls of Rome, and under the eyes of Pope Gregory; and it was retained by his successors. They soon became Catholics; and then in all the usages of religion, in church building, in founding monasteries, in their veneration for relics, they vied with Italians. Authari's queen, Theodelinda, solemnly placed the Lombard nation under the patronage of St John the Baptist, and at Monza she built in his honour the first Lombard church, and the royal palace near it. King Liutprand (712-744) bought the relics of St Augustine for a large sum to be placed in his church at Pavia. Their Teutonic speech disappeared; except in names and a few technical words all traces of it are lost. But to the last they had the unpardonable crime of being a ruling barbarian race or caste in Italy. To the end they are "nefandissimi," execrable, loathsome, filthy. So wrote Gregory the Great when they first appeared. So wrote Pope Stephen IV., at the end of their rule, when stirring up the kings of the Franks to destroy them. Authari's short reign (584-591) was one of renewed effort for con-

quest. It brought the Langobards face to face, not merely with the emperors at Constantinople, but with the first of the great statesmen popes, Gregory the Great (590-604). But Lombard conquest was bungling and wasteful. It was ever ready to lapse into mere plunder and warfare; and when they had spoiled a city they proceeded to tear down its walls and raze it to the ground. But Authari's chief connexion with the fortunes of his people was an important, though an accidental one. The Lombard chronicler tells us a romantic tale of the way in which Authari sought his bride from Garibald, duke of the Bavarians, how he went incognito in the embassy to judge of her attractions, and how she recognized her disguised suitor. The bride was the Christian Theodelinda, and she became to the Langobards what Bertha was to the Anglo-Saxons, and Clotilda to the Franks. She became the mediator between the Lombards and the Catholic Church. Authari, who had brought her to Italy, died shortly after his marriage. But Theodelinda had so won on the Lombard chiefs that they bid her as queen choose the one among them whom she would have for her husband and for king. She chose Agilulf, duke of Turin (592-615). He was not a true Langobard, but a Thuringian. It was the beginning of peace between the Lombards and the Catholic clergy. Agilulf could not abandon his traditional Arianism, and he was a very uneasy neighbour, not only to the Greek exarch, but to Rome itself. But he was favourably disposed both to peace and to the Catholic Church. Gregory interfered to prevent a national conspiracy against the Langobards, like that of St Brice's day in England against the Danes, or that later uprising against the French, the Sicilian Vespers. He was right both in point of humanity and of policy. The Arian and Catholic bishops went on for a time side by side; but the Lombard kings and clergy rapidly yielded to the religious influences around them, even while the national antipathies continued unabated and vehement. Gregory, who despaired of any serious effort on the part of the Greek emperors to expel the Lombards, endeavoured to promote peace between the Italians and Agilulf; and, in spite of the feeble hostility of the exarchs of Ravenna, the pope and the king of the Lombards became the two real powers in the north and centre of Italy. Agilulf was followed, after two unimportant reigns, by his son-in-law, the husband of Theodelinda's daughter, King Rothari (636-652), the Lombard legislator, still an Arian though he favoured the Catholics. He was the first of their kings who did for the Lombards what was done by all the Teutonic conquerors as soon as they felt themselves a nation on Roman soil; he collected their customs under the name of laws,—and he did this, not in their own Teutonic dialect, but in Latin. The use of Latin implies the use of Latin scribes or notaries, and implies that the laws were a notice to the Italians of the usages and rules of their conquerors, which, so far as they applied, were to be not merely the personal law of the Lombards, but the law of the land, and binding on Lombards and Romans alike. But such rule legislation could not provide for all questions arising even in the shattered and decayed state of Roman civilization. It is probable that among themselves the Italians kept to their old usages and legal precedents where they were not overridden by the conquerors' law, and by degrees a good many of the Roman civil arrangements made their way into the Lombard code, while all ecclesiastical ones, and they were a large class, were untouched by it.

The precise nature of the relations, legal and political, of the Lombards, as a conquering race, or a military caste, to the Italians is still a subject of controversy, owing to the prevailing mixture of clearness and obscurity in the documents of the time. There must have been, of course, much change of property; but appearances are conflicting as to the terms on which land generally was held by

the old possessors or the new comers, and as to the relative legal position of the two. Savigny held that, making allowance for the anomalies and usurpations of conquest, the Roman population held the bulk of the land as they had held it before, and were governed by an uninterrupted and acknowledged exercise of Roman law in their old municipal organization. Later inquirers, Leo, Troya, and more recently Hegel, have found that the supposition does not tally with a whole series of facts, which point to a Lombard territorial law ignoring completely any parallel Roman and personal law, to a great restriction of full civil rights among the Romans, analogous to the condition of the rayah under the Turks, and to a reduction of the Roman occupiers to a class of half-free "abdi," holding immovable property under lords of superior race and privilege, subject to the sacrifice either of the third part of their holdings or the third part of the produce. Probably something like this, with exceptions and anomalies, represents the state of things, at least at first; but it must be remembered that regular and consistent arrangements were very unlikely to have been thought of or made in a conquest as that of the Lombards, that the Romans suffered probably rather from the insolence of barbarians than from the rules of a constitutional settlement, and that a conqueror in such ways and naturally exaggerates its own hard conditions, especially in this case, as the chief teller of the story. It is to be expected that the tribal customs of Teutonic origin, which were modified in Italy, rather than elsewhere, by the traditions and customs of the old Roman rule. The Lombards and the Italians never ceased to be different; but we know by experience how two equal civil rights can hate one another, when the history of the Roman losses, and of the Lombard gains, is likely to be great at first; how far they could be reconciled during the two centuries of the Lombard kingdom. The legal distinctions between Rome and Lombard territory, is a further question. The Lombard kings, in form a territorial and not a personal law, assigned a disposition either to depose or to favour the Roman law, but on the purpose to maintain, in a rough fashion, strict discipline impartially among all their subjects.

From Rothari (*ob.* 652) to Liutprand (712-744) the Lombard kings, succeeding one another in the irregular fashion of the time, sometimes by descent, sometimes by election, sometimes by conspiracy and violence, strove fitfully to enlarge their boundaries, and contended with the aristocracy of dukes inherent in the original organization of the nation, an element which, though much weakened, always embarrassed the power of the crown, and checked the unity of the nation. Their old enemies the Franks on the west, and the Slavs or Huns, ever ready to break in on the north-east, and sometimes called in by mutinous and traitorous dukes of Friuli and Trent, were constant and serious dangers. By the popes, who represented Italian interests, they were always looked upon with dislike and jealousy, even when they had become zealous Catholics, the founders of churches and monasteries; with the Greek empire here was chronic war. From time to time they made raids into the unsubdued parts of Italy, and added a city or two to their dominions. But there was no sustained effort for the complete subjugation of Italy till Liutprand, the most powerful of the line. He tried it, and failed. He broke up the independence of the great southern duchies, Benevento and Spoleto. For a time, in the heat of the dispute about images, he won the pope to his side against the Greeks. For a time, but only for a time, he deprived the Greeks of Ravenna. Aistulf, his successor, carried on the same policy. He even threatened Rome itself, and claimed a capitation tax. But the popes, thoroughly irritated and alarmed, and hopeless of aid from the East, turned to the family which was rising into power among the Franks of the West, the mayors of the palace of Austrasia. Pope Gregory III. applied in vain to Charles Martel. But with his successors Pippin and Charles the popes were more successful. In return for the transfer by the pope of the Frank crown from the decayed line of Clovis to his own, Pippin crossed the Alps, defeated Aistulf, and gave to the pope the lands which Aistulf had torn from the empire, Ravenna and the Pentapolis (754-756). But the angry quarrels still went on between the popes and

the Lombards. The Lombards were still to the Italians a "foul and horrid" race. At length, invited by Pope Adrian I., Pippin's son Charles once more descended into Italy. As the Lombard kingdom began, so it ended, with a siege of Pavia. Desiderius, the last king, became Charles's prisoner (774), and the Lombard power perished. Charles, with the title of king of the Franks and Lombards, became master of Italy, and in 800 the pope, who had crowned Pippin king of the Franks, claimed to bestow the Roman empire, and crowned his greater son emperor of the Romans (800).

3. To Italy the overthrow of the Lombard kings was the loss of its last chance of independence and unity. To the Lombards the conquest was the destruction of their legal and social supremacy. Henceforth they were equally with the Italians the subjects of the Frank kings. The Carolingian kings expressly recognized the Roman law, and allowed all who would be counted Romans to "profess" it. But Latin influences were not strong enough to extinguish the Lombard name and destroy altogether the recollections and habits of the Lombard rule; Lombard law was still recognized, and survived in the schools of Pavia. Lombardy remained the name of the finest province of Italy, and indeed for a time was the name for Italy itself. But what was specially Lombard could not stand in the long run against the Italian atmosphere which surrounded it, with its countless and subtle forces, social, political, and religious. Generation after generation passed more and more into real Italians. Antipathies, indeed, survived, and men even in the 10th century called each other Roman or Langobard as terms of reproach. But the altered name of Lombard also denoted henceforth some of the proudest of Italians; and, though the Lombard speech had utterly perished, their most common names still kept up the remembrance that their fathers had come from beyond the Alps.

But the establishment of the Frank kingdom, and still more the re-establishment of the Christian empire as the source of law and jurisdiction in Christendom, had momentous influence on the history of the Italianized Lombards. The empire was the counterweight to the local tyrannies into which the local authorities established by the empire itself, the feudal powers, judicial and military, necessary for the purposes of government, invariably tended to degenerate. When they became intolerable, from the empire were sought the exemptions, privileges, immunities from that local authority, which, anomalous and anarchical as they were in theory, yet in fact were the foundations of all the liberties of the Middle Ages in the Swiss cantons, in the free towns of Germany and the Low Countries, in the Lombard cities of Italy. Italy was and ever has been a land of cities; and, ever since the downfall of Rome and the decay of the municipal system, the bishops of the cities had really been at the head of the peaceful and industrial part of their population, and were a natural refuge for the oppressed, and sometimes for the mutinous and the evil doers, from the military and civil power of the duke or count or judge, too often a rule of cruelty or fraud. Under the Carolingian empire, a vast system grew up in the North Italian cities of episcopal "immunities," by which a city with its surrounding district was removed, more or less completely, from the jurisdiction of the ordinary authority, military or civil, and placed under that of the bishop. These "immunities" led to the temporal sovereignty of the bishops; under it the spirit of liberty grew more readily than under the military chief. Municipal organization, never quite forgotten, naturally revived under new forms, and with its "consuls" at the head of the citizens, with its "arts" and "crafts" and "guilds," grew up secure under the shadow of the

church. In due time the city populations, free from the feudal yoke, and safe within the walls which in many instances the bishops had built for them, became impatient also of the bishop's government. The cities which the bishops had made thus independent of the dukes and counts next sought to be free from the bishops; in due time they too gained their charters of privilege and liberty. Left to take care of themselves, islands in a sea of turbulence, they grew in the sense of self-reliance and independence; they grew also to be aggressive, quarrelsome, and ambitious. Thus, by the 11th century, the Lombard cities had become "communes," commonalties, republics, managing their own affairs, and ready for attack or defence. Milan had recovered its greatness, ecclesiastically as well as politically; it scarcely bowed to Rome, and it aspired to the position of a sovereign city, mistress over its neighbours. At length, in the 12th century, the inevitable conflict came between the republicanism of the Lombard cities and the German feudalism which still claimed their allegiance in the name of the empire. Leagues and counter-leagues were formed; and a confederacy of cities, with Milan at its head, challenged the strength of Germany under one of its sternest emperors, Frederick Barbarossa. The struggle was terrible. At first Frederick was victorious; Milan, except its churches, was utterly destroyed; everything that marked municipal independence was abolished in the "rebel" cities; and they had to receive an imperial magistrate instead of their own (1158-62). But the Lombard league was again formed. Milan was rebuilt, with the help even of its jealous rivals, and at Legnano (1176) Frederick was utterly defeated. The Lombard cities had regained their independence; and at the peace of Constance (1183) Frederick found himself compelled to confirm it.

From the peace of Constance the history of the Lombards is merely part of the history of Italy. Their cities went through the ordinary fortunes of most Italian cities. They quarrelled and fought with one another. They took opposite sides in the great strife of the time between pope and emperor, and were Guelph and Ghibelline by old tradition, or as one or other faction prevailed in them. They swayed backwards and forwards between the power of the people and the power of the few; but democracy and oligarchy passed sooner or later into the hands of a master who veiled his lordship under various titles, and generally at last into the hands of a family. Then, in the larger political struggles and changes of Europe, they were incorporated into a kingdom, or principality, or duchy, carved out to suit the interest of a foreigner, or to make a heritage for the nephew of a pope. But in two ways especially the energetic race which grew out of the fusion of Langobards and Italians between the 9th and the 12th centuries has left the memory of itself. In England, at least, the enterprising traders and bankers who found their way to the West, from the 13th to the 16th centuries, though they certainly did not all come from Lombardy, bore the name of Lombards. In the next place, the Lombards, or the Italian builders whom they employed or followed, the "masters of Como," of whom so much is said in the early Lombard laws, introduced a manner of building, stately, solemn, and elastic, to which their name has been attached, and which gives character of its own to some of the most interesting churches in Italy. (R. W. C.)

LOMBOK (called Tanah Sasak by the natives, and Saliparan or Selaparang by the Balinese, Lombok being properly the name only of a village on the north-east side), an island of the East Indian Archipelago, belonging to the Lesser Sunda group, and separated from Bali by the Strait of Lombok, from Sumbawa by the Strait of Alas. It stretches from about 115° 44' to 116° 40' E. long. and from 8° 12' to 9° 1' S. lat., and its area is estimated at 2080 square miles. Rising out of the sea with bold and often precipitous coasts, Lombok is mountainous towards the south, and in the north-east contains one of the principal volcanic summits of the whole archipelago—Rindjant or Peak of Lombok, 8688 feet according to Hornburgh's measurement, 12,379 according to Melvill de Carnbee, and 11,834 according to Smits. There is no active crater in

the island, but in 1815 it suffered severely from the eruption of Tombora on the neighbouring island of Sumbawa. Of the numerous streams by which it is watered none are navigable except by small boats; among the mountain lakes Segara Anak, lying some 9000 feet above the sea, is noteworthy in point of size. The best harbour is Ampanan (8° 34' 15" S. lat., 116° 3' 40" E. long.) on the west coast, often visited by European and American vessels; that of Labuhan Tring farther south is also good, but less frequented. Forest-clad mountains and stretches of thorny jungle alternating with rich alluvial plains, cultivated like gardens under an ancient and elaborate system of irrigation, make the scenery of Lombok exceedingly attractive; and to the naturalist it is of particular interest as the frontier island of the Australian region, with its cockatoos and megapods or mound-builders, its peculiar bee-eaters and ground thrushes. Rice is the principal export; ponies, skins, ducks' eggs and other eggs, and edible nests, are also sent from the island. The rajah of Lombok (who has his capital at Mataram, a large village on the west coast, and his country seat at Gunong Sari) is tributary to the susuhunan of Bali and Lombok; he has possession of the whole island, which was formerly divided into the four states of Karang-Asam Lombok on the west side, Mataram in the north-west, Pagurawan in the south-west, and Pagutan in the east. Balinese supremacy dates from the conquest by Agong Dahuran in the beginning of the present century; the union under a single rajah dates from 1839. The population is variously estimated. The *Woordenboek van Ned. Ind.* (1869) gives about 405,000 souls; Behm and Wagner conjecture 100,000 in 1880. The greater proportion are Sassaks, as the Mohammedanized native stock are called; but the dominant Balinese, who still retain their Buddhist creed, may amount to about a twentieth of the whole.

LOMONÓSOFF, MIKHAIL VASILIEVICH (1711-1765), was born in the year 1711, in the village of Denisovka (which in later times has had its name changed in honour of the poet), situated on an island not far from Kholmogori, in the government of Archangel. His father, a fisherman, took the boy as soon as he was ten years of age to assist him in the labours of his calling; but his eagerness for knowledge was unbounded. The few books accessible to him he almost learned by heart; and, seeing that there was no chance of his stock of knowledge being enlarged under the arctic skies of his native place, he resolved to betake himself to Moscow in the best way he could. An opportunity occurred when he was seventeen years of age, and by the intervention of friends he obtained admission into the Zaikonospasski school. There his progress was very rapid, especially in Latin, and in 1734 he was sent from Moscow together with other promising students to St Petersburg. There again his proficiency, especially in physical science, was remarked by all, and he was one of the young Russians chosen to complete their education in foreign countries. He accordingly commenced the study of metallurgy at Marburg; but, not content with his work under the professors, he now began to write poetry, imitating German authors, among whom he is said to have especially admired Günther. His *Ode on the Taking of Khotin from the Turks* was composed in 1739, and attracted a great deal of attention at St Petersburg. During his residence in Germany Lomonósoff married a native of the country, and found it difficult to maintain his increasing family on the scanty allowance granted to him by the St Petersburg Academy, which, moreover, was

irregularly sent. His circumstances became embarrassed, and he resolved to leave the country secretly, and to return home. On his arrival in Russia, after an adventure with a Prussian recruiting officer which at one time threatened serious consequences, he rapidly rose to distinction, and was made professor of chemistry in the university of St Petersburg; he ultimately became rector, and in 1764 secretary of state. He died in 1765.

The most valuable of the works of Lomonósoff are those relating to physical science, and he wrote upon many branches of it. He everywhere shows himself a man of the most varied learning. He compiled a Russian grammar, which long enjoyed popularity, and did much to improve the rhythm of Russian verse. Many of his poems are good, but they do not constitute his chief claim to be remembered. The school upon which he formed himself as a poet was a bad one. We must remember that these were the days of falsely-conceived classicism, and the French taste upon which all the literature of Europe was moulded. His great merit is that he belongs to the glorious band of patriots, which includes such men among Slavs as Dositei Obradovich, Raich, and Prumir Trubar, — men whose object was to elevate and give dignity to their country, earnest toilers in the field of national education.

LOMZA, or LOMZHA, a government of Russian Poland, is bounded on the N. by Prussia and the Polish government of Suwalki, on the E. by the Russian government of Grodno, on the S. by the Polish governments of Siedlee and Warsaw, and on the W. by that of Plock. It covers an area of 4670 square miles, or 9½ per cent. of all Poland. It is mostly flat or undulating, with a few tracts in the north and south-west, where the deeply-cut valleys give a hilly aspect to the country. Extensive marshes overspread it, especially on the banks of the Nareff, and in the east there are also good forests. Lomza is traversed by the Nareff, which flows from east to south-west, joining the Bóg in the south-western corner of the government. The Bóg flows along the southern border, joining the Vistula 20 miles below its junction with the Nareff. The inhabitants numbered 501,385 in 1872, the Poles constituting 76 per cent. of the population (or 83 per cent. when the Poles who are mixed with Lithuanians are included), the Jews 14½ per cent., and the Germans 2 per cent. Of this population 402,146 belonged in 1870 to the Catholic Church, 10,354 to the Protestant, and 1817 to the Greek and United Churches. In 1878 394,570 were peasants, while only 76,950 belonged to the citizen class, and 11,470 to the nobility (*szlachta*). In 1877 45 per cent. of the total area, or 1,366,000 acres, were under crops. Stock raising is carried on to some extent (197,900 cattle, 263,700 sheep, and 68,705 horses). The wood trade is an important branch of industry, but manufactures are very imperfectly developed, the total production in 1873 having been only some £110,000, or 1·3 per cent. of the total for Poland. Lomza produces some wooden wares, spirits, tobacco, and sugar. There is only one railway (between Grodno and Warsaw); the Bóg is navigable, but only wood is floated down the Nareff. The province is divided into eight districts, of which the chief towns are Lomza (13,860), Pultusk (7950), and Ostrolenka (6900) on the Nareff; Mazowiec (2750), Ostrow (6300), Maków (6600), Kolno (4800), and Szczuczyn (4750). Tykocin (5400) and Nasielsk (6250), although not district towns, have lately acquired some importance.

LOMZA, capital of the above province, on the Nareff, 80 miles north-east from Warsaw, and 30 miles north from the Chizheff station of the railway between Warsaw and Grodno, had a population in 1872 of 13,860.

Lomza is an old town, one of its churches having been erected before the year 1000. In the 16th century it carried on a brisk trade with Lithuania and Prussia. It was well fortified and had two citadels, but nevertheless had often to suffer from the invasions of Germans and Tartars, and in the 17th century it was twice plundered by the Cossacks of the Ukraine. In 1795 it fell under the dominion of Prussia, and after the peace of Tilsit it came under Russian rule.

IX., X.

**L**ONDON, the metropolis of England, and the chief town of the British empire, is situated on both banks of the river Thames, about 50 miles from its mouth, St Paul's Cathedral being in  $51^{\circ} 30' 48''$  N. lat. and  $0^{\circ} 5' 18''$  W. long. The old City of London is wholly included in the county of Middlesex, but the town beyond the City limits extends into portions of three other counties,—namely, Surrey and Kent on the south, and Essex on the east. The area and population of the various governmental divisions of London are given below (pp. 821, 822).

Geology.

**SITE.**—A great part of London is built on sands and gravels belonging to the Drift period, marking the ancient bed of a much larger river than the present Thames. This formation, resting immediately on the London Clay, extends along both banks of the present river, with an average breadth of about 2 miles; but in some parts there is immediately adjoining the banks a considerable breadth of alluvial deposits, or occasionally of artificially constructed embankments. On the north bank the alluvial soil comprehends the greater part of Westminster; on the south bank it stretches east from Lambeth Bridge, gradually widening to a breadth of about half a mile, and from Southwark to Deptford occupying a still wider area. The sands and gravels again occur at Greenwich Hospital, but are succeeded by the Greenwich and Woolwich marshes. The Isle of Dogs opposite Greenwich is constructed wholly of artificial embankments, and at one time the area it now occupies formed part of the mouth of the Lea, along whose banks the alluvial formation runs northwards between Bow and Stratford to Stoke Newington, widening to a considerable area at the marshes of West Ham and Plaistow. At Fencham, Battersea Park, Cheapside, Victoria Park, and to the south of Stoke Newington, there are considerable areas occupied by brick earth. The London Clay crops to the surface throughout the whole of north-west London, with the exception of a small portion to the south of Regent's Park, which is encroached upon by the sands and gravels, and the summits of Hampstead and Highgate, which are occupied by the silicious sands of the Bigshot series. In west London the Clay extends south to Kensington Gardens, and in north London it occupies part of Islington and the district north of Highbury and Stoke Newington. South of the Thames it encroaches irregularly on Wandsworth, Clapham, Camberwell, and Deptford, and comprehends nearly all the district round Sydenham. The Lower Tertiaries are represented by the Thanet sands at Greenwich and in the neighbourhood of Deptford, by the Woolwich and Reading beds, which occur at Camberwell, Dulwich, and Lewisham, and by the Blackheath beds, which are best seen at Blackheath. Chalk, the basement rock of the London basin, and the source of the water supply for the deep wells, only crops to the surface in the neighbourhood of Greenwich.

Surface.

The original surface of the soil of London has been much altered in the course of generations, the depth of made earth being often very great. At one period the Thames flowed straight from Lambeth to Limehouse, and the greater part of the district now stretching south and east of the river to the range of heights in the neighbourhood of Sydenham and Greenwich was occupied by marshes or shallow lagoons. North of the Thames the greater part of London is built on several ranges of small eminences lying between the river and the northern heights of Hampstead (139 feet), Highgate, and Hornsey. The original city clustered round the eminence now crowned by St Paul's, and formerly intersected by the ravine of the Walbrook.

To the north and east it was bounded by an extensive fen, from which Finsbury takes its name. To the west was the Fleet river, which flowed from Hampstead in a southeasterly direction to King's Cross, and then more southerly to Clerkenwell, where on account of the steepness of its banks it received the name of Holebourne, or Hollowburn. It was navigable to King's Cross, and for a long period formed a convenient and well-protected harbour for the city. A more extended elevation, included in the district now occupied by the Inns of Court, Bloomsbury, and Soho, was bounded on the west by the Tyburn, which rose near the Swiss Cottage and, after an easterly course till reaching the present Regent's Park, flowed southwards nearly in the line of Marylebone Lane and Bond Street. Tyburn Hill was bounded on the west by the Westbourne; and to the south and west an extensive range of low ground, now included in Westminster, Pimlico, Chelsea, and Kensington, was in early times for the most part covered by water. Westwards the low ground is bounded by Notting Hill, whence an elevated region lying between the smaller eminences and the "northern heights," and including Primrose Hill, runs in a north-westerly direction to Camden Town, Islington, and Highbury. The hilly regions in the neighbourhood of Kensington and Notting Hill formed part of an extensive forest, and St John's Wood was originally a dense thicket.

**GOVERNMENT AND ADMINISTRATION.**—At first the Administrative history. municipal constitution of London was loose and disjointed in its form, resembling that of the shire rather than the town, but even from the time of Henry I. the independence of its jurisdiction was complete, and the citizens, besides the right of inheritance and tenure not then possessed by the rest of England, enjoyed exemption from the Danegeld and from similar obligations. By the 13th century the later form of the municipality was already shaped in its main features, although at this stage residence in the borough and not membership in a trade guild was the basis of citizenship. This in some respects premature development of municipal functions has always given to London a peculiar and unique position in respect of municipal government. Its charters, which in early times served as the model for charters to new incorporations, have defied the attacks of reform. The system of government was more heterogeneous and complicated than that of other English towns. London is practically a borough by prescription, and its special rights and privileges have made those who possess them distrustful of change. The mere extent of the new city surrounding the old, and the rapidity of its growth, have also tended to postpone the attempt to grapple with the problem of its government. Until 1855, when the Metropolitan Board of Works was formed, the whole administration of the metropolis was of a mediæval character. The City was governed by old charters, confirmed but not interpreted by a special Act of William and Mary, and the various parishes of the rest of the metropolis had each its own peculiar system of administration, regulated by local Acts which differed widely in different localities. No direct change of vital importance was made in the constitution and functions of the City corporation by the Metropolitan Local Management Act of 1855, but the very existence of the Metropolitan Board implied a certain limitation of its authority, and the additional functions conferred by successive Acts on the Metropolitan Board have in some degree circumscribed its influence. As modified by the Act of 1855, the government of London within what is known as the metropolitan area consists of the City Corporation, the Metropolitan Board of Works, and thirty-eight

vestries and district boards; while various authorities, to be afterwards mentioned, exercise jurisdiction in special matters over the whole area of the metropolis or in separate localities.

Government of the City.

The City of London, which is a county in itself, and with which the borough of Southwark is assimilated, is governed by a lord mayor, twenty-six aldermen, and two hundred and six common councillors, forming a Court of Common Council. This court has a certain independent power to enact regulations for the government of the City, is entrusted with the management of the finances and the estates of the corporation, elects most of the officials, and controls the police. The City elects a sheriff of Middlesex as well as a sheriff of London; and the lord mayor is elected by the trade guilds in common hall from among the aldermen who have served as sheriffs. He is lord lieutenant within the City, the dispenser of its hospitality, the chairman of the courts of the corporation, and holds certain other offices, the dignity of which is now almost entirely nominal. The aldermen, who hold office for life, are chosen by the several wards, each ward electing one. Since 1867 the power of election has been enjoyed by all possessing the household and lodger franchise. The Court of Aldermen has the power of appointment to certain offices, exercises judicial functions in regard to licensing and in disputes connected with the ward elections, has some power of disposal over the City cash, and possesses magisterial control over the City, each alderman being a judge and magistrate for the whole City, and by virtue of his office exercising the functions of a justice of the peace. The common councillors were chosen originally in the reign of Edward I. as assistants to the aldermen, and in 1381 were constituted a standing committee to regulate the affairs of the City, each ward choosing four, six, or eight, according to its size. A gradual increase in their number took place until 1840; when it was fixed at two hundred and six. From the time of Richard II. the election was vested in freemen householders, but it is now regulated by the Act of 1867. The Court of Common Hall, formerly the popular assembly or ancient *folk-mote*, is now composed of the lord mayor, four aldermen, and the liverymen of the city guilds, and nominates yearly two aldermen, who must previously have been sheriffs, for the Court of Aldermen to select one for the office of lord mayor. The sheriffs are themselves chosen by the Court of Common Hall, which also appoints the chamberlain, the bridge masters, and the city auditors.

City guilds.

The fragmentary and indirect participation in the government of London at present exercised by the livery companies represents the remnants of an influence which was paramount from the time of Edward III., when enactments were passed which made admission to the freedom of the city dependent on membership in a trade or mystery. Originally established to afford mutual aid to members of their "craft," the guilds of London gradually assumed a certain control over their trade or manufacture, and by the payment of large sums of money obtained various monopolies, with the power to make by-laws for the regulation of their craft. From gifts for charitable purposes, and from entrance-money and fines, many of the guilds, on account of the rise in the value of property, have amassed enormous wealth. Within the limits of the City alone the gross annual rental of the land possessed by them is over £500,000, and it is believed that the land they possess outside its limits is of equal value. At one time their number was over one hundred, but they now number seventy-six, and some represent trades which are extinct. Twelve so-called "great companies" claim precedence over the others, but of these some are not so wealthy as a few of the less highly privileged. The "livery" or dress of the companies, first formally adopted

in the reign of Edward III., was ultimately worn only by a higher grade of the members called liverymen. The extension of London beyond the City limits and changes in trade maxims and in social life have now left them little more than the shadow of their former authority over trade and manufacture, but a few, such as the fishmongers, the stationers, the goldsmiths, and the apothecaries, still discharge certain functions in the regulation of their several crafts. Besides administering their charities, many of the companies contribute largely to benevolent objects of pressing need, and some take an interest in promoting technical instruction, and in various matters relating to their special trade or manufacture; but the business of most of them is now chiefly of a ceremonial kind. The halls of the companies number thirty-five, and many of them are of interest either from their architectural merits, their antiquarian associations, or the portraits or other objects they contain. Their annual assessed value is over £60,000. The hereditary connexion of the companies with the corporation, their large ownership of property in the City, and their control over so many charities still enable them to exercise a very great influence in municipal affairs.

The following list (Table I.) gives details regarding the twelve great companies, and six other companies which may be ranked next to them in importance:—

Name.	Date.	Situation of Hall.	Purchase of Hall.	Assessed Value.
<i>Great Companies.</i>				
Mercers .....	1393	Chancery Lane .....	£ 11 0	23 10

The corporation of the City of London still retains special certain exceptional prerogatives. The lord mayor's court still exercises civil jurisdiction, the two courts of the sheriffs' compters survive in the City of London court, and the lord mayor exercises the functions of judge in the central criminal court, which superseded the court of oyer and terminer in 1831, and extends beyond the radius of the Metropolitan area. The corporation possesses the sole right to establish markets within 7 miles of the City: it enjoys a metage of grain, partially commuted in 1872 to a fixed duty chargeable by weight, and applied to the preservation of Epping Forest and other open spaces; and it levies coal and wine duties, continued by various Acts, for defrayment of the cost of public improvements. Most of the work of the corporation is performed by committees; and "commissioners of sewers," under Act of Parliament, have charge of the cleaning, lighting, and paving of the streets.

A large portion of the City income is derived from rents, which increased from £3488 in 1692 to £19,199 in 1785, £45,260 in 1825, and £117,781 in 1881. In 1692 the City market was farmed for £3100, the profit being about £2500; in 1785 the revenue was £15,631, and the profit £2621; in 1825 these were respectively £58,958 and £52,271; and in 1881 they were £152,810 and £20,911. The total revenue of the City in 1692 was £11,658 in 1785 £59,556, and in 1881 £89,688, not including the public and trust accounts, which are regulated by various Acts of Parliament. They include the Bridge-House estate account, the sewers rate, the Metropolitan Board of Works sewers rate, the police rate, the ward rate, and the duties on coal, wine, and grain. The total charge of the government establishment in 1692 was £3947, and in 1881 it was £51,855, not including £7866 spent in pensions of

officials. In 1692 the lord mayor received an annual sum of £100 for his care of the market, and an ancient fee of £80 out of the chamber. He has now an annual salary of £10,000, and in addition to this his personal expenses in 1881 amounted to £4433. The salaries of the recorder, the chamberlain, the common sergeant, the town-clerk, and some other officers have risen in a somewhat similar proportion. The City in 1692 spent nothing on special acts of hospitality or on the promotion of literature, science, or art, while its contribution to the poor rates was only £66. It now spends several thousands annually on the reception of eminent persons, while to the London almshouses it in 1881 contributed £1884, to general charitable purposes £5179, for education £5394, for technical instruction £2000, for the Guildhall library and museum £5398, and for music £3027. The debt of the corporation, which is solely connected with the construction of improvements and public markets, was on December 31, 1881, £5,496,150, the money spent for these purposes since 1759 being nearly £10,000,000. The rateable value of the City and liberties has since 1801 increased sevenfold, having risen from £507,372 to £3,535,494.

**Corporation.** The Guildhall, rebuilt by Dance in 1789, contains the greater part of the walls of the old building of 1411, which was damaged by the fire of 1666, and also the crypt divided into three aisles by clustered columns of marble supporting a groined roof richly adorned with carvings. The principal front was restored in 1867 in the Gothic style. In addition to the great hall used for state banquets and receptions, the building contains the common council chamber, the aldermen's room, and several courts of justice. Adjoining the Guildhall is the free library of the corporation, and a museum of antiquities relating to the City. The Mansion House at the east end of the Poultry, erected in 1710 from the designs of Dance, is the official residence of the lord mayor. In addition to the justice room and various reception rooms, it contains the Egyptian hall, in which certain special banquets of the lord mayor are held.

**Metropolitan Board.** By the Metropolis Local Management Act of 1855, the metropolis was divided into thirty-nine vestries or district boards, which elect the forty-five members who form the Metropolitan Board of Works, the city of London electing three members, each of the six great parishes of Islington, Marylebone, St Pancras, Lambeth, St George's (Hanover Square), and Shoreditch two members, and the other districts one each or one in combination. The board was originally established for the formation and maintenance of main sewers, but later Acts have made it the administrative authority of the metropolis in a great variety of other matters, including the construction of main thoroughfares, the carrying out of great metropolitan improvements, the formation of new streets, the construction and maintenance of parks, the preservation of commons and open spaces, the maintenance of the fire brigade, and the administration of certain enactments specially applicable to the metropolitan area. The total sum raised by the board for application to its various purposes since 1856 to 31st December 1881 was £28,689,749, and its net liability on the 31st December 1881 was £13,437,940. The capital required for the execution of great works is raised by the issue of stock bearing interest at the rate of 3½ and 3 per cent., which has the same facilities of transfer as the Government stocks, and is redeemable in sixty years from creation. The rate per pound levied by the board has varied very greatly, being 2·09d. in 1856, and as high as 6·99d. in 1867, while for 1883 it is estimated at 6·2d. The total net charge in 1880 was £652,213, and for 1882 it is estimated at £715,822. The rateable annual value of property in the metropolis has risen from £11,283,663 in 1856 to £27,386,086 in 1882.

**Vestries.** The vestries and district boards are entrusted with the management of local sewers, the lighting, paving, and cleaning of their own thoroughfares, and the removal of nuisances. For paving, except in the old main thoroughfares, they have power to charge adjoining properties, and in several districts a small income is obtained from

realized property. The total amount of money advanced to them on loan by the Board of Works up to 31st November 1881 was £3,631,769, of which £3,297,430 was redeemable by 1929, and £334,338 by 1941.

The School Board of London has in regard to education a rating and legislative authority over a district corresponding with that of the Metropolitan Board of Works. The metropolitan police force outside the City limits and within a radius of 12 miles of Charing Cross is under the control of the Home Secretary. The Tower of London is governed by the constable of the Tower, assisted by fifty magistrates, and the borough of Westminster is still under the nominal care of the dean and burgesses. The Metropolitan Asylums Board, the Burial Board, the Thames Conservancy Board, and the Lea Conservancy Board constitute the principal other direct governing authorities having relation to London, but the water and gas companies enjoy monopolies which imply a certain degree of irresponsible authority, and a right of taxation not sufficiently defined and limited. Within an area less than the district of the Board of Works there are ten parliamentary boroughs, which return in all twenty-two members, the City returning four members, and Southwark (from 1295), Westminster (1547), Marylebone (1832), Finsbury (1832), Tower Hamlets (1832), Greenwich (1832, extended in 1868), Lambeth (1832), Hackney (1868), and Chelsea (1868) two each. London University (1868) returns one member.

**GROWTH AND POPULATION.**—For some centuries after the Conquest there are almost no data for an estimate of the extent and population of London, but a great impulse was given to its increase by the settlement of Normans and the opening up of intercourse with the Continent. The statement of Fitzstephen that it furnished, in the reign of Stephen, 60,000 men-at-arms and 20,000 knights cannot be accepted as applying only to the City. Peter of Blois, under Henry II., only estimated its numbers at 40,000, although he may possibly have referred only to adults (*Opera*, ed. Giles, vol. ii. p. 85). In any case, previous to the great plague of 1349 it must have numbered at least 90,000, for in that year, according to Stow, as many as 50,000 persons were buried in the cemetery of Spitalcroft, specially consecrated for the purpose. There were severe ravages from the same cause in 1361 and 1369; and the calculation of Chalmers (*Comparative Estimate of Great Britain*, 1802), founded on the Subsidy Rolls of 1377, shows a population of only 34,971; but the emperor Manuel II., who visited it in 1400, states that it was to be preferred to every city of the West for population, opulence, and luxury (Macpherson, *Annals of Commerce*, vol. i. p. 611). Notwithstanding the regulations of Elizabeth for checking its growth, London had by the end of the century advanced considerably beyond its old boundaries. Giovanni Botero, writing about 1590, classes it with Naples, Lisbon, Prague, and Ghent as possessing about 160,000 inhabitants more or less, while Paris was said to possess over 400,000 inhabitants. The "Bills of Mortality" which were begun in 1592, were in 1604 extended to St Bartholomew the Great, Bridewell Precinct, and Trinity in the Minories, which were partly within the City liberties, and to St Clements Danes, St Giles-in-the-Fields, St James (Clerkenwell), St Catherine (Tower), St Leonard (Shoreditch), St Mary in Whitechapel, St Martin-in-the-Fields, and St Mary Magdalen (Bermondsey). St Mary at the Savoy was added in 1606, and Westminster in 1626. The parishes of Hackney, Islington, Lambeth, Newington, Rotherhithe, and Stepney, which were included in 1636, were, according to Graunt (*Observations on the Bills of Mortality*, 1676), still country villages in 1672, and indeed occupied an isolated position up to the middle of the 18th century. The result of the census of the

city taken in 1631 is given by Graunt as 130,178, but the sum of his details is 130,268. By 1661 he reckoned it to have increased to 179,000. He also concluded that the population within the limits of the "Bills of Mortality" was 460,000, and that from the beginning of the century it had increased from 2 to 5. The population of London and its suburbs, excluding Westminster and the distant parishes, he placed at 384,000, or about a fourth less than Paris. Notwithstanding the plague of 1665 and the fire of 1666, London towards the close of the 17th century increased with great rapidity. Evelyn, writing in 1684, states that it had nearly doubled within his own recollection. Sir William Petty, in his *Essay on Political Arithmetic*, estimated the population in 1683, including that of Westminster and Southwark, at 696,000, but Gregory King, in his *Observations on the State of England*, first published by Chalmers, allowing  $5\frac{1}{2}$  persons to every house, makes it in 1694, within the limits of the "Bills of Mortality," only 530,000. From about this period London superseded Paris as the largest city in Europe. During the first half of the 18th century its progress was fluctuating, but on the peace of 1763 a great impulse was given to its prosperity, and after 1780 a rapid rate of progress commenced, which still shows no signs of diminution. Until 1756 there was sufficient space for the Mayfair east of Hyde Park, but by the end of the century the aristocracy had nearly all migrated west from Covent Garden and Soho. Islington was still almost disjointed from the metropolis, but the great eastern suburbs had become so consolidated as almost to absorb even Hoxton, Bethnal Green, and Stepney. The first census of 1801 included St Pancras, Marylebone, Paddington, Kensington, and Chelsea, but Chelsea was still a solitary suburban retreat, Kensington was little more than "the old court suburb," Paddington and Westbourne were rural hamlets, and Marylebone and St Pancras had less than one-fourth of their present population. The populous city surrounding Regent's Park had scarcely any existence before 1820, but by 1830 it as well as Somers Town had become absorbed in the metropolis, especially by additions in the neighbourhood of St Pancras church and London university. Eastwards the most rapid extension had been in the direction of Greenwich, which was now united with Lambeth by a continuous line of houses. Bolgravia in the south-west, and Tyburnia to the north of Hyde Park are chiefly the product of the next twenty years. Since that period the suburban districts have in all directions become almost consolidated, and beyond the present limits

of the registrar-general fringes of houses not proved of some instances outside even the 12 mi Charing Cross, connect the metropolis over the London towns which a few years ago were so given in the July Within the last twenty years the rate of increase in the outer ring of this greater London has been 100 per cent., while that of London proper has been 63·8 per cent. its outer ring showing an increase of 63·8 per cent. that the its central area a decrease of 13·2,—the decrease that over City being 54·8, in the Strand 30·5, St Giles 100·9 to Holborn 9·5, Westminster 11·9, St George's (Hanover Square) and Marylebone 4·1, and in the eastern central districts of Whitechapel, St George-in-the-East, and Shoreditch 9·6, 3·8, and 2·2 respectively. In these latter districts the decrease has been occasioned chiefly by improvements, but in the central business districts it is almost entirely the result of the substitution of business premises for dwelling-houses. The day census of the City taken in 1866 shows that the number of persons employed daily within its limits was 170,133, and that of 1881 gives a day population of 261,061, while the night population in 1871 was 74,897 and in 1881 only 50,526. The rapidity of the growth of London is largely due to the peculiar development of its trade and commerce, and is also closely connected with the interest excited by politics and the meetings of parliament. The bonds of connexion between London and England thus pulsate daily with a manifold vitality. London is the emporium of England, the centre of its great monetary transactions, the home of its science, literature, and art, and the yearly resort of its aristocratic and landed proprietor classes. Since the beginning of the century its rate of increase has exceeded that of England generally.

The proportion of inhabitants born outside its limits amounts to one-third of its entire population. The number of the natives of European states is in excess of those born in Scotland, and that of the natives of Ireland is about double, while the natives of the counties of England and Wales amount to more than a million. Irishmen by descent may be estimated at about 250,000 persons, Scots 120,000, foreigners 200,000, viz., Asiatics, Africans, and Americans together 45,000, Europeans 155,000 (Germans 60,000, French 30,000, Dutch 15,000, Poles 12,000, Italians 7500, Swiss 5000). The number of Jews is about 40,000. The special foreign district of London is that of Soho; another foreign district lies in the neighbourhood of Ratcliff Highway, now St George Street. The lower-class Jews inhabit the neighbourhood of Houndsditch and Aldgate. The Italian street musicians and vendors of ices form a small colony near Hatton Garden.

Table II. shows the percentage of the population of London to Tables of the rest of England, the numbers before 1801 being only approximate; Table III. the areas, houses, and population of London in tion.

ntal divisions; and Table IV. the population officials. In 1692 the four districts at different periods from 1801.

for his care of the metropolis, &c.—By the non-adoption of Wren's chaucer. He has no opportunity afforded through the great fire was to this his personal opportunity afforded through the great fire was salaries of the 1690 of constructing a model capital, and within town-clerk, and sets the streets are still in many cases confused proportion. The total absence of plan in the construction of the nucleus of London has doubtless tended to several the confusion outside the old boundaries. The while to the of the immense new outer city was, moreover, for general of the streets totally unregulated by the control of any central authority. The principal lines of streets formed along the communication for the increased population, and the absence of direct connexion between important points causes traffic to be enormously impeded. The longest line of street communication in London is that which is formed by the junction of the lines of the Edgware and Uxbridge Roads at the Marble Arch, whence it extends eastward by Oxford Street, Holborn, Newgate Street, Cheapside and other important City streets, Whitechapel Road, and Mile End Road to Bow. At Cheapside a branch from it runs westward by Fleet Street, the Strand, Haymarket, Piccadilly, and Knightsbridge to Kensington. Much of the effect of the fine architecture of the City streets is totally lost from promiscuous crowding, and the main connecting streets between the City and the West End display, at certain parts, much meanness and incongruity. Regent Street, the most fashionable thoroughfare of London, possesses ample width, and the splendour of its shops to some extent atones for the plain monotony of its regular architecture. In Oxford Street, which ranks next to it in importance, many buildings of a more ornamental character have lately been erected. Piccadilly, the eastern half of which is occupied chiefly by shops, and the western by dwelling houses and clubs, is a medley of every species of architecture, but is to some extent effective from the variety of its contrasts, and its outlook to the Green Park.

Trafalgar Square, with its fountains, its Nelson column, its statues, and its wide expanse, has an airy and pleasant effect, but the huge erections which surround it are a very miscellaneous group, and few of them are worthy of the site. The clubs and hotels in Pall Mall and its neighbourhood represent every variety of Grecian and Italian architecture. The private houses in the more fashionable regions are not remarkable for external beauty, but in summer time flowers and foliage give the West End squares and terraces a bright and pleasant aspect. A special characteristic of London is the enormous space covered by the suburban cottages and villas of the middle classes. Close to the most fashionable regions there are many mean back streets tenanted by workmen, but the principal territories of the working classes are comprehended in the dense and dreary districts east and south-east of the City. The improvements lately carried out in the City and other central districts, and the substitution of business premises for dwelling houses, have compelled large numbers of these classes to live at a long distance from their work, and also caused undue crowding in the less remote regions. The running of workmen's trains from the suburbs and the efforts of various private building associations and of the Metropolitan Board, guided by the Artisan and Labourers' Dwellings Improvement Act, have only partially mitigated these evils.

Since 1785 the greater part of London within the City Street limits has been rebuilt, and its streets have been much improved, altered, the principal improvements being the reconstruction of the lines from London Bridge to Finsbury Pavement, and from Blackfriars Bridge to Farringdon Road, both intersecting the City from north to south; the rebuilding of Bartholomew Lane, Lothbury, Threadneedle Street, and Cannon Street from King William Street to St Paul's; and the construction, in conjunction with the Metropolitan Board, of the Holborn Viaduct and of Queen Victoria Street from Blackfriars Bridge to the Mansion House. The Metropolitan Board now exercises a certain

control over the formation of new streets, but its powers are hampered by previous circumstances and by various restrictions. The principal new thoroughfares opened up by the board, besides Queen Victoria Street and the Holborn Viaduct, are Garrick Street, Covent Garden (1861), Southwark Street (1864), Northumberland Avenue (1876), and Theobald's Road and Clerkenwell Road, begun in 1873 to connect Oxford Street and Old Street. They have also effected extensive improvements in the neighbourhood of Whitechapel, Shoreditch, Park Lane, and Kensington. The more important schemes in contemplation are a new street from Tottenham Court Road to Charing Cross, another from Oxford Street to Piccadilly Circus, the widening of Coventry Street, of Gray's Inn Road, and of Tooley Street, and alterations of a less extensive character at Kentish Town, Hackney, and Camberwell. A scheme has been put forth by Government to relieve the pressure at Hyde Park Corner. Altogether up to 31st December 1881 the board have expended in street improvements £6,531,856, of which probably one-third will be defrayed by sales of property. In addition to this over £4,000,000 have been spent on the Thames Embankment and Queen Victoria Street, and the board have contributed about £626,077 to defray local improvements by district boards and vestries, as well as £1,360,500 for artisans' dwellings.

**Thames Embankment.** The Thames Embankment, with its marine wall of large granite blocks facing the river, supports on the north side a spacious thoroughfare which forms one of the finest promenades in London. The total cost of the various portions of the embankment was over £3,000,000, the greater part of which is being defrayed by the coal and wine duties levied by the City corporation. By the construction (1864-70) of that portion known as the Victoria Embankment, stretching from Blackfriars Bridge to Westminster, about 37 acres of land have been reclaimed, of which 19 are occupied by carriage and footways,  $7\frac{1}{2}$  have been conveyed to adjoining proprietors, and about 8 have been formed into ornamental grounds. The Albert Embankment (1865-68), stretching on the south side of the river from Westminster Bridge to Vauxhall Bridge, includes about 9 acres, which are now chiefly occupied by St Thomas's Hospital. The Chelsea Embankment (1871-74), which is the extension of one previously constructed between Vauxhall Bridge and Chelsea Hospital, involved the reclamation of about  $9\frac{1}{2}$  acres of ground, now occupied partly by a roadway 70 feet wide, and partly by a flower garden.

**Bridges.** There are twelve bridges, other than railway bridges, over the Thames within the metropolitan area, the most easterly being London Bridge and the most westerly Hammersmith Bridge. Three of these, London Bridge, Southwark Bridge, and Blackfriars Bridge, are within the City area. New London Bridge, a noble structure by Rennie, was opened in 1831, having cost £1,458,311. As populous and busy commercial districts extend for several miles to the east of it on both sides of the Thames, it is not only totally inadequate for the requirements of traffic, but is also removed beyond many convenient lines of communication. On this latter account the proposal to widen it—in itself a very unsatisfactory plan—has met with almost no support; but a bill promoted by the Metropolitan Board for erecting a high level bridge at the Tower failed also to commend itself to a committee of the House of Commons. Until 1769, when the Blackfriars Bridge was erected, London Bridge stood alone. Old Blackfriars Bridge was replaced in 1869 by the present one of five iron arches resting on granite, erected from the designs of Peto at a cost of £320,000. Southwark Bridge, designed by Rennie, 1815-19, consists of three iron arches of great elegance resting on stone piers, and cost £800,000. Partly from

the unsuitability of its approaches, it has not proved of very much service.

The number of passengers and vehicles passing over the London and Blackfriars Bridges in a single day of 1823 is given in the July number of the *Monthly Review* for that year, and in 1881 similar information was obtained, in regard to the three bridges, for the traffic in the direction of the City. Multiplying these figures by two, we find that the foot passengers crossing London Bridge in 1823 numbered 89,640, while in 1881 they were 157,886, and that the number of vehicles had increased from 6182 to 21,166; that over Blackfriars Bridge the passengers had increased from 67,069 to 87,131, and the vehicles from 1017 to 14,584, while 20,090 passengers and 3560 vehicles passed over Southwark Bridge, the increase in the number of passengers over the three bridges being thus 124,401, and of vehicles 28,381. At the earlier date Southwark Bridge was practically unused, but in 1865 the toll was abolished, and the bridge purchased by the corporation for £218,808. The Metropolitan Toll Bridges Act of 1877 required the Metropolitan Board to extinguish the tolls on all the Thames bridges and the bridge over Deptford Creek, and thereafter to repair and maintain them, the county authorities of Middlesex and Surrey paying each £1200 a year towards their maintenance. The bridges freed by the Act were the Charing Cross foot-bridge, for which £98,540 was paid to the South-Eastern Railway; Waterloo Bridge (1811-17) designed by Rennie in a style similar to London Bridge, constructed at a cost of £1,000,000, and purchased for £475,000; Lambeth Bridge (1862), built of iron at a cost of £10,000, and purchased for £36,049; Vauxhall Bridge (1811-16), similar in form to Southwark Bridge, erected for over £300,000, and purchased for £225,230; Chelsea Suspension Bridge (1858), designed by Peto, erected by the Government for £88,000, purchased for £75,000; the Albert Suspension Bridge (1873) and Battersea Bridge, an old wooden structure, both purchased for £300,000; Wandsworth Bridge for £52,761; Putney Bridge (1729), a picturesque old timber structure, for £58,000; and Hammersmith Bridge for £112,500. Battersea and Putney bridges are about to be re-erected, and Deptford Creek Bridge is to be widened and improved at a cost of £109,091. The total amount of money spent by the board in connexion with bridge up to 18th December 1881 was £1,479,097. The amount to be paid by the board for their maintenance in 1882 is estimated at £90,502. The river is crossed by many railway bridges, and the Thames tunnel, begun in 1825 and completed in 1843, at a cost of £168,000, for the purposes of traffic, was purchased in 1865 by the Great Eastern Company, and is now used as a railway tunnel. A subway under the Thames from Tower Hill to Tooley Street was constructed in 1869 at a cost of £16,000. The communication in the neighbourhood of the river is greatly facilitated by the frequent passenger steamers.

The cleaning, watering, and paving of the streets are more satisfactory than might be expected from the fact that each district tenancy depends solely on its own local authority. Several Acts for paving of streets, the Strand were passed in the 14th century, and in the 16th century for the streets outside the City. In 1614 the citizens began to pave the margins of the streets before their doors, but the middle of the streets were laid with large pebbles very unevenly. In 1661 the money obtained from hackney coach licences, £5 for each annually, was applied to keeping them in repair. The use of squared granite blocks, with raised footways, was introduced by Acts of Parliament for Westminster in 1761, and for London generally in 1766. Within the last twenty years asphalt and wooden pavement have been largely substituted for granite in the principal thoroughfares.

Hackney coaches are first mentioned in 1625, when they were conveyed at fairs, and numbered altogether only 20. In 1652 their number was limited to 200, in 1662 to 400, in 1684 to 700, in 1715 to 800, in 1771 to 1000, and in 1779 to 1200. In 1832 the restriction of their number was abolished. The number of cab drivers in 1871 was 10,043, and of cabs 7818, of which 3295 were hansom and 4523 four-wheelers; in 1881 the number of drivers was 12,630, and of cabs 9652, of which 5805 were hansom and only 3847 four-wheelers. Omnibuses were first introduced in 1829. Many of the principal streets are too crowded for tramways, but in South London tramcars are more used than omnibuses, and there are also several routes in the northern and eastern districts. The Metropolitan and Metropolitan District Railway lines, which run partly underground, and form almost a complete belt round the "inner circle" of London, with several branches intersecting it, and others communicating with various suburban lines, have proved invaluable in relieving the throng of vehicles on the streets, and in affording rapid communication between important points; but the railway system in and around London has suffered greatly in directness from the absence of a complete plan embracing proper connecting links between the lines of the several companies. The annual number of passengers on the Metropolitan Railway is now about 60 millions. The Regent Grand Junction, and several other canals, besides connecting London with the internal navigation of

utaleans of transport for heavy goods between officials. In 1692 the metropolis, for his care of the road into eight postal districts, viz., Eastern Central chamber. He has n-Central (W.C.), Northern (N.); North-Western to this his person (W.), South-Western (S.W.), South-Eastern salaries of the metropolis (E.). In the E.C. district there are twelve town-clerk, and others daily, in the town portions of the other districts, proportion. It is to about 3 miles from the General Post-Office, eleven hospitality and in the suburban portions six deliveries.

SPACES.—London owes the possession of its finest while to rather to accident than to intention. Eastwards and general wards no effort was made to preserve any part of the insti- tutional and the beautiful plain of meadow land interspersed with flowing "commons" mentioned by Fitzstephen, or of the "immense mass of rest of densely wooded thickets," or of the "common fields" in the great fen, notwithstanding the riot of the citizens in the reign of Henry VIII. against the invasion of their rights by enclosure. Westward, however, the inroads of the builder were interrupted by the royal parks, which, lying adjacent to each other, cover an area of about 900 acres. St James's Park, 80 acres, transformed from a swamp into a deer park, bowling green, and tennis court by Henry VIII., extended and laid out as a pleasure ground by Charles II., and rearranged by Nash (1827–29), possesses beautiful combinations of water and foliage. Green Park, 70 acres, lying between St James's Park and Piccadilly, is unadorned except by rows of trees and by parterres of flowers bordering Piccadilly. Hyde Park, 390 acres, stretches westward from the district of Mayfair to Kensington Gardens. Originally forming part of the manor of Hyde, which was attached to Westminster Abbey, Hyde Park at the dissolution of the monasteries was taken possession of by Henry VIII. In 1652 the park, which then included a large portion of the ground now joined to Kensington Gardens and extended to 621 acres, was sold for £17,068, 6s. 8d., but in 1660 it was rebought by the Crown, having some time before this become the great "rendezvous of fashion and beauty." It possesses nine principal gateways, of which that at Hyde Park Corner on the south-east and the Marble Arch on the north-east present the most striking features. The former, designed by Decimus Burton and erected in 1828 at a cost of £17,000, consists of three imposing arches adorned with reliefs copied from the Elgin marbles. The Marble Arch, originally intended as a monument to Nelson, was first erected at a cost of £80,000 in front of Buckingham Palace, and was placed in its present position in 1851. With its fine expanse of grass, its bright flower beds and clumps of shrubbery, its noble old trees, its beautiful ornamental lake the Serpentine, its broad avenues crowded with equipages, its Rotten Row alive with equestrians, its walks lined with thousands of loungers of very various nationalities, professions, and grades of social position, Hyde Park in the height of the season presents a scene which in the brilliancy of its *tout ensemble* and its peculiarly mingled contrasts can probably be paralleled nowhere else. In the 17th and 18th centuries Hyde Park was a favourite meeting place for duellists, and in the present century has been frequently the scene of great political gatherings. To the west are Kensington Gardens, 360 acres, originally attached to Kensington Palace, and enlarged in the reign of George II. by the addition of nearly 300 acres taken from Hyde Park. They are more thickly planted than the "Park," and also contain an avenue of rare plants and shrubs, and several walks lined with flowering trees. Regent's Park in the north-west, 470 acres, occupying the site of Marylebone Park, which in the time of Elizabeth was used as a hunting ground, owes its preservation to the intention of George III. to erect within it a royal palace. It contains the gardens of the Zoological Society and of the Royal Botanic Society, as well as the grounds of a few private

villas. The northern half of the park is in summer devoted to cricket; in the south-east corner there is a flower garden of rather antique design; and in the south-west a portion bounded on the north by an artificial lake is let to private householders. To the north of Regent's Park there are other about 12 acres of open ground surrounding Primrose Hill, parks. 220 feet, commanding an extensive view of London. Battersea Park, 180 acres, formed (1852–58) at a cost of £312,890, on the south side of the Thames, besides a fine promenade along the banks of the river, several walks and carriage drives bordered with parterres, and a wide expanse for cricket and other amusements, contains a subtropical garden, which during August and September possesses much of the witchery of an ideal fairy-land. East London, after the enclosure of Finsbury Fields, had no special recreation ground until the opening of Victoria Park, which was sanctioned by an Act of Parliament in 1842, and was in 1872 increased to about 300 acres. Finsbury Park, 115 acres, formed by the Metropolitan Board of Works from the grounds of Hornsey Wood House at a cost of £112,000; Southwark Park, Rotherhithe, 63 acres, formed at a cost of £111,000; West Ham Park in the extreme east, partly purchased by the City corporation; Greenwich Park (see GREENWICH); and the gardens on the Thames Embankment, with various squares and semi-private gardens, sum up the other ornamental open spaces of London.

The Metropolitan Board, under various Acts of Parliament, have secured the exclusive right of the public in several commons and open spaces, which with the parks under their care comprise together an area of 1698 acres, giving with the royal parks and Battersea Park, Victoria Park, and West Ham Park a total of over 3000 acres, or about a twenty-fifth part of the whole metropolitan area. The principal public commons are Hampstead Heath, a wild hilly region now encroached on by buildings on all sides except the north and north-west, commanding fine views both of London and the country, and, with its clear bracing air and its unkempt and rugged beauty, breaking on the visitor with all the effect of a sudden surprise; Blackheath Common, 267 acres, a bare sandy expanse to the south of Greenwich Park, containing a good golfing course; Clapham Common, 220 acres; Wormwood Scrubs, 194 acres; the Tooting Commons, 207 acres; and Plumstead Common, 110 acres. The total sum expended by the Board of Works in the purchase, preservation, and adornment of parks and open spaces up to 31st December 1881 was £436,760. All the parks and open spaces already mentioned are included in the Metropolitan Board district, but outside this area there is in the neighbourhood of London a large number of uncultivated spaces to which the public have various rights, some of them of an obscure and undefined character. A return made to the House of Commons in 1865 gives the area of public commons within radii of 25 miles and of 15 miles of the metropolis, the area of those within the smaller circuit being 13,301 acres. Of Epping Forest 5600 acres have been secured to the public by the corporation of the City, and in 1871 an Act was passed for the preservation of Putney Heath and Wimbledon Common, but Hounslow Heath, of old the favourite resort of highwaymen, and at one time over 4000 acres in extent, is now nearly all under cultivation. Richmond Park, the grounds of Hampton Court Palace, the gardens at Kew, the fine surroundings of the Crystal and Alexandra Palaces, the cricket grounds at the Oval and Lord's, may practically be also reckoned among the public parks of London. In addition to this the river Thames itself supplies facilities for recreation which are safe from the inroads of the builder; and all round the metropolis there are numerous footpaths through the open fields.

WATER SUPPLY.—For two centuries after the Conquest

Water supply.

London obtained a sufficient supply of pure water partly from the rivers or streams which passed through it and partly from wells sunk into the sands above the chalk. Holywell, Clerk's Well (Clerkenwell), and St Clement's Well (near St Clement's Inn) are mentioned by Fitzstephen as those "of most note." In 1236 the magistrates purchased from Gilbert Sandford the liberty to convey the waters of the Tyburn from Paddington in leaden pipes to the city, and a great conduit of lead castelled with stone was begun in West Cheap in 1285. Various other conduits were built in the 14th and 15th centuries, some for the water of the Thames, from which also the inhabitants were supplied by the city company of water-bearers, who brought it in leathery panniers slung on horses. In 1582 a great step in advance was taken by Peter Moris, a Dutchman, the real originator of the Thames water companies, who erected a "forcier" on an arch of London Bridge to convey the Thames water into the houses in the east end of the city as far as Gracechurch Street; in 1594 another was erected near Broken Wharf for West Cheap, Fleet Street, and the district round St Paul's, and in 1610 a third at Aldersgate without the gate. Moris, who obtained the lease of one arch of London Bridge for five hundred years at a rental of 10s. per annum, and two years later the use of another arch, erected for his purpose very ingenious machinery; and the works continued until 1701 in the possession of the family, who after amassing large wealth sold the lease to a company for £30,000. They ultimately occupied four arches, and continued till 1822, when the supply was purchased by the Southwark Company for £10,000. In 1605 an Act was passed for supplying the northern districts from springs near Ware in Herts. This enterprise was in 1609 undertaken by Hugh Myddleton, who, when his funds became exhausted in 1612, received the necessary money from James I. on condition of his sharing in the profits. With this assistance the reservoirs at Clerkenwell supplied by the New River were opened in 1613. In 1630 a scheme to bring water to London and Westminster from Hoddesden in Herts was promoted by aid of a lottery licensed by Charles I. on condition that the

promoters should pay £4000 per annum into the king's treasury. Strype, writing in 1720, mentions that "there is not a street in London but water runs through it in pipes conveyed underground, and from those pipes there is scarce a house whose rent is £15 or £20 per annum but hath the convenience of water brought into it," while "for the smaller tenements there is generally a cock or pump convenient to the inhabitants." In 1721 the Chelsea Water Company began to supply water from the Thames to Westminster and the parts adjacent, and in 1783 the supply of south London was supplemented by the erection of the Lambeth water-works opposite Charing Cross. The Vauxhall Company was established at Vauxhall Bridge in 1805, the West Middlesex near Hammer-smith in 1806, the East London on the River Lea at Bow in the same year, the Kent on the Ravensbourne at Deptford in 1810, the Grand Junction at the Grand Junction Canal in 1811, and the Southwark at London Bridge in 1822. For several years before the interference of parliament the companies had agreed to restrict themselves to separate localities. The Acts of 1847 required the companies to provide pure and wholesome water for the use of the inhabitants in the districts supplied by them, and also to provide water for general use. An Act passed in 1852 compelled the removal of the companies beyond the tidal limits of the Thames, contained regulations as to rates, enforced thorough filtration, and endeavoured to make provision for a constant supply. The rates, which differ in the various companies, were in some respects amended by the Act of 1871; but, as it fails to guard against claims for back dividends, no sufficient guarantee is provided against the raising of the rates. These are charged chiefly on the value of the houses, but the Acts do not distinguish with sufficient clearness between the gross annual value and the rental. A proposal in 1880 to purchase the rights of the companies, whose capital was then a little over £12,000,000, for £34,160,000, failed to commend itself to a committee of the House of Commons.

Their accounts being made up at different periods, it is impossible to give comparative returns for the companies; the following are the figures (Table V.), as best they can be stated, for two years:—

	Ordinary Capital.	Preference and Loan Capital.	Total Capital.	Total Expenditure.	Income.	Working Expenses.	Dividends.
1871-2..	£7,561,624	£2,520,340	£10,081,964	£10,137,710	£392,610	£389,258	£663,352
1880-1..	9,087,917	3,448,981	12,536,898	12,612,569	1,532,784	610,899	921,885
Increase..	1,526,291	928,641	2,455,032	2,474,859	540,174	221,641	318,533

Within ten years the increase of capital has thus been about 24 per cent., or 2½ per cent. per annum, the increase of the income 54 per cent., or 5½ per cent. per annum, and of the expenses 57 per cent., or 5½ per cent. per annum. Thus, while in 1871 there was a capital of 10 millions, gaining 6 per cent. profits, in 1881 there was a capital of 12½ millions producing 7½ per cent. Within the last two years the value of the property has been increasing at a more rapid ratio, and probably at the rate of £1,250,000 per annum; but, as on account of the proposals to buy up the rights of the companies they have at present special reasons for curtailing expenses and delaying the carrying out of all but essential improvements, it is impossible to know how much of the increase is temporary and artificial.

The problem of future supply.

According to Dr Frankland the water of the Thames and the Lea, notwithstanding the most efficient possible filtration, is, on account of sewage pollution, becoming less and less fit for domestic use, about one-half of the water at present supplied being already grossly polluted, and a very large proportion of the remainder occasionally polluted. He therefore recommends that the supply of water

for domestic use should be taken from the springs of the basin before they reach the river. At the present rate of the increase of London the supply required will, however, within forty years exceed that which may be obtainable in the whole Thames basin in times of summer drought, such as may occur in any year, and thus in a future not far distant a means of storage must be provided, or a new source of supply discovered, involving an outlay which would at least double the rates on the present rental. The Kent Company, which obtains its supply from the chalk wells, is the only one possessing wholly unpolluted sources, but the New River Company also obtains about one-tenth of its supply from springs, the remainder being obtained from the Lea. The East London Company obtains its supplies from the Lea and Thames, and the other companies from the Thames alone. The following table (VI.) gives certain particulars:—

Average Daily Supply from Thames.	Other Sources.	Average Supply from Thames.	Other Sources.	No. of Supplies to House.	Houses on Constant Supply.	Estimated Population Supplied.	Subsidiary Storage.		Filtered Storage.		Miles of Mains in the Metropolis.	Miles of Mains Constantly Charged.
							Capacity.	Area.	Capacity.	Area.		
110,000,000	Not Estimated.	68,000,000	72,000,000	622,000	186,000	4,600,000	Acres. 467½	Gals. 1,264,356,000	Acres. 46	Gals. 150,087,000	2,707	750

Old  
methods  
of light-  
ing.

**LIGHTING.**—From 1416 the citizens of London were under an obligation to hang out candles between certain hours on dark nights for the illumination of the streets; and in 1661 a special Act of Parliament was passed to enforce the custom. The corporation in 1684 granted a licence to Edward Heming, the inventor of oil lamps, for the sole supply of the public lights for twenty-one years, but the duty was then once more assigned to the individual citizens. A second agreement with contractors not proving satisfactory, the corporation in 1736 obtained from parliament permission to erect lights where they thought proper, and to levy a rate, which in that year yielded £15,000. Gas-lighting was in 1807 introduced in Pall Mall by the erection of a small apparatus to supply the lamps on the one side of the street, the other being still lighted with oil. In 1810 the Gas Light and Coke Company received a charter permitting it to supply gas to any persons within "the cities of London and Westminster, and the borough of Southwark," and as the result of their enterprise Westminster Bridge in 1813 was lighted with gas, and in 1811 the whole of the streets of St Margaret's parish. The City of London Gas Company was formed in 1817, and soon afterwards other seven companies. After several years' wasteful competition the companies came to an agreement in 1857 to restrict themselves to separate localities. This led to the Metropolitan Gas Act of 1860, the only effectual provisions of which were those in reference to the quality of the gas. The City of London Gas Act of 1868, limiting the price of gas within the City to 3s. 9d. per 1000 feet, except in certain cases, was the only other measure of a restrictive character passed before 1876, and previous to this the companies, by amalgamation, and through the favourable terms on which they were allowed to increase their capital and to raise new shares, had enormously increased the value of their dividends. The Act of 1876, from the provisions of which the London Gas Company is exempt, adopted a sliding scale of dividends, one half of the profits, after a 10 per cent. dividend had been paid, going to the shareholders, the other being applied to reduction in the price of the gas, it being also provided that the price should not be more than 3s. 9d., and that when additions were made to the capital the shares should be put up to auction. The experimental introduction of the electric light by the commissioners of sewers of the City, and by the Metropolitan Board (for the Thames Embankment and some of the bridges), has led the gas companies to provide better lights in some of the more important streets.

The following table (VII.) will show that the prosperity of the companies has not been affected by the legislation of 1876, and as yet has not materially suffered from the threatened competition of electric lighting:—

	Total Gas Companies. Year ending December 31, 1880.	Totals, Year ending December 1874.	Increase or Decrease— from 1874 to 1880.
	£	£	£
Amount of capital authorized .....	12,050,719	10,482,900	+1,567,819
Paid up capital .....	10,751,961	8,887,286	+1,864,675
Capital remaining to be paid up.....	1,298,757	1,595,614	-329,857
Loans authorized .....	3,361,167	2,058,667	+1,302,500
Loans capital remaining to be borrowed.....	1,303,805	529,455	+774,350
Amount of capital on which 10 per cent. is paid .....	8,032,720	5,216,800	+2,815,920
Profit income .....	3,988,543	3,703,198	+285,345
Total expenditure .....	2,791,858	2,767,268	+24,590
Total gas sales .....	3,015,144	2,914,800	+100,344
Contract for public lighting.....	221,271	268,297	-47,026
Coal authorized .....	1,298,254	1,444,996	-55,742
Gas sold for private lights .....	17,012,925	11,618,859	+5,394,066
Gas sold for public lamps.....	1,121,138	1,075,595	+45,543
Public lamps.....	60,316	54,119	+6,197

<sup>1</sup> By amalgamation the companies have now been reduced to four:—Gas Light and Coke Company, paid up capital £7,515,000; South Metropolitan Gas Company, £1,831,990; Commercial Gas Company, £675,845; London Gas Company, £732,128.

**FIRE EXTINCTION.**—Until 1866 the duty of extinguishing fires was in the hands of the fire insurance companies, which in 1832 united in support of one brigade for the whole of London, but only kept a comparatively small establishment, in the central districts of the metropolis. The other districts were protected by small hand-engines kept up by the parochial authorities according to the 14 Geo. III. c. 78. Since the staff of the fire insurance companies was placed under the care of the Metropolitan Board, the number of stations has been increased from 17 to 53, with 4 floating stations, while 11 movable stations have also been provided; the number of engines has been increased from 11 steam and 27 manual to 3 floating engines, 38 steam land engines, and 115 manual; and the number of men has been increased from 180 to 536, in addition to 68 coachmen and pilots. The board has also undertaken the duty of protecting life from fire, which previous to 1867 was discharged by a society supported by voluntary subscriptions, and they at present maintain 137 fire-escapes, which are stationed during the night in the most prominent parts of the metropolis. The total receipts of the brigade in 1880 was £31,545, and the expenses £38,980, of which £56,021 was defrayed by the board, £10,000 was paid by the treasury, and £21,464 was contributed by the insurance companies, at the rate of £35 for every £1,000,000 insured by them. In 1881 the expenses were over £100,000, of which over £80,000 was defrayed by rates. The number of persons endangered by fire during 1881 was 154, of whom 114 were saved and 40 lost their lives. The following table (VIII.) gives a classification of fires since 1874:—

	Number of Fires.			Percentage.	
	Serious.	Slight.	Total.	Serious.	Slight.
1874	154	1419	1573	10	90
1875	163	1366	1529	11	89
1876	166	1466	1632	11	89
1877	159	1374	1533	10	90
1878	170	1489	1659	10	90
1879	159	1559	1718	9	91
1880	162	1709	1871	9	91
1881	167	1824	1991	8	92

**SANITARY ARRANGEMENTS.**—Until 1531 no provision was made for the construction of underground main sewers, notwithstanding that in 1290 the exhalations from the Fleet overcame the incense burnt at the altars in the neighbouring churches, and that in 1307 the river, on account of the accumulation of filth, had become inaccessible for ships. The Act of Henry III. in 1531, which provided for the appointment of a commission of sewers, was renewed in 1518 by Edward VI., and extended in its application by James I. in 1607; and subsequently separate commissions were granted as the population extended to other districts. The most important work of the old commission of sewers was the bridging over of the Fleet in 1637. In 1841 this sewer, which drained an area of over 400 acres, was widened at a cost of about £47,000, and at its mouth an iron culvert was provided which carried its discharge into the middle of the Thames.<sup>1</sup> Other main sewers were constructed, but the bridging of them over was carried out slowly and in a very imperfect manner. In early times the nuisances were carried away by the scavengers and the sewage received into wells, which when full were pumped into the kennels of the streets. Until 1848 the discharge of house sewage into the main drainage was forbidden, and the construction of cesspools enforced, the majority of which were unprovided with overflow drains, but after 1810 there was considerable improvement in connexion with the introduction of better arrangements for a supply of water. Under the auspices of the Metropolitan Commission of Sewers, created by the Act of 1848, a more satisfactory system of local drainage was enforced; but its action in regard to the main sewage discharge was so dilatory that the pressure of public opinion led to the Metropolitan Local Management Act of 1855 providing for the creation of the Metropolitan Board of Works, in which was vested the care of the main sewers, and to which was entrusted the construction of works for their discharge at a distance from London regarded as sufficient to prevent the pollution of the river. Works were commenced in 1859, and completed in 1865 at a cost of £4,607,000, pro-

litan  
Board.

viding three lines of intercepting sewers on the north side of the river, which convey the discharge 11 miles below London Bridge, and two lines on the south side, which convey their discharge 4 miles farther down. These works comprise 80 miles of main intercepting sewers, in addition to four pumping stations to raise the sewage from the lower levels. The total length of the main street sewers entrusted to the board was about 165 miles, one-fifth of which consisted of offensive open sewers, while many of the others were of most defective design or out of repair. The total cost of repairing these sewers, and connecting them with the new main drainage system, was estimated at £800,000, and works to the value of £750,000 have been executed. The sum expended on main drainage and main sewers up to 31st December 1881 was £5,684,470. The opinion seems to be increasing that the present method of getting rid of the sewage of London is radically wrong, and undoubtedly the sewage discharge may reach proportions which may absolutely demand a new supplemental scheme. For the four years ending 1878 the average daily sewage discharge was 122½ millions of gallons, in 1878 it was 157½ millions, and it is now estimated at 180 millions.

Thames conservancy.

The conservancy of the Thames was in 1857 transferred from the corporation to a body of twelve, nominated by various authorities, and presided over by the lord mayor; and in 1867 the conservancy of the upper reaches from Staines to Cricklade was vested in a board, of which the conservators of the lower reaches formed the majority. Under the auspices of these two boards not only has the navigation of the river been very much improved, but very stringent care has been exercised to prevent its unnecessary pollution. In 1868 the Lea was also placed under the control of a conservancy board. The expenses of the boards are defrayed by tonnage dues, tolls, pier dues, fines, and licences, and contributions from the canal and water companies.

Street sanitation.

The sanitary condition of the streets and houses is under the care of vestries and district boards, but great variety exists in regard to the efficiency with which the work is performed.

Cemeteries.

An Act passed in 1845 provides for the prohibition of interment in any of the cemeteries within the metropolitan area by order in council, and forbids the construction of new burial grounds within 2 miles of the metropolis except on the approval of the secretary of state. The power of constructing cemeteries for their several districts is granted to the vestries, who may borrow money for this purpose from the Public Works Loan Commissioners, and are required to appoint a board for their management. The commissioners of sewers for the City of London are the burial board for the City parishes. The secretary of state has the power to issue regulations in regard to the construction of cemeteries and the arrangements connected with interment. Among the more important suburban cemeteries are Kensal Green (in which many eminent persons have been interred), Brompton, Hampstead, Highgate, Abney Park, Nunhead, and Norwood.

Climate.

HEALTH.—Apart from the deleterious influence of smoke and defective sanitary arrangements, London must be

regarded as exceptionally healthy. Although subject occasionally to rapid alternations of temperature, the climate is generally mild and according to the seasons equable, with an early spring and a long autumn. The following table (IX.) gives a summary of Greenwich meteorology for thirty-two years, 1849–80 :-

Weekly Movement of Air in Miles	Yearly Fall of Rain in Inches	Mean Dryness of Atmosphere	Mean Temperature for the Year	Mean Temperature for Quarters ending in			
				March.	June.	Sept.	Dec.
1849	24.8		49.1	39.9	62.1	60.1	44.1

In 1306, when the population did not exceed 50,000, Smoke the citizens of London petitioned Edward I. to prohibit the use of sea coal, and he passed a law making the burning of it a capital offence. John Evelyn, in *Fumifugium*, written in 1661, complains that on account of the increase of coal smoke the gardens no longer bear fruit, and instances various cases in which the smoke had been prejudicial to health, but the influence of smoke in increasing fogs and intensifying their evils seems not to have been appreciable. The smoke producing area has since then increased from about 3 square miles to over 100 square miles, and the average daily consumption of coals in domestic fireplaces has mounted to about 27,000 tons, or in winter probably to 40,000 tons, which in certain states of the atmosphere produces a cloud of smoke resting for days over the central districts of the town, and shutting out the sun, even when it does not descend in foggy weather as a thick, impenetrable, and partly poisonous mass of darkness. During the fogs of 1879–80 asthma increased 220 per cent. and bronchitis 331 per cent., and in the week ending February 13, 1882, the death-rate, owing to the dense fogs, rose from 27.1 in the previous week to 35.3, diseases of the respiratory organs rising to 991, the corrected weekly average of this class of diseases being 430. The evil is mainly due to the smoke of domestic fireplaces.

The death-rate of London has steadily declined since the beginning of the century, when it was first exceeded by the birth-rate. A record of the births and deaths of London entitled "Bills of Mortality" was made by the parish clerks in the plague year of 1593, and from 1603 was continued even after the returns had begun to be published by the registrar-general. Though they only included the births of persons baptized according to the forms of the Church of England, and the deaths of persons buried in consecrated ground within the parishes included in the "Bills," and were in many cases very carelessly compiled, they place it beyond doubt that even in years when London was exempt from the plague the rate of mortality required a large immigration from the country to take the place of those who died in London. Previous to 1593 the great plague years were 1319, 1361, and 1369.

The following table (X.) shows the number of births and deaths in the great plague years of the seventeenth century, and the average annual number for every decade in the 18th century :-

Years.	Total Deaths.	Deaths from Plague.	Births.	Excess of Deaths.	Average 10 Years ending	Deaths.	Births.	of 10 Years ending	Average 10 Years ending	Deaths.	Births.	Excess of Deaths.
1593	17,844	10,662	4,021	13,823	1710	461	5,898	1760	22,001	17,156	4,845	
1603	42,042	36,269	4,789	37,253	1720	909	6,798	1770	21,943	19,784	2,159	
1625	54,265	35,417	4,781	47,482	1780	492	9,289	1780	23,851	19,218	4,633	
1698	23,350	10,400	9,522	13,827	1740	5492	16,850	9,662	1790	23,080	21,477	1,603
1805	97,306	68,696	9,967	87,339	1750	5352	14,167	10,805	1800	24,270	22,605	1,665

The average mortality of London in 1881 was 21.6 per 1000, or 1.1 less than that of the twenty other large towns of England, while the rate for England was only 20.5. It is to be remembered that London contains a comparatively small proportion of working class population. Its sanitary condition is still very far in advance of that of Paris, where at present the death-rate is about 180 for 100 in London. The registrar-general calculates that according to the density of London its normal death-rate should be much lower than

it is, but, besides the fact that mortality is influenced by other causes than sanitary arrangements, the extended area augments the evil results of density, and the lesser density in some districts cannot counterbalance the excessive crowding of others. Table XI. gives the annual rate of mortality per 1000 persons living for various periods, and Table XII. the number of births and of deaths from the principal zymotic diseases and from all causes :-

TABLE XI.—Annual Rate of Mortality, 1851-81.

Area in Square Miles.	Persons to a Square Mile, 1881.	Annual Rate of Mortality per 1000 Persons living.

**Marriage-rate.** The mean marriage-rate for ten years 1870-79 was 19·2, and for 1880 it was 18·1. The percentage of children born out of wedlock in 1880 was 3·9, that for England being 4·8.

**Provision markets.** **MARKETS AND FOOD SUPPLY.**—A regulation passed in 1277 ordained that no market should be kept on London Bridge or elsewhere except in places specially appointed for the purpose, and that no person should buy wares in Southwark that were to be bought in the City. In 1322 a decree was issued by the mayor that none should sell fish or flesh "out of the markets appointed, to wit, Bridge Street, East Cheap, Old Fish Street, St Nicholas shambles, and Stocks market"; and in 1328 a charter was granted to the corporation by Edward III., conveying to it the sole right to establish markets within 7 miles' circuit of the city. In 1345 a proclamation was passed that poultry instead of being sold in lanes or hostels should be brought to Leaden Hall, and in the same year it was decreed that butchers and fishmongers should sell in the enclosed place called the "Stokkes," and not in the king's highway. After Acts passed in 1351 and 1382 on behalf of aliens and foreigners, all regulations formerly made in reference to the sale of provisions in London were repealed, and the dealers placed under the control of the mayor and aldermen, thus confirming a system of public markets and bazaars even for the retail trade, which remained almost inviolate till the time of Edward VI., up to whose reign there was, according to Stow, scarcely such a thing as a shop between Westminster and St Paul's. The system, though now broken up even in regard to provisions so far as the retail trade is concerned, remains intact in regard to the vending of certain provisions wholesale, and still exercises a considerable influence on general retail. The principal markets mentioned by Stow are Smithfield, Bartholomew Fair, Leaden Hall, Grass Church (Grace Church) market, chiefly for corn, meal, and cheese; East Cheap flesh market, the adjoining alley to which, Red Rose Lane, had by this time received the less idyllic title of Pudding Lane, on account of the butchers making use of it for the disposal of the offal before transferring it to their dung-boats on the Thames; Newgate market for corn, afterwards for meat; St Nicholas shambles; Stocks market, established in 1282 on a place occupied by public stocks, and rebuilt in 1410, for flesh, fish, and poultry; and the fish market in Old Fish Street. He also states that in 1302 bread was sold in Bread Street in the open market. Before the great fire Stocks market was occupied by greengrocers, the important vegetable market at Honey Lane had, also been established, and markets, chiefly for meat and fowls, were held at Holborn Bars and outside Temple Bars. The increase of the population led in 1657 to the establishment by Lord Clare of Clare market, which, though now frequented only by a very humble class of buyers, was declared a free market by a special Act of Cromwell's

parliament, and was for a long time one of the principal markets for all kinds of provisions. Other markets subsequently established were those of St James by the earl of St Albans, Bloomsbury by the earl of Southampton, Brook market by Lord Brook, Hungerford market, Newport market, Haymarket, and Mayfair. Newport market for meat still exists, but the others have been gradually superseded. The principal markets now existing are Smithfield (central meat market and poultry market), Leadenhall (poultry and game), Billingsgate (fish), Covent Garden (fruit and vegetables), the cattle markets at Copenhagen Fields and Deptford, the Bermondsey leather market, and the Cumberland, Smithfield, and Whitechapel hay markets.

A market for horses and cattle was held at Smithfield (*Smooth-Old field*) in the time of Fitzstephen, and doubtless long anterior to Smith. The priory of St Bartholomew in Smithfield obtained from field. Henry II. the privilege of a fair for drapers, which was kept three market days yearly, originally in the churchyard at a considerable distance from the place occupied by the cattle market, and latterly became a scene of great riot, until it was abolished in 1863. A year later the cattle market was removed to Copenhagen Fields. There were 80 butchers in London and suburbs in 1533, each of whom killed 9 oxen weekly, which in forty-six weeks, none being killed in Lent, would amount to 33,120 yearly. In John Erskine's *Brief Note of the Benefits of Fish Days* (1598), it is estimated that 60 but freemen of the city, killed each 5 oxen weekly, or altogether per week, and that the foreigners or non-freemen killed four as many, or 1200 weekly, the total number of cattle annually killed being thus 69,000. By Richard II. a law was passed enacting that no flesh should be killed in London but at Knightbridge or such like distance from the city, but in the time of Stow the slaughter-houses of the freemen butchers were in Pentecost Lane adjoining St Nicholas shambles and near the Butchers' Hall. Probably the arrangements in regard to slaughter-houses were then more advanced in London than they are now, for, although sufficient slaughter-houses to dispose of all the cattle sold at Copenhagen Fields have been erected adjoining the market, a very large number of cattle are still killed in underground cellars, which, notwithstanding the superintendence of the Board of Works under the Slaughter-Houses Act of 1874, are in the majority of cases totally unsuited for the purpose. The number of these slaughter-houses before the passing of the Act, when they were licensed by the justices, was 1429; but they have now been reduced to a little over 900. The following table (XIII.) gives the average yearly number of sheep and cattle sold at Smithfield at various periods from 1781 to 1854, when the market was removed:—

	Cattle.	Sheep.		Cattle.	Sheep.
1781-1740	96,601	593,713	1849-1846	185,129	1,228,850
1741-1760	86,271	648,684	1847-1851	226,858	1,480,614
1761-1800	124,685	767,973	1852-1854	266,579	1,521,923
1801-1810	131,318	901,340	1854	266,008	1,509,590

The market at Copenhagen Fields, Holloway, covers upwards of 20 acres, and was erected at a cost of £441,000, with accommodation for 6616 bullocks, 34,980 sheep, 1425 calves, and 900 pigs. Fields Deptford foreign market, which occupies the site of Deptford dock and yard, and was bought for £100,000, has an area of 23 acres. The following table (XIV.) gives the number of cattle, sheep, and pigs marketed at the metropolitan markets since 1870:—

	Cattle.				Sheep.				Pigs.			
	Home Supply.	Foreign Supply.	Total.	Total.	Home Supply.	Foreign Supply.	Total.	Total.	Home Supply.	Foreign Supply.	Total.	Total.

**Central meat market.** The Central London meat market, opened in Smithfield in 1868 at a cost of about £250,000, to supersede Newgate market, is built in the Italian Renaissance style, with towers at the four corners, and occupies about 3 acres, its length being 625 feet and its breadth 240. Below the market area there is a railway terminus. To the west of the meat market another one-third its size was opened in 1875 for poultry and provisions. From 1868 to 1875 the toll received from the meat market increased from £14,220 to £18,272, or 28½ per cent., and with the addition of the poultry and provision market it had increased in 1880 to £24,310, or 71 per cent. The total amount of meat sold in the market in 1879 was 213,614 tons; in 1880 the total amount was 221,448 tons, of which 107,326 tons were country-killed, 80,905 town-killed, 7381 foreign, and 25,836 American, the amount of American meat in 1876 being only 5513 tons. A large quantity of meat is conveyed to the butchers direct without entering the market, and several butchers also buy their cattle and get them killed privately. As, moreover, the cattle markets and the meat market supply towns and villages beyond the metropolitan area, there is a double impossibility of forming from these sales an estimate of the actual amount of butcher's meat consumed in London.

**Leadenhall market.** Leadenhall, which according to Stow belonged in 1309 to Sir Hugh Neville, and had been used as a market before it came into the possession of the city in 1411, was enlarged in 1444 by an addition for a granary in connexion with the corn market which had been removed to it from Cornhill, the clothes market also following before 1503; and before 1553 the foreign butchers who formerly stood in the High Street off Lime Street had been ordered to take stalls in it. A great part of it in the time of Stow was used as a wool market, but afterwards it became the principal provision market in the city; and, according to Pennant, the Spanish ambassador told Charles II. that he believed there was more meat sold in that market than in all the kingdom of Spain. The Leadenhall underwent improvements in 1718 and 1814; and in 1881 a new structure of elegant design, with an area of 26,900 square feet, and erected at a cost of £50,000, was opened as a market for fowls and game, the principal commodities sold at Leadenhall for many years.

**Billingsgate.** Billingsgate, the great fish market of the metropolis, was from an early period a harbour for small ships and boats, and in the time of Stow had almost superseded its great rival Queenhithe, which was in the possession of the Crown. As it grew in importance fish stalls were erected in its neighbourhood, but the original market for fish was in Fish Street; and Friday Street, Cheapside, which received its name from being inhabited by fishmongers who served Friday's market, is mentioned as early as 1303. The Act of 1699, which made Billingsgate a "free market for fish," to some extent interfered with the ancient control of the fishmongers, although the custom of selling fish there had been introduced long previously. Until 1846 Billingsgate was a mere assemblage of wooden sheds. The building erected in that year was succeeded by another in 1847, with an area of 39,000 feet instead of 20,000; but, on account of the deficiency of its communications and its defective internal accommodation and arrangements, the market is totally inadequate. Among several abortive efforts to establish other markets for fish was the Columbia market, which was completed in 1869 by the Baroness Burdett Coutts for over £200,000, and presented as a fish market to the City, but failed to attract salesmen. The City authorities have the intention to utilize the vegetable market in course of erection at Smithfield as a fish market, and a scheme is also being promoted for a fish market in the parish of St Paul, Shadwell. A fish and vegetable market has been established by the Great Eastern Railway Company at Canning Town. The quantity of fish brought to London by rail is the given by the markets committee prior to 1866, but in 1866 the quantity brought by water alone was 108,739 tons. In 1869 the total brought by water and rail was 182,004, in 1870 it was 117,193, in 1875 only 94,949, but since 1877, when the new market was opened, it has gradually increased from 107,168 to 130,629, or nearly 2000 tons less than in 1866; and scarcely 12,000 more than were brought in 1848 by water alone. There has of

late years been a more rapid increase in the quantity of water-borne fish, but the amount brought by rail is at present about two-thirds of the whole. Thus, with a population which since 1851 has increased by two-fifths, the fish supply has practically remained stagnant, while, owing to delay in consequence of increased pressure of traffic, the fish often deteriorate so as to be unfit for human food.

Covent Garden market, for vegetables, fruit, and flowers, which Covent occupies the site of a convent garden belonging to Westminster Abbey, seems to have been used as a market very early in the 17th century, and it received a considerable impulse from the discontinuance of Stocks market on account of the building of the Mansion House and also of Honey Lane market, which in 1823 was superseded by the City of London school, while since the removal of Hungerford market to make way for Charing Cross station it has remained the only vegetable and flower market of importance in the metropolis, although vegetables of a cheap kind are sold at the Borough and Spitalfields markets, watercresses at Farringdon market, which superseded the Fleet vegetable market in 1824, and potatoes at the station of the Great Northern Railway. Until 1828 Covent Garden market consisted of an unsightly array of sheds. The present building, erected by the duke of Bedford, though lately much improved, is quite inadequate for its requirements, while the arrangements for the disposal of mud and refuse are very reprehensible.

Tattersall's, Knightsbridge, established by Richard Tattersall in Tatter-1780, is one of the principal marts in England for riding and sell's, carriage horses, and may be regarded as the headquarters of the turf.

One of the principal difficulties connected with the establishment of new markets in London lies in the inconvenient railway arrangements, which render it impossible to obtain a site that shall have sufficient and direct communication with the several districts of England and with the Continent. The poorer classes obtain a cheaper supply of vegetables and other provisions from costermongers, and itinerant vendors, who either occupy stands in special localities, especially in the East End, and in High Street (Lingdon), Hampstead Road, Edgeware Road, and York Road (Sofers Town), or hawk them through the streets. The capital possessed in 1861 by these vendors, who then numbered 41,040, was estimated at £40,000, their gross amount of annual trade at £2,700,000, and their annual gains at £900,000. Since that period their numbers, capital, trade, and gains have probably increased at least one-third.

**COMMERCE AND INDUSTRY.**—London, which was a port of some consequence in the time of the Romans, is spoken of by Bede as the "mart of many nations resorting to it by sea and land." The Hanse merchants, protected by a clause of Magna Charta, began in the 13th century to frequent London in large numbers, and, after obtaining liberty in 1236 to land and store the wool imported by them, are supposed to have settled in the Steelyard about 1250, but as early as the 8th century they had begun to frequent Billingsgate, and in 978 King Ethelred had conferred certain privileges on them and on other traders. Probably by the time of Fitzstephen London had become the most renowned mart of the world, with the exception perhaps of Antwerp and Bruges. The foreign merchants received a special charter from Edward I. in 1303, and, notwithstanding occasional interference with their privileges, the Hanse traders, who had erected extensive factories and storehouses near their "Gildhall," gradually absorbed the greater portion of the foreign trade of London, until the incorporation of the Merchant Adventurers of England, in 1505, for trading in wool to the Netherlands. The trade with the Levant, which had

become of some importance in the 15th century, soon largely extended, and commercial intercourse was also opened up with Barbary, Guinea, and Brazil. After the abolition of the special privileges of the Steelyard merchants, the trade in wool was transferred almost entirely to the Merchant Adventurers, the annual export of English wool and drapery to Antwerp and Bruges in 1566 being estimated at over £2,000,000. The close of the 16th century was marked by the rapid extension of maritime discovery, and the spirit of enterprise was stimulated by the grant of monopolies to those companies which should first open up communication with undiscovered countries. One of the earliest and most successful of the great maritime companies was the Russian, incorporated in 1553, which, besides establishing an extensive commerce with the ports of Russia, had an overland trade with Persia. The foundation of the Royal Exchange by Gresham in 1566 marked an era in the commercial history of London; and the destruction of Antwerp by the duke of Parma in 1585 left it without a rival as the emporium of Europe. The settlement of many of the Flanders merchants in England gave a great impetus to the manufacture of silks, damasks, and other fine cloths, but from the time of the expulsion of the Steelyard merchants by Elizabeth in 1597 the development of the maritime trade of London was solely in the hands of English companies. The incorporation of the Turkey Company in 1579, of the East India Company in 1600, of the Virginia Company in 1606, and of the Hudson's Bay Company in 1670 must be regarded, not only as the most important events connected with the growth of the port in the 17th and 18th centuries, but as of prime consequence in relation to the social and political history of England.

Present  
trade.

In the trade of London there is a large excess of imports over exports, arising from the fact that it is specially a mart, and is removed from proximity to any large manufacturing district. The value in 1880 of the total trade of Liverpool, £191,489,838, was nearly equal to that of London, which was £191,043,836, but the value of the imports of London exceeded those of Liverpool by nearly £31,000,000, while the exports of Liverpool exceeded those of London by about £31,000,000. London has almost a monopoly of the trade with the East Indies and China, and has thus become the chief emporium for tea, coffee, sugar, spices, and indigo, and for silks and Eastern manufactures. A great part of the overland trade of London with India has till quite recently been carried on *via* Southampton, which, and also Folkestone, Newhaven, and Dover, may be regarded as virtually ports of London. The value of the imports of Folkestone, Newhaven, and Dover in 1880 amounted together to £24,485,034, and their exports to only £4,432,244: the imports of Southampton were valued at £9,205,183, and its exports at £9,306,326. In the Mediterranean and Levant trade London has now a powerful rival in Liverpool. From European and Asiatic Turkey London imports corn, dried fruits, madder, and various other special products; from Greece currants and olive oil; from Italy olive oil, wine, sumach, oranges, and lemons; from Spain wine and dried fruits; from Portugal and the Azores oranges and wine. Nearly the whole of the French trade with England is concentrated in London, the imports including all the special French manufactures, and large quantities of butter, eggs, vegetables, and corn. It is, however, largely carried on through the southern ports, the value of the imports of silk

to Folkestone in 1880 being £3,614,014, and those of London only £260,646, while the imports of eggs at Newhaven greatly exceed those of London, as do also the imports of butter and eggs at Southampton. London absorbs the greater part of the Baltic imports to England, especially timber, corn, cattle, wool, and provisions, the tonnage of the shipping that entered from Germany in 1881 being 634,741, from Belgium 249,161, from Sweden 416,997, from Norway 201,056, from the northern ports of Russia 401,076, and from Denmark 135,634. The tonnage that entered from the southern ports of Russia only amounted to 50,883, but much of this trade is carried on *via* Southampton. The chief imports from Russia are corn, tallow, timber, hemp, linseed, and wool. The fact that the staple manufacture of Lancashire is cotton has enabled Liverpool to gain a superiority over London in the United States trade, with the exception of imports of tobacco from Virginia; but the shipping that entered London from the Atlantic ports of the United States in 1881 had a burden of 670,079 tons, and from the Pacific ports of 3248 tons. From Central America London obtains its chief supply of the finer woods, and also jalap, sarsaparilla, indigo, coffee, and Peruvian bark, and from South America sugar, hides, india-rubber, coffee, diamonds, and various drugs. From Canada the port receives timber, corn, cattle, and provisions, from the Australian islands wool, oil, gold, copper, tin, provisions, and cattle; and it possesses more than half the trade of England with the West Indies, the principal imports being sugar and molasses, fruit, rum, coffee, cocon, fine woods, pimento, and ginger.

On account of the burning of the records at the custom-house, and Foreign the absence of regular parliamentary returns, it is impossible to give and a continuous summary of the progress of the shipping before 1816, colonial but the following table (XV.) gives the returns of the shipping trade, engaged in the foreign and colonial trade in various years from 1693 to that date, and the yearly average for subsequent periods:—

	Entered Inwards.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
1693	...	117,387	...	104,062
1694	...	135,972	...	81,148
1750	...	511,680	...	179,860
1790	...	581,095	...	318,098
1800	...	796,632	...	729,554
1816	3,119	629,050	3,077	618,823
1816-20	4,416	804,481	3,604	681,203
1821-30	4,840	888,431	3,623	726,954
1831-40	5,538	1,017,862	4,630	928,744
1841-50	8,018	1,596,453	5,700	1,124,793
1851-60	10,650	2,627,280	7,746	2,050,432
1861-70	11,249	3,928,069	7,909	2,641,745
1871-80	11,135	5,135,225	8,018	4,020,388
1881	10,765	5,810,043	8,081	4,178,960

Since 1873 vessels with ashes and manure have been included Coasting in the coasting trade, and therefore the figures after that date show trade much greater progress than has actually taken place. In 1750 the number employed was 6396, and in 1795 it was 11,964 of 1,176,400 tons. The following table (XVI.) gives details from 1855:—

	Entered.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
1855	19,040	2,852,223	8,483	878,182
1860	18,365	3,154,561	8,814	1,077,004
1865	14,923	3,065,380	8,035	1,121,864
1870	12,793	2,849,872	9,125	1,208,592
1874	30,828	3,505,449	9,882	1,247,548
1881	56,112	4,290,663	10,470	1,463,716

The following table (XVII.) gives the number of vessels registered in the port of London in various years from 1701:—

Tonnage.	C.	G.M.		Sailing Vessels.		Steam Vessels.		Total.	
				Vessels.	Tonnage.	Vessels.	Tonnage.		
1,812	84,882	10,165	1850	2,719	173,427	338	47,916	3,057	641,848
2,666	97,516	30,869	1860	2,411	680,392	527	189,199	2,938	869,591
4,760	56,242	41,402	1870	2,221	774,631	690	294,066	2,911	1,068,697
	894,627	56,948	1881	1,637	506,865	1,072	611,714	2,709	1,118,579

shipping

**Values of exports and imports.** Declared values of the exports from London have been made at various periods, and are now made annually in the statement of the trade of the United Kingdom. Since 1840 the value has more than quadrupled, being in that year £11,586,037, from which it gradually rose almost without intermission till it was £60,232,118 in 1874, but from that year it declined till in 1879 it was £47,935,753. In 1880 it again rose to £52,600,929, considerably above the average of the four years 1876-79, which was £49,884,673, but as much

below the average of 1872-75, which was £57,144,480. No return of the value of the imports is given before 1872, when they were £124,174,141. The value for 1880, £141,442,907, exceeds that of any previous year, the next being that for 1877, £140,332,773, while the average for 1872-75 was £129,449,956, and for 1876-79 £132,754,772. The following table (XVIII.) gives details of the principal imports for 1860 and 1880, and also a comparison with the United Kingdom in regard to the same articles:

Principal Articles.	1860.			1880.

**Docks.** In the time of Stow, Billingsgate had begun to supersede Queenhithe as the principal landing place of the port of London; but he also gives a list of other "common watergates," and mentions that there were besides "divers private wharfs and keys all along from the east to the west end of the city, where merchants of all nations had landing places, warehouses, cellars, and stowage of their goods and merchandises." On account, however, of the attempts made to avoid the payment of customs by the use of private landing places, a royal proclamation of Elizabeth appointed certain quays to be used as general landing places and others for special purposes. After the great fire the limits of the port were declared to be the North Foreland and London Bridge; certain wharves named "legal quays" were appointed for the general trade, and others named "suffrance wharves" were permitted to be used under certain conditions with the special leave of the commissioners. The frontage of the legal quays in 1795 was only 1419 feet, and of the suffrance quays about 3600 feet, and so inadequate was the storage accommodation that it would not have sufficed even for the single article of sugar. After the proposal for the establishment of wet docks was made by the West India Company the system was very rapidly extended. The West India docks at the Isle of Dogs were opened in 1802, the London docks at Wapping in 1805, the East India docks at Blackwall in 1806, St Katherine's docks to the east of the Tower in 1823, the Victoria docks in 1850, and the Millwall docks at the Isle of Dogs in 1868. The West India Company was granted for twenty years a monopoly of the West India trade, the London Dock Company of the trade in wine, brandy, tobacco, and rice, and the East India Company of the East India and China trade, but in no case were the privileges of the companies renewed. The various docks have at different times undergone improvement and extension to meet modern necessities, the latest addition being the Albert extension of the Victoria dock, opened in 1880, which affords an additional water space of 70 acres, and is unsurpassed in the completeness of its arrangements by any other dock in the world. The St Katherine's, London, and Victoria and Albert docks are now held by one company, and the East and West India docks by another, who are adding to their accommodation by the construction of the Tilbury docks specially for ocean steamers. All the great merchandise docks are thus on the north side of the river,—

the Commercial docks, which date from 1696, and were reconstructed in 1807, and the Surrey docks (1812), on the south side of the river, being used almost exclusively for timber and grain. The position of St Katherine's docks renders it impossible to adapt them to modern requirements; and probably, on account of the increased use of large ocean steamers, all the older docks may soon be superseded as regards the bulk of the foreign trade. The water area of the docks on the north side of the river, which in 1861 was 272 acres, will soon be 465 acres. The Surrey and Commercial dock, which is very complicated in its construction, has a total area, including land and water, of 330 acres. The land and water area (in acres) of the several docks on the north side of the river at present completed or in process of construction is as follows (Table XIX.):

Docks.	London.	St Katherine's.	West India.	Victoria and Albert.	Millwall.	Tilbury.	Total.
Water.....	40	10	136	173			465
Land.....	59	13	210	460			1,472
Total.....	99		346				

The bonded warehouse system was sanctioned in the port of London in 1803, and the exclusive enjoyment for several years of this privilege gave it a great advantage over the other ports of the kingdom. The warehouses of the dock companies, each occupied with their special class of goods, embrace a large portion of the City area, but the rapidity with which goods now pass into consumption renders this kind of dock property at present very unprofitable, and it is probable that very soon many of the warehouses will be turned to other uses.

The Custom-House in Lower Thames Street was built by Inigo Jones, 1614-17, but on account of the subsidence of the central part the house, present Corinthian façade, 490 feet in length, designed by Smirke, was afterwards added. In the building there is a museum containing various old documents and specimens of articles seized by the custom-house authorities.

Trinity House, Tower Hill, a plain building with an ornamental Tudor façade, erected in 1793 from the designs of Wyatt, is the seat of an association of mariners which received a charter from Henry VIII.

in 1514, and gradually acquired the management of lighthouses and buoys not only on the Thames but on the whole English coast, besides the superintendence of naval arsenals and dockyards. Along with the corporation of the City it had the conservancy of the Thames, until those authorities were superseded by the Thames Conservancy Board. Its general rights and privileges have also been much curtailed since 1853, when it was put under the partial control of the Board of Trade, but it has still the sole charge of the erection and maintenance of lighthouses and buoys, the examination of pilots and of navigating lieutenants: and two of its elder brethren act as nautical advisers in the High Court of Admiralty.

**The City.** The prosperity of that portion of London known as the City is largely due to its proximity to the port, but the rapid development of the trade of the port is closely connected with the increase of London outside the City limits, which is of course dependent on a great variety of causes. The uninterrupted extension of the business and financial transactions of the City, and the connexion of these with the rapid increase of the surrounding population, is sufficiently evidenced by the fact that the rateable annual value of the City has risen from about £760 an acre in 1801 to about £5300 an acre in 1881; that the net profits under the commercial and mercantile schedule D for the combined boroughs of the metropolis (1879-80) amounted to £81,088,368, of which the profits for the City alone amounted to £39,263,424, a larger sum than that of the whole seventeen next largest cities and towns of the United Kingdom; and that the number of persons entering the City daily during the sixteen hours of business has increased from 657,379 in 1866 to 739,640 in 1881.

**Exchanges.** The business centre of London is the Royal Exchange, which occupies a commanding position between Threadneedle Street and Cornhill, at the principal convergence of the City thoroughfares. The first building, erected 1565-70 by Sir Thomas Gresham and presented to the City, was destroyed by the great fire, and the second opened in 1669 was also burnt in 1838. The present exchange (1839-44), designed by Tite and erected at a cost of £180,000, is a quadrangular structure with an imposing Corinthian portico at its principal entrance, and encloses a court surrounded by an ambulatory. It is in the open central area that the commercial transactions take place—the ground floor being occupied by shops and offices, and the principal floor by insurance companies and “Lloyd’s rooms.” The principal exchanges for special articles are the corn exchange in Mark Lane, where the privilege of a fair was originally granted by Edward I.; the wool exchange in Coleman Street; the coal exchange adjoining the custom-house, erected in 1849 in the Italian style, and consisting of a rotunda surmounted by a dome; and the auction mart for landed property in Tokenhouse Yard. The metal market is a very important one; and there is also a very large consignment of precious metals and diamonds, the workers in which are chiefly concentrated in the neighbourhood of Clerkenwell. The Royal Mint, Tower Hill, erected in 1805 on the site of the Cistercian abbey of St Mary, is the only mint in England for the fabrication of gold and silver coins, but bronze coins are chiefly made at Birmingham, and gold coinage is now also manufactured at Sidney and Melbourne.

**Banking.** The unique commercial position of London, and its intercourse with every quarter of the globe, have assisted to make it financially in a more complete sense than it is commercially the metropolis of the world. The stock jobbers and brokers, who according to the City census of 1881 numbered 1682, and who have their offices chiefly in the courts and alleys adjoining the Bank of England and the Royal Exchange, are nearly all members of the stock exchange, for whom the present building in Capel Street was erected in 1801; but there is also an open stock exchange in Lothbury. The earliest approximation to banking transactions in London appeared in the negotiations for loans between Elizabeth and the principal city merchants, but the general adoption of the system was due to the civil war, when the merchants, some of whom had already made use of the Royal Mint as a bank of deposit, and the landed proprietors, began to place their money for the sake of greater security in the hands of the goldsmiths. Some of the private banks now existing, such as Coutts’s and Child’s, date from the 17th century, and a new era in the financial history of London was inaugurated in 1694 by the foundation of the Bank of England, of which a full account is given in the article BANKING (vol. iii. p. 316 sq.). Until 1733 the business of the bank was carried on at Grocers’ Hall. The present building, which covers about 4 acres, and was enlarged in 1770 and 1788 by Sir Robert Taylor and Sir John Soane, presents to the street a low triangular wall without windows, and almost entirely devoid of ornament except at the north-west corner, which was copied from the temple of the Sibyl at Tivoli. Until the establishment of the London and Westminster Bank in 1834, the Bank of England was the only joint-stock bank in London. The private and joint-stock banks which have offices in London now number over 150. The principal banks are members of the Clearing House near Lombard Street, where a daily exchange of drafts or cheques is effected. For the year ending April 30, 1882, the total amount of bills, cheques, &c., paid at the

Clearing House was £6,582,645,000, the largest sum in the fifteen years for which statistics have been collated. The amount for the first year ending 1868 being only £3,257,411,000. The extent of the commercial enterprise of London is strikingly indicated by the large number of companies, with their field of operations chiefly in foreign countries, which have been projected in the City or have in it their headquarters. The foreign operations of these companies are however sometimes only nominal, their real business being wholly confined to London itself.

The largest manufacturing industry in London is that of brewing, the number of common brewers in 1880 being 110, who made use of 9,955,177 bushels of malt, while of the 412,192 barrels of beer exported from the United Kingdom 286,206 were from London. To supply the breweries with water, wells now require to be sunk below the chalk to the greensand. According to Stow, the brewers in 1585 in London and Westminster, who then remained “near to the friendly water of Thames,” numbered 26, some of them being foreigners, who first introduced the art of cultivating hops. Among the oldest and most important of the breweries now existing is that of Barclay, Perkins, & Co., which covers an area of 12 acres, belonged at one time to Johnson’s friend Thrale, and occupies the site of the old Globe theatre.

Silk-weaving, which received a special impulse from the settlement of foreign refugees at Spitalfields after the revocation of the edict of Nantes, has within the last fifty years been in a stagnant condition, owing chiefly to the rivalry of Lancashire. The majority tries of the other manufactures are carried on in the neighbourhood of the Thames. The ships built in London in 1881, which are principally yachts, numbered 64, but their total tonnage was only 2723. The principal shipbuilding yards are at the Isle of Dogs. Boat-building is extensively carried on at Chelsea and at several other places in the upper reaches of the river. There are large engineering-works at Lambeth and Millwall, potteries and glass-works at Lambeth, Whitefriars, and Southwark, tanneries at Bermondsey, chemical-works on the Lea, paper-works on the Wand, and sugar bakeries at Whitechapel. The cabinetmakers’ shops are situated principally in the neighbourhood of Shoreditch, but there are several adjoining Tottenham Court Road and Hampstead Road, where upholstery warehouses are very numerous. Lucifer match making gives employment to a large number of women and children in the eastern districts. There are extensive hat manufactories in Lambeth. The special manufactures in different parts of London are too numerous for mention. The principal depôts of the carriage-builders are in Long Acre. A large trade in second-hand clothing is done by the Jews at Houndsditch, especially on Sunday morning, and on the same day of the week there are bird and fancy animal fairs at Church Street, Bethnal Green, and at St Andrew’s Street, Bloomsbury, near the Seven Dials. The centre of the wholesale book trade is in Paternoster Row, but some of the principal publishers have their premises in the neighbourhood of Covent Garden and still farther west. Fleet Street is largely occupied with the offices of the London and the provincial daily newspapers, but the office of the *Times* is in Printing-house Square. The weekly newspapers have their offices chiefly in streets running off the Strand.

**PAUPERISM.**—London since 1867 has been divided into thirty Poor-law poor-law unions, which are governed by boards of guardians, for unions. the most part elected annually by the householders and owners of property, the number of votes possessed by each owner or householder varying from one to six, according to the value of the property. A proportion of the guardians in each union are *ex officio*, or are nominated by the Local Government Board. The Act of 1867 authorized the establishment of outdoor dispensaries in any union or parish; and in twenty-seven of the thirty unions of the metropolis there are now forty-seven of these dispensaries, the number of prescriptions made up in the year 1880 being over a million. For the maintenance of lunatics and insane poor, of patients suffering from contagious diseases, and of pauper children at school, and for the relief of casual paupers, a metropolitan common poor fund is provided, through the operation of which the cost of maintaining the poor is now equalized, to the extent of 42·3 per cent. of the whole sum applied over the metropolitan area. The good results which have followed, both in lessening expense and diminishing pauperism, especially outdoor pauperism, form a strong argument for the complete equalization of the rates, and the creation of a united poor-law authority for the whole metropolis. The three unions which in 1880 contributed most in aid of the poorer ones were Kensington (£27,708), St George’s (£25,299), and the City of London (£61,080); and the three unions most benefited were Holborn (£21,048), Bethnal Green (£19,835), and St Saviour’s, Southwark (£23,085); but, as will be seen from Table XXI. below, great inequality still exists in the rates, and the rate is generally higher in the poorer districts. Each poor-law union possesses one or more workhouses, but the accommodation is inadequate, and difficulty in dealing satisfactorily with applicants often follows. Several unions, by the powers granted them under the Act of 1867, have combined into districts to provide infirmaries for the sick and imbecile, there being now only three unions—

Bethnal Green, Hampstead, and Lewisham—whose sick are not treated in establishments under medical supervision. In addition to this, the several unions and parishes are combined into one metropolitan asylums district, with a managing body of sixty members, fifteen of whom are nominated by the Local Government Board. The total number of persons relieved in establishments belonging to the managers of the metropolitan asylums district since the first was opened in 1870 has been more than 1200 in imbecile asylums, nearly 50,000 in hospitals for infectious diseases, and 1875 on board the "Exmouth" training ship, which was established in March 1876. The paupers' schools fall to be noticed under another section (see below, p. 834). The amount of accommodation provided in the various establishments of the unions in July 1870 was 35,093 beds, and in December 1880 it was 53,332 beds. Table XX. gives a summary of the poor rate returns for 1880; Table XXI. the rateable value of the different unions in 1871 and 1881, and the

average pauperism, the amount of adjusted relief, and the rate in the pound for relief in 1880; and Table XXII. various particulars in reference to metropolitan pauperism for 1871 and 1880.

The annual income of the various charitable institutions in London is now over £4,000,000, of which at least three-fourths is spent in London. That of the endowed parochial charities of the City of London in 1865 was £64,500, which by 1881 had increased to £116,960, those of Westminster being in the same years £26,555 and £33,124. The income of the charities of the Livery Companies in 1869 was stated to be £99,027, and now the 1028 charities belonging to the companies have an aggregate income of £185,829, representing a capital value of £4,456,768. The amount spent on education is £65,130, and on doles £108,498. In addition, the charities of the corporation probably possess an annual income of £30,000. The parliamentary commission appointed to inquire into the endowed parochial charities of the City of London and

Westminster in the report of 1880 divides them into two classes,—those that are eleemosynary and those that are ecclesiastical. In regard to the first, it states that it is impossible to effect a satisfactory combination or readjustment of them under existing circumstances, and, in regard to the second, that they are so far liberated by altered circumstances as to require reappropriation to new charitable use.

## Police.

**CRIME.**—The London police district, or "Greater London," is divided into two police jurisdictions, that of the metropolitan police, with an area of 440,919 acres, and that of the City police, with an area of 688 acres. The Metropolitan police force, which superseded the night watch in 1830, owes its existence to a bill introduced by Sir Robert Peel, providing for the establishment of a Metropolitan police under the control of the executive government. In 1839 the old watch was abolished within the City limits and a City police force appointed, which, however, is entirely under the control of the common council. There are two police courts within the City district, viz., Guildhall and Mansion House; and thirteen within the Metropolitan district, viz., Bow Street, Clerkenwell, Great Marlborough Street, Marylebone, Westminster, Lambeth, Southwark, Thames (Stepney), Worship Street, Woolwich, Greenwich, Hammer-smith, and Wandsworth. The headquarters of the Metropolitan police are at Scotland Yard. The expenses of the two City police courts in 1880 were £10,031, and those of the Metropolitan police courts were £59,009, of which £10,527 was defrayed by fines and forfeitures. The Metropolitan police have power to regulate the street traffic, to inspect and license cabs, omnibuses, and other public conveyances, to interfere in abating smoke nuisance, and to inspect common lodging-houses. From 6158 in 1861 the Metropolitan force had in 1880 increased to 10,943, or one to every 430 of the population; the City police force from 628 to 830, or one to every 61 of the population. The increase of the City police force is necessitated wholly by the in-

crease in the number of persons who daily frequent the City, for not only has the night population greatly diminished, but the criminal population has become almost extinct. The number of persons belonging to the criminal classes in the whole police district of the metropolis in 1880 was 2392, or one in 1992 of the population in 1881; the number of known thieves 1885, the number in England being 17,907; the number of indictable offences was 17,835 (of which 1137 occurred in the City), the number in England being 52,427; and the number of apprehensions 5261 (City 612), the number in England being 22,281. Of indictable offences 49 were murders, 6 attempted murders, 443 attempted suicide, 1150 burglaries, 8918 simple larcenies, 1745 larcenies from the person, and 367 utterances of counterfeit coin; 47 bodies of persons found dead and unknown were photographed and not identified. The number of offences determined summarily within the area of the Metropolitan police district was 125,308, or 11.41 to every policeman, the proportion of indictable offences to every policeman being 6.70. The number of offences determined summarily within the City area was 5649, or only 6.70 to every policeman, while the proportion of indictable offences was only .78. The total expense of the Metropolitan police was £1,168,061, or about £106 per man; £451,334 was contributed to the expense from public revenue, and £293,071 was received for special services. The expense of the City police, £90,662 in 1880, is defrayed wholly by rate, and the cost per man is about £109.

The following table (XXIII.) gives details regarding police and crime in the Metropolitan police district since 1871, by which it will be seen that, although compared with the increase of population the total number of apprehensions has diminished, there has of late years been a considerable increase in the number of felonies, and that the amount of property lost by felonies has been increasing very seriously:—

	Total Pol Force.	Apprehensions and Convictions.				Felonies.				Persons Apprehended under Poor Law Acts.	Apprehensions for Drink.	
		Persons Apprehended.	Convicted on Trial.	Summarily Convicted.	Number of Felonies.	Apprehensions for Felony.	First Loss.	Amount Recovered.	Proportion per 1000 of Population.		Persons Apprehended.	Proportion per 1000 of Population.
1871	9,655	71,961	2,655	46,608	16,926	654	£77,328	£19,284	4.444	6,142	34,213	6.388

## Prisons.

The Newgate and Holloway prisons are of Aldermen. Newgate, rebuilt after the riots of 1780, is now no longer used for persons awaiting trial in the Central Court. The City prison, Holloway, which is the house of correction for City prisoners, was erected in 1851 at a cost of nearly £100,000. Brixton, which occupied the site of a royal palace, and was granted to the city as a house of correction by Edward VI., was discontinued in 1864; the old Fleet prison was abolished in 1844, its site being now occupied by the Memorial Hall of the Congregationalists; Horse-monger Lane prison was superseded by Wandsworth prison; and the Marshalsea in Southwark, immortalized by Charles Dickens, had been discontinued long before he wrote. The house of detention for Middlesex is Clerkenwell, and its houses of correction are Coldbath Fields for male prisoners and Westminster for females. Wandsworth is the prison for Surrey. The convict prisons within the metropolitan area are Brixton, Millbank, Pentonville, Wormwood Scrubs, Woking, and Fulham.

## Elementary schools.

**EDUCATION.**—Until the constitution of a School Board for London in 1870, the only special organizations for providing education for the poorer classes in London were the British and Foreign School Society, founded in 1808, and the National Society, founded in 1811. Many of the parish schools became amalgamated with those of the National Society, but the united efforts of these societies, and also of the Church of England, of the different denominations, and of various promiscuous charitable institutions, failed so completely to meet the necessities of the rapidly increasing population, that in 1851 the total number of scholars attending public schools was only 167,298, and that in 1871 the returns of the voluntary schools showed that there was accommodation for only 262,259 children, or 39 per cent. of the estimated population of school age. By October 1881 the School Board had supplied accommodation for 236,024 children, which with that in voluntary schools gives a total number of places sufficient for 502,095 children, in addition to which schools are in the process of erection for upwards of 100,000 more. Up to August 1881, 6838 children were sent to industrial schools at the instance of the board, and the board now possesses three industrial schools under its own management. The total number of children attending workhouse, separate union, and parochial and district schools in 1880 was 35,223, the amount paid to teachers in these schools being £37,110. The total

expenditure of the School Board for the year ending 25th March 1881 was £1,236,360. The amount paid by rating authorities in 1881-82 was £676,579, the rate in the pound being 616d., a less rate than that for 1880-81, which was 623d., but in all probability there may for some years be a slight increase. The average cost of the 3129 teachers in 1880 was £125. The gross cost per child has risen from £2, 4s. 9d. in 1874 to £2, 17s. 1d. in 1881, but there will probably be a considerable diminution when the schools become all fully occupied throughout a whole year. The following table (XXIV.) gives a comparison of cost between the board, schools and other schools of London and of England in 1880:—

	Income per Scholar.		Expenditure per Scholar.	
	School Fees.	Voluntary Contributions.	For Salary.	Total Cost.
Voluntary Sch.	£ s. d.	£ s. d.	£ s. d.	£ s. d.

England.....	0 9	0 18 7	0 15 74	2 1 11

Fitzstephen mentions that in his time the three principal churches Gram- possessed by ancient privilege and dignity celebrated schools, and that other schools were permitted on sufferance. The churches schools referred to are supposed by Stow to have been St Paul's Cathedral, St Peter's at Westminster, and St Saviour's, Bermondsey, in Southwark. The various other priories and religious houses which were afterwards founded had each its school, though of less fame than the earlier ones. On account of the suppression of the alien priories and religious houses by Henry V., Henry VI. in 1445 founded grammar schools at St Martin's-le-Grand, St Mary-le-Bow, St Dunstons in the West, and St Anthony's, and in the following year others in St Andrew's, Holborn, All Hallows the Great, St Peter's, Cornhill, and in the hospital of St Thomas of Acon. The custom of school disputations mentioned by Fitzstephen was continued till the time of Stow, who states that they were restrained on account of the quarrels between the boys of St Paul's and St Anthony's. In his time the principal schools "repairing to these

colleges" were St Paul's, St Peter's (Westminster), St Thomas of Acon, and St Anthony's. The last-named, which commonly presented the best scholars, and at which Sir Thomas More, Lord Chancellor Beath, and Archbishop Whitgift received their education, had, however, latterly greatly decayed. Up to the time of the dissolution of the monasteries education in England had been in the hands of the religious houses, but, though many of the grammar schools in London were then discontinued, several were re-erected and endowed, and others were added in subsequent years. Of these schools there are now existing St Paul's, St Peter's (Westminster), Christ's Hospital (Blue Coat School), Merchant Taylors' School, Charterhouse, Mercers' School, and the City of London School.

St Paul's School, St Paul's Churchyard, was re-established in 1512 by Dean Colot, for the free education of one hundred and fifty-three poor children, and was endowed with lands whose original annual value was £123, 4s. 7½d., but which now yield nearly £6000 yearly. The board of governors consists of thirteen members chosen by the Mercers' Company and nine nominated by the universities. Vacancies on the foundation are filled up by competition, and the school-fee for the scholars is £20. The course of study, which formerly was chiefly classical, is now specially designed to prepare for the army examinations. The site of the school will soon be changed to West Kensington, where grounds to the extent of 16 acres have been purchased.

St Peter's School, Westminster, re-endowed by Queen Elizabeth in 1560, provides for 40 queen's scholars on the foundation; and the school is also attended by about 180 day pupils. Besides six junior exhibitions tenable at school, there are eight exhibitions to Oxford or Cambridge. The management of the school is regulated by the Public Schools' Act of 1868. The school, which is in the Dean's Yard, was formerly the dormitory of the monks of the abbey.

Christ's Hospital (Blue Coat School), Newgate Street, founded by Edward VI. in 1553 on the site of the monastery of Grevfriars, has an annual income of over £80,000, and the number of children on the foundation is about 1180, including 440 at the preparatory school at Hertford, of whom 90 are girls. The school is under the management of a court of governors, to which any one may be admitted on payment of a donation of £500. The education is chiefly commercial, but four boys are annually sent to the universities. The boys still retain their ancient dress, as well as several peculiar privileges.

Merchant Taylors' School, which was formerly situated in Suffolk Lane, but in 1875 was removed to the Charterhouse, was founded by the Merchant Taylors' Company in 1561, and provides for the education of 500 boys annually on payment of 12 guineas in the lower school, and 16 guineas in the upper. The site of the present building was purchased for about £90,000, and the new school-house cost £90,000. The rooms of the pensioners of Charterhouse remain entire, as well as the chapel of the date 1512, the master's lodge, and the great chamber, the interior of which is a very fine specimen of Elizabethan work.

Charterhouse, formerly a Carthusian monastery and afterwards the seat of the Howards, was purchased by Sir Thomas Sutton, and in 1611 endowed as a school. On the foundation 80 pensioners are maintained at Charterhouse, and 60 scholars at the school at Godalming, where it was removed in 1872.

The Mercers' Grammar School, Collegiate Hill, Dowgate, was originally attached to the hospital of St Thomas of Acon, which was sold in 1523 to the Mercers' Company on condition that they maintained the school. Of the 180 scholars 25 are free.

For the City of London School, founded by the City corporation in 1635, at Milk Street, Cheapside, to supply education to sons of respectable persons, a new building is in course of erection on the Thames embankment. There are preparatory schools in connexion with University College and King's College.

The University of London, Burlington Gardens, instituted in 1826, and removed in 1869 to its present building in the Italian Renaissance style, is a mere examining body for conferring degrees. University College, Gower Street, founded in 1828 on undenominational principles, supplies instruction in all the branches of education—including engineering and the fine arts—that are taught in universities, with the exception of theology, and is attended by over 1600 students. The buildings, the chief feature of which is the Christianian portico at the main entrance surmounted by a dome, were enlarged by a wing in 1881, and contain a large library, and the Flaxman gallery, with original models by Flaxman. King's College, erected by Smirke in 1828, and forming the east wing of Somerset House, provides similar instruction to University College, but with the addition of theology, and in connexion with the Church of England. At Gresham College, founded in 1597 by Sir Thomas Gresham, and removed to its present building in Basinghall Street in 1844, lectures are given on law, divinity, the sciences, music, and medicine. The lectures of the London Society for the Extension of University Teaching have been instrumental in stimulating to some degree general interest in literary and scientific subjects, and in 1881 were attended by 8000 persons. The legal lectures in

connexion with the Inns of Court are noticed in the article INNS OF COURT, vol. xiii. p. 68 *sq.*

SCIENCE.—The great medical schools owe their fame and success Medical to the attraction which London presents to eminent physicians and schools, surgeons, and to the existence of extensive medical and surgical hospitals, which afford unequalled opportunities for the study of disease. In addition to the university of London, the Royal College of Physicians, founded by Linacre, physician to Henry VII. and Henry VIII., is an examining body for diplomas in medicine; and the Royal College of Surgeons, which originated in the livery company of Barber-Surgeons, formed by the incorporation of the surgeons with the barbers in 1540, has similar authority in regard to the practice of surgery. The College of Physicians, originally located in the private house of Linacre in Knight-Rider Street, and afterwards in a building designed by Wren in Warwick Lane, removed to its present site in Trafalgar Square in 1825, where a Græco-Italian structure was erected from the designs of Smirke at a cost of £30,000. The College of Surgeons, Lincoln's Inn Fields, erected 1835-37 from the designs of Barry at a cost of £40,000, contains the Hunterian Museum, purchased by parliament in 1799 (see HUNTER, vol. xii. p. 390), an extensive library, and a lecture theatre. Until the time of John Hunter the medical and surgical education obtainable in London was of a very unsystematic character, and chiefly of a private nature, the provision made for dissection being often of the meagrest kind, while the lectures on anatomy and surgery were both included in a course of six weeks. Hunter's lectures, first delivered in 1774, had a very influential effect in the development of the medical and surgical schools connected with the hospitals, but their most rapid progress has been during the present century. A full description both of these hospitals and of the hospitals for special diseases will be found in the article ENGLAND, vol. viii. p. 253 *sq.*, and the article HOSPITAL, vol. xii. p. 301 *sq.* Other Among the other scientific schools of London may be mentioned scientific the Royal School of Mines, Jermyn Street; the Normal School of Science, South Kensington; the Royal Veterinary College, Camden Town; the Royal Naval College, Greenwich; the Royal Naval School, New Cross; the Royal Military Academy, Woolwich; and the School of Practical Engineering at the Crystal Palace. The Guilds of London Institute for the advancement of technical education have lately founded colleges at Finsbury and South Kensington. The foundation stone of the South Kensington Institute was laid in 1882, and the building will be opened in 1884, the cost being £75,000, making a total with the Finsbury College of £102,000, in addition to £20,000 for fittings. The amount contributed by the Livery Companies to the undertaking is £23,000.

The most influential of the scientific societies is the Royal Society, Scientific incorporated by Charles II. in 1663. Originally located near Gresham College, Crane Court, it was removed in 1780 to Somerset House, and since 1857 it has occupied rooms in Burlington House, Piccadilly. In 1854 old Burlington House, built by Richard Boyle, earl of Burlington, was purchased by the Government for £140,000, and in 1872 a new building in the Renaissance style was erected for the various societies formerly accommodated in Somerset House, viz., the Chemical Society, the Geological Society (instituted 1807, incorporated 1826), the Society of Antiquaries (1707, 1751), the Royal Astronomical Society (1820, 1831), and the Linnean Society (1788, 1802). The Royal Geographical Society (1830, 1859), occupying a commodious building in Savile Row, has within the last forty years taken a leading part in promoting geographical discovery. The Royal Asiatic Society (1823) is in Albemarle Street. The Royal Institution of Great Britain, in the same street, established in 1799 chiefly for the promotion of research in connexion with the experimental sciences, possesses a large library, a mineralogical museum, a chemical and a physical laboratory, and a foundation for a course of lectures. The Society of Arts, John Street, Adelphi, established in 1754 and incorporated in 1847, for the encouragement of arts, manufactures, and commerce, offers rewards for new inventions and discoveries, and grants certificates and prizes for proficiency in commercial knowledge, the industrial arts, musical theory, and domestic economy. Among other scientific societies the principal are the Statistical, the Meteorological, the Anthropological, the Entomological, the Numismatic, the Zoological, the Botanic, the Horticultural, the Institute of Civil Engineers, and the Royal Institute of British Architects. The Zoological Society, instituted in 1826, rented in 1828 a portion of Regent's Park, where they established gardens which now contain one of the finest collections of live specimens in the world. The gardens of the Botanic Society, which occupy 18 acres of Regent's Park, are not of a strictly scientific character, being used chiefly for musical promenades and flower shows, and are to be distinguished from the Government gardens at Kew, which are noticed under Kew (*q.v.*) The Horticultural Society, founded in 1804, possesses large fruit and flower gardens at Chiswick, and in 1861 entered upon a lease of 22 acres of ground, formerly occupied by the Exhibition of 1851, which they laid out at a cost of £50,000, and where they now hold their flower shows and fêtes.

Of museums, London possesses two on a scale of, unexampled

**Scientific vastness, the British Museum and the South Kensington Museum.** The zoological collection of the British Museum is still at Bloomsbury, but the departments of geology, mineralogy, and botany were removed in 1881 to a new building in Cromwell Road, South Kensington, called the British Museum of Natural History. The British Museum at Bloomsbury, and the South Kensington Museum, which are more directly connected with art than science, are noticed under the section Art. The Museum of Practical Geology, Jermyn Street, occupies a building in the Italian Palazzo style, erected in 1850 by Pennethorne at a cost of £30,000. It was founded in 1835 in connexion with the geological survey of the United Kingdom, and also contains specially fine collections illustrative of the application of the minerals and metals to the useful arts. In the Patent Office Museum at South Kensington there are many of the original examples of the greatest mechanical inventions of modern times; and the United Service Museum, Whitehall, possesses relics and models illustrative both of the art of war and of the great naval and military achievements of England.

**The drama.** DRAMA.—According to Fitzstephen, London, "instead of shows upon theatres and comical pastimes," possessed in his time "holy plays and representations of miracles"; and Stow mentions that in 1391 a play by the parish clerks continued three days together, and that another in the year 1409 lasted eight days, and was "of matter from the creation of the world." In the 15th century the secular began to supersede the sacred drama; its progress in London under Elizabeth and James I. will be touched on below (pp. 846 sq.). After the Restoration the "king's servants" who had previously occupied the Globe and Blackfriars played first at the Red Bull, then in Vere Street, Clare Market, and in 1663 removed to the Theatre Royal in Drury Lane. For Davenant's company, known as the "duke of York's," the Lincoln's Inn theatre was built on an improved plan in 1662, and there for the first time women actors were introduced. The two companies received each special patents in the same year. Before 1672, when Drury Lane theatre was burned, Davenant had removed to a new house built by Wren in Dorset Gardens, at a cost of £2000, and spoken of by Dryden as "like Nero's palace shining all with gold"; and, as the new Drury Lane was far less magnificent in its arrangements, it generally had the worst of the costly competition in which they engaged until the union of the patents in 1682. In 1695 a licence was granted to a new theatre in Lincoln's Inn Fields, and in 1705 Haymarket theatre was opened, chiefly for Italian opera. The Dorset Gardens theatre was demolished in 1709. In 1733 the Lincoln's Inn theatre was removed to Covent Garden. The Act of 1737, which forbade the granting of new licences, gave to the patent houses a monopoly of the legitimate drama till 1813; but in the smaller houses, such as "The Little Haymarket" (erected in 1720), the Goodman's Fields theatre (1727), Sadler's Wells (1764), the Lyceum (1795), the Adelphi (about 1800), the Princess's (1830), the Strand (1831), and St James's (built by Braham, 1835), the law was evaded by the performance of miscellaneous entertainments. The most striking feature in the dramatic entertainments of London is their variety; the old dramatic traditions of England, so closely associated with Drury Lane and Covent Garden, now exercise their influence rather in Germany than in London. London at present possesses about thirty theatres, and the plays of the older dramatists are revived only occasionally, chiefly at Drury Lane, the Lyceum, and the Princess's. Melodrama and the domestic drama win large support, but many theatres rely chiefly on comedy, farce, or operabouffe.

**Musical performances.** MUSIC.—In 1673 the chequered career of English opera in London was first definitely commenced by the performance at Dorset Gardens of *Psyche*, followed by the *Tempest* and a little later *The Prophets* and *King Arthur*. For some time after the opening of the Haymarket theatre, Italian operas were varied by performances of English opera and the spoken drama, but the increasing success of the new entertainment soon led to its exclusive establishment. Since 1847 Italian opera has also been established at Covent Garden. English opera has lately been successfully revived by Carl Rosa, and Italian opera is also threatened with formidable rivalry by the performance on a scale of unexampled grandeur of Wagner's operas in German. The Academy of Ancient Concerts, established in 1710, had the honour in 1732 of introducing to the world that special development of Handel's genius, the oratorio, which still excites a wider and deeper interest in England than any other form of musical composition. The Ancient Concert Society did not find a worthy successor in its special sphere till the establishment of the Sacred Harmonic Society in 1821, which, besides its annual series of performances, formerly in Exeter Hall and latterly in St James's Hall, has organized great triennial festivals at the Crystal Palace. Oratorio performances on a larger scale than those of the Sacred Harmonic are now given at the Royal Albert Hall, but the nature of the building renders them less successful artistically. The Philharmonic Society has since its commencement in 1813 held a leading position in the performance of

great instrumental works, which previous to this had been commenced at subscription concerts conducted by private enterprise, but the orchestral performances at the Crystal Palace are of equal excellence, and of late years the Richter and Halle concerts have excited a larger amount of general interest. The Monday and Saturday popular concerts for chamber music have been the special means of introducing to London audiences instrumental performers of European fame. By the formation of Henry Leslie's choir in 1855, the standard of refinement and taste in unaccompanied part-singing has been improved throughout England, and besides reviving general interest in glees and madrigals, it has been the principal means of giving currency to the "modern part song." The choir, after the suspension of its performances since 1880, was revived in 1882; and there are also in London several local choirs which have attained nearly equal perfection in similar performances. The Bach Society devotes itself to the study and performance of the unaccompanied music of Bach and the older composers. The Concert earliest renderings of the great classical compositions are associated rooms, with the Hanover Square rooms, converted into a club house some years ago, and in a less degree with Willis's rooms, built in 1765, which are now used almost solely for balls and public meetings. The only concert-room in London of a convenient size for important performances is St James's Hall, Regent Street and Piccadilly; for since the purchase of Exeter Hall, associated with the "May meetings," by the Young Men's Christian Association, its use is prohibited even to the Sacred Harmonic Society, and the Royal Albert Hall is much too large for the proper realization of the finer effects either of choral, orchestral, or solo performances. This elliptical building in the Italian Renaissance style, erected from the designs of Captain Fowke, was completed in 1871 at a cost of £200,000, and has accommodation for an audience of about 9000 and an orchestra of 1000. The Crystal and Alexandra Palaces, though they present the additional attractions of fine grounds, of scientific and art exhibitions, and of various forms of out-door amusement, base their claims to support in a great measure on their theatrical and musical performances, and, besides the large central halls for promenades, possess separate concert-rooms. The Crystal Palace, Sydenham, which has a total length of 1608 feet, and a width at the nave of 312 feet, and at the central transepts of 384 feet, was designed by Sir Joseph Paxton, and constructed in 1854, chiefly of iron and glass, out of the materials of the Exhibition building of 1851, at a cost of £1,500,000, including the adornment of the grounds, 200 acres in extent. The Alexandra Palace, Muswell Hill, situated in grounds of 300 acres, was completed in 1875, after having been burned down in 1873. It is built of brick in the form of a parallelogram, covering about 7½ acres, and consists of a central hall 386 feet by 184, two courts on each side 260 feet in length, and a concert-room and theatre detached from the main building. Miscellaneous concerts and other entertainments are given at the Royal Aquarium, Westminster, which was opened in 1876 at a cost of about £200,000.

In London there are probably a larger number of eminent professors of the various branches of music than in any other city of the world, but almost no provision for public musical instruction has been made by the state. The Royal Academy of Music, instituted in 1822, and incorporated by royal charter in 1830, receives from Government only an annual grant of £500, and, though attended by over 400 students, chiefly professional, is hampered in its organization and plans by deficiency in funds. The Guildhall School of Music, in which instruction may be commenced at an earlier stage, was established by the corporation of the City in 1879, and is now attended by 1200 students. The National Training School at South Kensington, for which endowments for only five years were provided, is now discontinued, a proposal having been made to supersede it by a Royal College under the presidency of the Prince of Wales, and with endowments sufficient to afford free education to 50 pupils, as well as maintenance and education to 50 others. The Tonic Sol-Fa College, Plaistow, was incorporated in 1875 for the special purpose of training teachers of music for the elementary schools of the country, that method of instruction in music being now used in the majority of schools where systematic musical instruction is given.

**PAINTING, SCULPTURE, AND THE APPLIED ARTS.**—The most influential and the oldest institution in London connected with painting and sculpture is the Royal Academy of Fine Arts, founded in 1768, which, besides its annual exhibition of art in its new buildings in Burlington Gardens, Burlington House, erected in 1868-69, in the Italian Renaissance style from the designs of Smirke, has also organized classes for art instruction. The Society of Painters in Water-Colours, established in 1804, the Society of British Artists, founded in 1822 and incorporated in 1847, and the Institute of Painters in Water-Colours, hold each an annual exhibition. The National Gallery of Paintings originated in the purchase by parliament in 1824 of the collection of J. J. Angerstein for £57,000. The present Grecian building by Wilkins in Trafalgar Square (1832-38), was enlarged in 1860 and 1869, and in 1876 a new wing was added by Barry at a

cost of over £80,000. The collection has received many additions both by purchase and bequest, and besides many noble examples of the old masters, contains some of the finest pictures of the English school, including the magnificent Turner collection. The National Portrait Gallery, the nucleus of which was formed in 1858, was removed to Exhibition Road, South Kensington, in 1870. In the Grosvenor Gallery, New Bond Street, erected by Sir Connts Lindsay in 1877, there are annual exhibitions of works of art, and occasionally other special exhibitions. Several of the mansions of the nobility contain art galleries, which are open to the public on certain conditions. The most famous of these are perhaps the Grosvenor Gallery in the residence of the duke of Westminster, and the Bridgewater Gallery in the residence of the earl of Ellesmere.

**British Museum.** The British Museum, Bloomsbury, originated in the purchase by Government in 1753 of the collection and library of Sir Hans Sloane, and occupies the site of Montague House. For the reception of the Egyptian antiquities presented by George I. (1801), of the Townley marbles (1805), and of the Elgin marbles (1816), a new wing was added to the building in 1823, but after the presentation of the king's library by George IV. in the same year, it was resolved gradually to reconstruct the whole building, the first portion being finished in 1828, and the work (except the new reading-room) completed in 1852. The exterior of the building is plain, with the exception of the massive Ionic portico at the principal entrance. The contents of the museum are divided into departments, which are under the charge of a keeper and one or more assistant keepers. The departments still at Bloomsbury are those of Printed Books, Manuscripts, Oriental MSS., Zoology, Oriental Antiquities, Greek and Roman Antiquities, Coins and Medals, British and Medieval Antiquities and Ethnography, and Prints and Drawings. The collection both as a whole and in several departments—especially Greek and Roman Antiquities and Engravings—is unequalled in the world, and in all the departments a very high degree of completeness has been attained. For the library and reading-room, see *LIBRARIES*, p. 515.

**South Kensington Museum.** South Kensington Museum, which is under the direction of the Committee of Council on Education, was originated by the late Prince Consort in 1852. The present building, to which the collection was removed from Marlborough House in 1857, is erected of red brick and terra cotta in the Italian Renaissance style, and, though still in process of construction and development, includes a fine range of apartments, the interior consisting of courts and corridors of graceful proportions, and decorated with various designs. It contains a collection of objects of ornamental art, both ancient and modern, as applied to manufactures, a national gallery of British art, in addition to the Foster and Dyce collection, and a fine collection of water-colour paintings, an extensive art library, a collection of sculpture chiefly of the Renaissance period, reproductions of ancient sculptures and paintings, and collections of animal products employed in the arts, of substances used for food, and of materials used for building and construction. Some of the rooms are occupied chiefly by articles on loan. In connexion with the institution there is a National Art Training School, as well as a School of Science and a School of Cookery. The Becham Green Museum, a branch of South Kensington Museum, opened in 1872, besides a permanent food collection, and a collection of animal products, is occupied with various collections on loan. The India Museum, which was removed in 1880 from the India Office to a building in Exhibition Road, South Kensington, and placed under the care of the South Kensington Museum directors, contains a magnificent collection of every variety of Indian art and manufacture. The Soane Museum, Lincoln's Inn Fields, bequeathed to the nation by Sir John Soane in 1837, contains an architectural library, various models of famous ancient buildings, antique sculptures, gems, vases, and bronzes, and several fine paintings. The Royal Architectural Museum, Westminster, founded in 1851, is intended specially to advance the art of architecture by examples of the works of various nations and times, and by courses of lectures, and drawing and modelling classes.

**CLUBS.**—See *CLUBS*, vol. vi. p. 41.

**Churches.** **ECCLESIASTICAL BUILDINGS.**—Fitzstephen states that in his time there were in London and its suburbs thirteen larger conventual churches besides one hundred and twenty-six lesser parochial ones. Stow gives a list of churches existing when he wrote, mentioning those which he knew to be suppressed or united to others. He gives the names of 125 churches, including St Paul's and Westminster Abbey; 89 of these were destroyed by the great fire, and only 45 were rebuilt.

**Paul's.** St Paul's cathedral occupies the site of a church founded in 610 by Ethelbert. After the destruction of the church by fire in 1087, a new edifice in the Norman style was

commenced, which was forty years in building, and according to William of Malmesbury "could contain the utmost conceivable multitude of worshippers." In 1240 a new Pointed Gothic choir was added, and the erection of a lofty tower begun. The work of renovation and adornment was continued until 1315, when the cathedral was declared complete. Its dimensions as given by Stow were as follows:—height of steeple 520 feet; total length of church 720 feet; breadth 130; and height of the body of the church 150 feet. In 1561 the spire was struck by lightning, and the roof of the church partly destroyed by the fire that ensued. From this time it remained in a dilapidated condition until the reign of Charles I.; and the work of restoration under the direction of Inigo Jones, who added to the west front a Corinthian portico, had not been completed when the building was destroyed by the great fire of 1666. St Paul's cross, which stood at the north east corner of the cathedral, was rebuilt by Bishop Kemp in the 15th century, but was removed in 1643, its place being now occupied by a fountain. At the cross great religious disputations were held and papal bulls promulgated, and in its pulpit sermons were preached before the court. The present St Paul's, erected in 1675–97 from the designs of Sir Christopher Wren at a cost of £747,954, is built in the form of a Latin cross, the length being 500 feet, the breadth at the transepts 250 feet, and of the choir and nave 125 feet. The dome, which separates the two transepts and the nave and choir, rises to a height of 365 feet, or of 404 feet to the top of the cross by which it is surmounted, the height of the interior dome being 225 feet. The principal front to the west consists of a double portico of Corinthian pillars flanked by campanile towers 120 feet in height. The transepts are bounded by semicircular rows of Corinthian pillars. St Paul's is remarkable chiefly for its massive simplicity and beautiful proportions. The interior is imposing from its vastness, but the designs of Wren for its decoration were never carried out. Some of the monuments of the old building are preserved in the crypt, where are also the tombs of Sir Joshua Reynolds, Dr Samuel Johnson, J. M. W. Turner, Lord Nelson, the duke of Wellington, and other distinguished men, especially admirals and generals.

Westminster Abbey, as the coronation church of the West-sovereigns of England from the time of Harold, and on account of its proximity to the seat of English government, has acquired a fame and importance which in a certain sense outvie those of St Paul's. It occupies the site of a chapel built by Siebert, in honour of St Peter, on a slightly elevated spot rising from the marshy ground bordering the Thames. A church of greater pretensions was erected by King Edward about 980; but, this church being partly demolished by the Danes, Edward the Confessor founded within the precincts of his palace an abbey and church in the Norman style, which was completed in 1065, and of which there now only remain the pyx house to the south of the abbey, the substructure of the dormitory, and the south side of the cloisters. The rebuilding of the church was commenced by Henry III. in 1220, who erected the choir and transepts, and also a lady chapel, which was removed to make way for the chapel of Henry VII. The building was practically completed by Edward I., but the greater part of the nave in the Transition style, and various other improvements, were added down to the time of Henry VII., including the west end of the nave, the deanery, portions of the cloisters, and the Jerusalem chamber; while the two towers at the west end were erected by Wren, who had no proper appreciation of Gothic. The length of the church, including Henry VII.'s chapel, is 531 feet, or, excluding it, 416 feet, the breadth of the transept 203 feet, the height of the church 102 feet, and of the towers 225 feet. The choir, where the coronation of

Poli.

English sovereigns takes place, is a fine specimen of Early English, with decorations added in the 14th century, and contains among other tombs those of Siebert, king of the East Saxons, Anne of Cleves, and Edmund Crouchback, earl of Leicester. The north transept is occupied principally with monuments of warriors and statesmen, and in the south transept the "poet's corner" contains memorials of most of the great English writers from Chaucer to Thackeray and Dickens. The nave, with its clustered columns, its beautiful triforium, and its lofty and finely proportioned roof, is the most impressive portion of the interior. The monuments in its north and south aisles are of a very miscellaneous character, and commemorate musicians, men of science, travellers, patriots, and adventurers. The monuments in the chapels of St Benedict, St Edmund, St Nicholas, St Paul, St Erasmus, St John the Baptist, and the Abbot Islip are chiefly to ecclesiastics and members of the nobility. Henry VII.'s chapel, which is remarkable for the fretted vault work of the roof, with its magical fan tracery, contains besides the monument of Henry VII. the tombs of many English sovereigns and their children, and also of various other personages of historic fame. In the chapel of Edward the Confessor are the shrine of Edward the Confessor in Purbeck marble, the altar tomb of Edward I., the coronation chairs of the English sovereigns, and the stone of Scone, the old coronation seat of the Scottish kings. In the chapter-house (1250) the meetings of the Commons took place before they were transferred to St Stephen's Chapel; and in the Jerusalem chamber (1376-86), where Edward V. is said to have been born and Henry IV. was brought to die, the sittings of the lower house of convocation of the province of Canterbury are now held.

**Conventual churches of time of Fitzstephen.** Among the conventual churches existing in the time of Fitzstephen, there were destroyed by the fire three, those of St Thomas of Acon, St John the Baptist, and St Martin-le-Grand, founded in 700. Of the other churches there still remain the choir, part of the nave, and portions of the transepts of the old church of St Bartholomew the Great dating from the foundation of the monastery by Rahere, minstrel to Henry I., included in the present church, restored 1865-69, which also contains the tomb of its founder; a pointed pier of the old church of St Catherine Cree, which was the conventual church of St Austin's priory of the Holy Trinity, founded in 1108, but was rebuilt by Inigo Jones; the vaults and some of the old monuments of the old church of St James's, Clerkenwell, built in connexion with the Benedictine nunnery 1100, and replaced by the present structure 1788-92; the east wall and Norman crypt of the building which in the 15th century replaced the old church of the priory of St John's of Jerusalem, Clerkenwell, founded in 1100, and of which the south gate in the Perpendicular style, built in 1504, still remains; and the Temple church, noticed in the article INNS OF COURT. Of the ancient church of St Saviour's, Southwark, belonging to the priory of St Mary Overy, a few seemingly Anglo-Saxon portions were incorporated in the building in the Early English style erected in the 13th century, which has been much disfigured by reconstructions and additions, although the beautiful choir, lady chapel, and transepts remain almost entire. The church of St Katherine's Hospital was removed in 1825 to make way for St Katherine's docks.

**Other old churches.** Of the other churches which escaped the fire the principal are the Chapel Royal, Savoy, rebuilt by Henry VII. on the site of Savoy Palace in connexion with the hospital of St John the Baptist, from 1564 till 1717 used as the parish church of St Mary-le-Strand, constituted a chapel royal in 1773, and restored in 1865 by Smirke after partial destruction by fire; All Hallows, Barking, founded in connexion with the Benedictine convent of Barking, Essex, some time before Richard I., chiefly Perpendicular, and containing several brasses; St Andrew's Undershaft (1520-32), in the Perpendicular style, with a turreted tower, and containing among other tombs that of Stow the chronicler; St Giles's, Cripple-gate, founded 1090, rebuilt in the Gothic style after destruction by fire in 1545 (with the exception of the fine tower, added in 1660), where Cromwell was married, and Milton and Fox the martyrologist were buried; St Helen's, Bishopsgate Street, founded in connexion with a priory of nuns (1216), chiefly in the Third Pointed style, and containing many brasses and monuments of city dignitaries; St Margaret's, Westminster, founded by Edward the Confessor,

re-erected by Edward I., and frequently restored, containing a window originally executed by Gouda for Waltham Abbey, and possessing a large number of monuments to eminent persons; St Olave's, Hart Street, in the Gothic style, belonging to the 14th century, but much altered by restoration, containing a large number of brasses and monuments; the small church of Trinity in the Minories, formerly connected with a convent founded by Blanche, wife of Edmund Plantagenet, second son of Henry III., containing in a state of complete preservation the head of the duke of Suffolk, father of Lady Jane Grey.

That the only important external feature of Wren's churches is Wren's the tower or steeple is a peculiarity to be explained by the fact that the merit of his style consisted more in beauty of general outline than in elaboration of details, that from the amount of money placed at his disposal he was generally compelled to concentrate his chief attention on a special part of the building; and that on account of the crowding of surrounding buildings the steeple was often the only part of the church that could be made effective. His interiors, however, are finely proportioned. Among his more important churches are St Bride's, Fleet Street, which possesses one of his finest steeples, and contains the grave of Richardson the novelist; St Dunstan-in-the-East, of which the only portion by Wren now remaining is the steeple, resting on quadrangular columns with a mural crown copied from St Nicholas's, Newcastle; St James's, Piccadilly, only remarkable for its elaborate interior and a white marble font by Gibbons; St Lawrence, Jewry; St Mary-le-Bow, containing the Norman crypt of the old building, which was the first church in the city built on arches (hence the name), and adorned with one of the finest of Wren's steeples, in which are the proverbial "Bow Bells"; St Michael's, Cornhill, with Perpendicular tower imitated from that of Magdalen College, Oxford; St Mary, Aldermary, rebuilt by Wren on the Gothic model of the old church; St Stephen's, Walbrook, with an interior similar to St Paul's; St Swithin's, Cannon Street, in a wall of which the famous "London Stone" is built; and St Clement Danes, in which Dr Samuel Johnson was accustomed to worship.

Of the churches of the period succeeding that of Wren, the most later notable are St George's, Hanover Square (1724), by James, with church. Classic portico and tower, and three painted windows of the 16th century made at Mechlin; St Giles-in-the-Fields (1734), by Flitcroft, with tapering spire, and containing the graves of Flaxman the sculptor and Andrew Marvel; St Martin-in-the-Fields (1726), by Gibbs, with a fine Corinthian portico, behind which the spire is awkwardly placed; St Mary-le-Strand (1717), by Gibbs, occupying the site of the old Maypole; St Mary-le-Bone (1817), by Hardwicke, in the Classic style, containing altarpieces presented by Wren to the old church; St Pancras (1822), with a steeple in imitation of the Temple of the Winds, and a very elaborate interior copied from the Erechtheum at Athens; St Paul's, Covent Garden, originally designed by Inigo Jones, and restored after a fire in 1795. The more modern churches are chiefly in the Gothic style.

Of the religious buildings connected with the numerous denominations and nationalities, few possess exceptional interest either of churches as an antiquarian or architectural character. St George's Cathedral, and Southwark (1848), designed by Pugin, is said to be the largest chapel. Roman Catholic building erected in England since the Reformation; and Ely Chapel, Holborn, the only remaining relic of the palace of the bishops of Ely, has lately been purchased and restored by the Roman Catholics. Among the chapels belonging to the Protestant dissenters the best known are perhaps Mr Spurgeon's Tabernacle, the City Temple, and Christ Church, Newington. The Dutch Church in Austinfriars was presented by Edward VI. to Dutch residents in London in 1550; the nave is in the Decorated style of the 13th century.

Lambeth Palace, situated near one of the old hithes or landing places of the Thames, came into the possession of the archbishops of Canterbury in 1197. The oldest portion of the present building, including the chapel in the Early English style, was erected by Archbishop Boniface (1244-70), but the Lollards' Tower, in which the Lollards were tortured and the earl of Essex was imprisoned, was built in 1434, and the great hall with an elaborate timber roof in 1663. The inhabited portion was erected 1828-48, from the designs of Blore. The adjoining church of St Mary, the oldest part of which dates from the 14th century, contains the tombs of several archbishops, as does also the palace chapel. The library is noticed in LIBRARIES, p. 516.

**ROYAL PALACES AND GOVERNMENT BUILDINGS.**—Stow mentions that in his time there was a large building called the Old Wardrobe in the Old Jewry, very ancient, but of which all that he knew was that it had been alluded to by Henry VI. as his principal palace in the Old Jewry. The palace of Westminster existed at least as early as the reign of Canute, but the building spoken of by Fitzstephen as an "incomparable structure furnished with a thousand

and a bastion" is supposed to have been founded by Edward the Confessor, who built what was afterwards known as the Painted Chamber, and also the apartment afterwards used by the House of Lords. The palace was probably enlarged by William the Conqueror, and William Rufus built the great hall in 1097. The palace suffered severely from fire in 1263 and 1299, and after the great fire of 1512 it was no longer used as a royal residence, and was allowed for a time to fall into decay, with the exception of the great hall. Subsequently it was fitted up and made use of for the meetings of parliament until 1835, when again the whole, with the exception of the great hall, fell a prey to the flames. The apartment in which the House of Commons met was the beautiful St Stephen's chapel, originally built by Stephen. Westminster Hall, which is 290 feet long, 68 feet wide, and 90 feet in height, with a carved timber roof remarkable for its beauty and the ingenuity of its construction, is used as the vestibule of the law courts and the Houses of Parliament. According to Stow the "princes" after the destruction of Westminster Palace "lodged in other places about the city, as at Baynarde's castle (which was destroyed in the great fire), at Bridewell, and Whitehall, sometime called York Place, and sometime at St James's." It was at Bridewell, which occupies the site of an old Norman tower, and was for a long time the occasional residence of the kings of England, that Henry VIII., who, according to Stow, built there "a stately and beautiful house of new," was staying, on account of the destruction of Westminster Palace, when the interview took place in 1528 between him and his nobles, commemorated in the third act of Shakespeare's *Henry VIII.* After the fall of Wolsey, York House, which from 1248 had been the residence of the archbishops of York, came into the possession of the crown, and obtained the name of Whitehall. The palace was almost reconstructed by Henry VIII., who made it his principal residence, and employed Holbein in its decoration: but a new banqueting hall, erected by James I. in place of the old one burned down in 1615, was the only portion of the building which escaped the destruction caused by fire in 1691 and 1697. This hall, converted into a royal chapel by George I., is a fine specimen of Palladian architecture, and its ceiling is adorned with allegorical paintings by Rubens. Through the banqueting hall Charles I. passed on his way to execution beneath its windows, and Cromwell breathed his last within an apartment of the palace.

St James's Palace, which after the destruction of Whitehall continued to be the principal royal residence until it was nearly all destroyed by fire in 1809, with the exception of the old gateway, the chapel adjoining, and the presence chamber, was built by Henry VIII. for a country residence instead of Kennington, on the site of an old hospital for lepers founded in the 12th century.

Buckingham Palace, the town residence of Queen Victoria, occupies the site of Buckingham House, purchased by George III. in 1761. The present building in the Classic style was erected 1825-35 by Nash, a west wing with a dull façade 460 feet in length, facing St James's Park, being added in 1846, and a large ball-room in 1856. The picture gallery contains a specially fine collection of pictures by the great Dutch masters.

Kensington Palace, a favourite residence of several English sovereigns, is noticed under KENSINGTON. Marlborough House, built by the first duke of Marlborough in 1710 from the designs of Wren, came into the possession of the crown in 1817, and has been occupied by the Prince of Wales since 1863.

The Tower of London, to the east of the city on the left bank of the Thames, called by Fitzstephen the Palatine Tower, was, according to tradition, originally built by

Julius Caesar, but the nucleus of the present building was begun in 1078 by William the Conqueror, who erected the part now known as the White Tower to take the place of a portion of the walls and towers of the city which had been washed away by the Thames. This tower was completed in 1098 by William Rufus, who also began the St Thomas Tower and the Traitor's Gate. Additions were made at various periods, especially by Henry III., who used it frequently as a residence; and it now occupies an area of 13 acres surrounded by a moat, constructed in 1190, enclosing a double line of fortifications, behind which is a ring of buildings consisting of various towers, and the barracks and military stores, while in the centre is the massive quadrangular White Tower, with Norman arches and windows, and adorned with a turret at each corner. The St John's chapel in this tower is one of the finest and most complete specimens of Norman architecture in England. The Tower of London has an extensive collection of armour, and is the repository for the regalia of England. The execution of the long list of important political prisoners confined in the Tower took place on the neighbouring Tower Hill, and most of them were buried in the chapel of St Peter Ad Vincula.

The new palace of Westminster (1840-67), built at a cost of about £3,000,000 from the designs of Barry, for the Houses of Parliament, Parliament on the site of the old palace destroyed by fire in 1835, is a vast and ornate building in the Tudor-Gothic style, covering altogether an area of about 8 acres. Towards the river it presents a very richly adorned and effective façade. At the north-east corner is the clock-tower, 320 feet in height, resembling the clock-tower at Bruges; above the dome over the central hall a spire rises to the height of 300 feet; and the Victoria tower, 340 feet, surmounts the royal entrance at the south-west corner. The central hall, which is entered by St Stephen's Porch and St Stephen's Hall, built above St Stephen's Crypt, a portion of the old building, separates the House of Peers, which, along with the royal rooms, occupies the western portion of the building, from the House of Commons, to which the eastern portion is assigned.

The Government offices, situated in Whitehall and Downing Street, form several miscellaneous groups erected at different periods and in very various styles of architecture. The Treasury, Whitehall (1737), containing the official residence of the premier, the Education Office, the Privy Council Office, and the Board of Trade, was improved in 1847 by the construction of a new façade designed by Barry. The House Guards, the headquarters of the commander-in-chief, an insignificant building with a central clock-turret, was erected in 1753 on the site of a guard-house built in 1631 for the security of Whitehall. The Admiralty, a plain structure with a Grecian façade, was erected in 1726. The new Public Offices, a fine range of buildings in the Italian style, erected from the designs of Sir Gilbert Scott at a cost of over £500,000, contain the Home, Foreign, Colonial, and Indian Offices, and various other departments. Somerset House, Strand (1776-86), a large quadrangular structure, the finest façade of which is that towards the river, occupies the site of a palace founded by Protector Somerset in 1547. It contains the Exchequer and Audit Office, the Inland Revenue Office, the Office of the Registrar-General, the Admiralty, Register, and the Prerogative Will Office, removed from Doctor's Commons in 1874. The other Government offices at present occupy unpretentious buildings in various streets, chiefly in the neighbourhood of Whitehall and Westminster. Heralds' College (College of Arms), the authority in regard to pedigrees and armorial bearings, is located in Queen Victoria Street, in a building re-erected in 1683 from the designs of Wren. The General Post-Office, St Martin's-le-Grand, City (1825-29), designed by Smirke in the Grecian style, and occupying the site of St Martin's church and abbey, will probably soon be removed further westwards. The General Telegraph Office, opposite the Post-Office, was erected 1870-73 at a cost of £450,000. The new Record Office in the Tudor style (1851-56) is situated in Fetter Lane.

The law courts, which are described in the article ENGLAND, vol. Law viii. p. 261, and were accommodated in Lincoln's Inn and in courts, buildings adjoining Westminster Hall, where they were first established in 1224, will soon be all removed to the New Law Courts in the Strand, designed by Street, and estimated to cost about £500,000.

MEMORIALS AND STATUES.—The principal monuments are The Monument (1671-77), a fluted Doric column designed by Wren, and erected in commemoration of the great fire, at a cost of £13,700; the Nelson Column, Trafalgar Square, by Railton, erected (1843) at a cost of £46,000, a copy in granite from the Temple of Mars Ultor,

Whitehall.

St James's Palace.

Buckingham Palace.

The Tower.

145 feet in height, crowned with a statue of Nelson by Barry, and having at its base four colossal bronze lions modelled by Sir Edwin Landseer: the Duke of York Column, Carlton House Terrace (1833), an Ionic pillar 124 feet, designed by Wyatt, surmounted by a bronze statue by Westmacott; Westminster Column, erected to the memory of the old pupils of Westminster school who died in the Russian and Indian wars of 1854-59; the Guards Memorial, Waterloo Place, erected in honour of the foot guards who died in the Crimea; the Albert Memorial, Hyde Park, a highly decorated Gothic structure adorned with numerous reliefs and statues, erected from the designs of Sir Gilbert Scott at a cost of £120,000; Cleopatra's Needle, presented to the Government by Mehmet Ali in 1819, brought from Alexandria in 1878, and erected on the Thames embankment on a pedestal of grey granite. Temple Bar, erected by Sir Christopher Wren (1670-72), was removed in 1877, but its site is at present occupied by an erection surmounted by a gullin.

The following is a list of the principal public statues:—

Name	Site	Sculptor
Achilles.	Hyde Park.	Westmacott.
Anne, Queen.	St Paul's Churchyard.	Bird.
Brounfeld, Earl of.	Parliament Square.	Raeb.
Bonfield, John, Duke of.	Russell Square.	Westmacott.
Bontwick, Lord George.	Cavendish Square.	Campbell.
Burgoyne.	Waterloo Place.	Boehm.
Canning, George.	New Palace Yard.	Westmacott.
Charles I.	Charing Cross.	Le Sueur.
Charles II.	Chelsea Hospital.	Gibbons.
Clevedon, Lord.	Waterloo Place.	Marochetti.
Cobden.	Hampstead Road.	Wills.
Cumberland, Duke of.	Cavendish Square.	Chew.
Derby, Earl of.	Parliament Square.	Noble.
Lox, Charles James.	Boomsbury Square.	Westmacott.
Franklin, Sir John.	Waterloo Place.	Noble.
George III.	Somerset House.	Bacon.
Do.	Chancery Street.	M. C. Wyatt.
George IV.	Trafalgar Sq.	Chantrey.
Havlock.	Trafalgar Square.	Behnes.
Herbert, Lord.	Ball Mall.	Foley.
Hill, Rowland.	Royal Exchange.	O. Ford.
Jones II.	Whitehall.	Gibbons.
Jenner.	Kensington Garden.	Marshall.
Kent, Duke of.	Portland Place.	Gahagan.
Mull, J. S.	Victoria Embankment.	Woolner.
Napier, Sir Charles.	Trafalgar Square.	Adams.
Outram, Sir J.	Victoria Embankment.	Noble.
Palmerston, Lord.	Palace Yard.	Woolner.
Peabody, George.	Royal Exchange.	Story.
Peel, Sir Robert.	Chancery.	Behnes.
Pitt, William.	Hanover Square.	Chantrey.
Prince Consort.	Holborn Viaduct.	Bacon.
Richard I.	Old Palace Yard.	Marochetti.
Stowe, Sir H.	Chelsea.	Rysbrack.
Victoria.	Royal Exchange.	Lough.

Do.	Tower Green.	Milnes.
Do.	Royal Exchange.	Chantrey.
William III.	St James's Square.	Bacon.
William IV.	King William Street.	Nixon.

(T. F. H.)

## HISTORY.

BRITISH AND ROMAN (to 449 A.D.). Bishop Stillingfleet, writing of London, stated that after the fullest inquiry he was inclined "to believe it of a Roman foundation, and no older than the time of Claudius" (*Origines Brit.*, 1685, p. 43); and several antiquaries and historians hold the same opinion.<sup>1</sup> Although Geoffrey of Monmouth's vision of a great British city of Troynovant, founded by Brut, a descendant of Æneas, must be relegated to the land of myths, we need not necessarily dispute the existence of a British London. There can be little doubt that the name of London has a Celtic origin, and therefore there is probably a grain of truth in Geoffrey's fanciful description. The place was probably very small, but it must have been chosen for its commanding position on the banks of a fine river, and there may be some truth in the assertion that one Belinus formed a port or haven on the site of the present Billingsgate, although it does not follow that "he also made a gate of wonderful structure," or "over it built a prodigiously large tower" (*Historia*, lib. iii. cap. x.). What a British town was like we learn from Julius Cæsar, who tells us that it "was nothing more than a thick wood, fortified with a ditch and rampart, to serve as a place of retreat against the incursions of their enemies" (*De Bello Gallico*, v. 21). We may therefore imagine a clearing out of the great forest of Middlesex, extending probably from the site of St Paul's Cathedral to that of the Bank of England, with the dwellings of the Britons spread about the high ground looking down upon the Thames. The late Mr Thomas Lewis believed that London had attained its prosperity before the

Romans came, and held that it was probably the capital of Cassivellaunus, which was taken and sacked by Julius Cæsar. Not satisfied with affirming the existence of a British London; he went further, and indicated its extent. On the hill situated between the river Fleet on the west and the Wallbrook on the east was seated the British town. The western gate was Ludgate and the eastern Dowgate, and much of Mr Lewis's argument rests upon the fact that these two names are of British origin (*Archæologia*, vol. xi. p. 59). The origin of London will probably always remain a subject of dispute, for want of decisive facts. A negative fact is that few if any remains of an earlier date than the Roman occupation have been discovered;<sup>2</sup> but, on the other hand, London could scarcely have come to be the important commercial centre described by Tacitus if it had only been founded a few years previously, and after the conquest of Claudius. Now there can be no doubt that the Britons made considerable progress during the period between Julius and Claudius, and it seems upon the whole highly probable that London as a British settlement may have come into existence then. There is some reason to believe that there were two settlements, one on the north and the other on the south bank of the Thames. If so they would be within the territories of distinct and possibly hostile tribes. There might be a ferry, and even, as we shall mention presently, a bridge of some description towards the close of the period, but this point will come before us again.

The Roman occupation of Britain extended over a period equal to that which has elapsed since Henry VIII.'s reign. During these centuries (43-409 A.D.) there was ample time for cities to grow up from small beginnings, to overflow their borders, and to be more than once rebuilt. The earliest Roman London must have been a comparatively small place, but it probably contained a military fort intended to cover the passage of the river. The mouth of the Thames was then only a few miles off, large portions of what are now the counties of Kent and Essex being marshes overflowed with water. The original investigations of Sir Christopher Wren led him to take this view, and he expressed the opinion that "the whole country between Camberwell Hill and the hills of Essex might have been a great frith or sinus of the sea, and much wider near the mouth of the Thames, which made a large plain of sand at low water, through which the river found its way. This mighty broad sand (now good meadow) was restrained by large banks still remaining, and reducing the river into its channel; a great work, of which no history gives account; the Britons were too rude to attempt it, the Saxons too much busied with continual wars; he concluded therefore it was Roman work" (Wren's *Parentalia*, p. 285). The opinion that these embankments are Roman work is the one generally held, but so greatly does opinion vary on all these points that some have supposed that they were not built until the reign of Henry VI.<sup>3</sup> Neither Strabo nor the elder Pliny alludes to London, although they wrote on Britain, and the name does not occur in literature until used by Tacitus. That author distinctly says that London had not in 61 A.D. been dignified with the name of a colony (*Annal.*, xiv. 33). The Roman general Paulinus Suetonius, after marching rapidly from Wales to put down a serious insurrection, found Londinium unfitted for a basis of operations, and therefore left the place to the mercy of Boadicea, who entirely destroyed it and killed the inhabitants in large numbers. When Tacitus wrote, Verulamium and Camulodunum possessed mints, but Londinium was not so distinguished. Subsequently, however, it became a place of mintage. When the British power was finally destroyed London again grew into importance, and we find it holding an important position in the Itinerary of Antoninus, Londinium being either a starting-point or a terminus in nearly half the routes described in the portion devoted to Britain. Ptolemy mentions Londinium, but places it on the south side of the Thames; this may merely be a mistake on Ptolemy's part, but it seems more probable that he referred more particularly to Southwark, which, as has been already pointed out, may have had a distinct origin from the Londinium of the north bank of the river. Londinium was plundered in the reign of Diocletian and Maximian by the army of the usurper

<sup>2</sup> General Pitt Rivers (then Colonel Lane Fox) discovered in 1867 certain piles in excavations near London Wall and Southwark Street, possibly the remains of pile buildings, which he made the subject of a paper read before the Anthropological Society of London (*Journal*, vol. v. pp. lxxi-lxxx). These piles averaged 6 to 8 inches square, others of a smaller size were 4 inches by 3 inches, and one or two were as much as a foot square. They were found in the peat just above the virgin gravel, and with them were found the refuse of kitchen middens, broken pottery, &c., of the Roman period, but there was no superstructure. There is not much here upon which to found a theory, but nevertheless the fact is a valuable item of evidence in a very complicated question. If, as seems certain, these piles are remains of pile dwellings, there is every reason to believe that they were sunk by the Britons rather than by the Romans, and General Rivers thinks it probable that they are the remains of the British capital of Cassivellaunus, situated in the marshes, and of necessity built on piles.

<sup>3</sup> Sir George A. Airy holds that the embankment of the lower reaches of the Thames could not have been undertaken until after the construction of Old London Bridge, as when that was built the tide must have been small (*Proc. Inst. Civ. Eng.*, vol. xlix. p. 120). It is evident that, when the tidal water covered half a mile on both banks of the Thames for a distance of 30 miles, the river proper must have been considerably shallower than at present. Mr J. B. Redman calculated that the quantity of water shut out by the embankments equalled from five-eighths to three-fourths of the present tidal column (*Proc. Inst. Civ. Eng.*, vol. xlix. p. 67).

<sup>1</sup> Dr. Coste affirmed that the notion of a British town having "preceded the Roman era" has no foundation to rest upon, and is inconsistent with all we know of the early geography of this part of Britain (*Archæological Journal*, vol. xviii. p. 140); and Mr J. R. Green in his lately published work, *The Making of England*, expresses the same opinion (p. 101). This was not, however, Mr Kemble's belief, for he held that it was difficult to believe that Cair London was an unimportant place even in Cæsar's day (*Saxons in England*, vol. ii. p. 266).

Allectus, but before the Franks who chiefly formed this army could by Constantius sailed up the Thames and disembarked under the walls of the city, thus taking them by surprise. Under Julian London was the headquarters of Lupicinus in his campaign against the Scots and Picts; and in the reign of Valentinian, Ammianus tells us, Theodosius came to London from Boulogne to mature his plan for the restoration of the tranquillity of the province. It is on this occasion that Ammianus speaks twice of Londinium as an ancient town, to which the title of Augusta had been accorded. By the anonymous chorographer of Ravenna it is called Londinium Augusta. As Theodosius is said to have left Britain in a sound and secure condition, with its dilapidated places restored, it has been supposed that to him was due the wall of the later Londinium. According to old tradition, however, Constantine the Great walled the city at the request of his mother Helena, who was said to be a native of Britain. In spite of these various references we should know very little of Roman London if it had not been that a large number of excavations have been made in different parts of the city, which have disclosed a considerable amount of early history.<sup>1</sup> These go to prove that the early city occupied a somewhat small area, for it has been discovered that the site of the Royal Exchange was originally a gravel-pit, and had then become a dirty pond outside the walls used as a receptacle for refuse. Cemeteries also once existed in Cheapside, on the site of St Paul's, close to Newgate, and various other places known to have been included in the later Roman London. As it was illegal in Roman times to bury within the walls, these places must at one time have been extra-mural. Among the large number of important sepulchral remains lately found by Mr Taylor in Newgate Street were several *ossuaria*, or leaden vessels for the reception of the calcined bones of the dead. Little attention had been paid to these objects until Mr Roach Smith specially alluded to them in an article on "Roman Sepulchral Remains discovered near the Minories, London" (*Collectanea Antiqua*, iii. 45-62). Subsequently Mr Smith wrote a very elaborate article on "Roman Leaden Coffins and Ossuaria" (*Ibid.*, vii. 170-201), in which he refers to the wealth of the British mines as one of the chief incentives to the conquest of the country by the Romans, and points out that the large use of the costly metal, lead, "manufactured with such skill and so profusely as to supply not only the inhabitants of the towns, but those of villages and villas, with one of the daily requisites of advanced civilization," proves the prosperity and even luxury of the province. When Sir Christopher Wren was making excavations for his building of Bow Church he sunk about 18 feet deep through made ground, when he came upon "a Roman causeway of rough stone, close and well-rammed, with Roman brick and rubbish at the bottom for a foundation, and all firmly cemented." In consequence of this discovery the great architect came to the conclusion, which was corroborated by other reasons, that the causeway he had found continued for the whole length of the town, and formed the northern boundary—"the breadth then north and south was from the causeway now Cheapside to the river Thames, the extent east and west from Tower Hill to Ludgate, and the principal middle street or Pretorian Way was Watling Street" (*Parentalia*, p. 265).

Although it is generally agreed that this early Roman city was comparatively small, and in form an oblong square (a *Londinium quadratum*), its exact situation must be a matter of conjecture. The late Mr Arthur Taylor marked out a district which should be bounded on the west by the Walbrook, on the east by Billingsgate, and on the south by the elevation of the bank of the Thames, - the northern boundary to be a line drawn below Lombard Street and Cornhill. Cannon Street and East Cheap would pass straight through the centre of this enclosure, with the other streets north and south (*Archæologia*, xxxiii. 101). In corroboration of his views, Mr Taylor lays stress on the fact that no funeral urns have been discovered in the district he has marked out. Mr Roach Smith agrees generally with Mr Taylor, but includes a rather larger area. He writes—"I should be inclined to place the northern wall somewhere along the course of Cornhill and Leadenhall Street; the eastern, in the direction of Billiter Street and Mark Lane; the southern, in the line of Upper and Lower Thames Street; and the western, on the eastern side of Walbrook. This suggested plan will give the form of an irregular square, in about the centre of each side of which may be placed the four main gates corresponding with Bridge Gate, Ludgate, Bishopsgate, and Aldgate" (*Illustr. of Roman London*, p. 14). The late Mr W. H. Black, like his predecessors, takes the Walbrook as a boundary, but, instead of making it the western limit, he makes it the eastern boundary, and places his western *Mile* at Ludgate. Newgate Street and Cheapside form the main thoroughfare of his city (*Archæologia*, xl. 41). Although Mr Black argues his case with ability, his view is open to two principal objections, - (1) it leaves the site of London Bridge outside the enclosure, and (2) cemeteries have been

discovered within the proposed limits. As to the date when the limits of this early London were lost sight of in the larger area of the better known Roman city, we have hardly sufficient data even to hazard a conjecture. There is reason to believe, as already stated, that the site of the Royal Exchange was outside the city until the early part of the 3d century, because coins of Vespasian, Domitian, and Severus have been found among the refuse of the gravel-pit. Mr Roach Smith suggests, however, that as no coins of the period between Domitian and Severus were found it is just possible that the plated denarius of the latter emperor may not have been found in the pit itself, but in the vicinity of the houses which were built over the pit in subsequent years. On the other hand, Sir William Tite, in describing the tessellated pavement found in 1854 on the site of the Excise Office (Bishopsgate Street), expresses the opinion that the finished character of the pavement points to a period of security and wealth, and fixes on the reign of Hadrian (117-138 A.D.), to which the silver coin found on the floor belongs, as the date of its foundation. Of course this is not conclusive, as the pavement might have belonged to a villa outside the walls, but Sir William Tite places it within them. When the line of the walls which continued until the great fire was first planned out it is impossible to say with any certainty. Some antiquaries hold the opinion that these walls were post-Roman; but this is not the view of Mr Roach Smith, one of our greatest authorities. Mr J. E. Prie, after describing "a bastion of London wall" discovered in Canonile Street, Bishopsgate, arrives at "the conclusion that these interesting relics are portions of a Roman sepulchral monument which, falling into decay, became, as years rolled on, a suitable quarry for medieval builders, providing from its position on the spot convenient materials for the erection of a structure requiring such solidity and strength as would a bastion to the city wall." In describing the outline of the Roman city it is impossible to make ourselves intelligible unless we use names adopted subsequently. The line of the wall runs straight from the Tower to Aldgate, where it bends round somewhat to Bishopsgate. It is bordered on the east by the Minories and Houndsditch. One of the finest remaining portions of the old wall was hidden from view a few years ago when some large buildings were erected round it. The line from Bishopsgate ran eastward to St Giles's churchyard, where it turned to the south, as far as Falcon Square, again westerly by Aldersgate under Christ's Hospital towards Giltspur Street, then south by Ludgate, and then down to the Thames. Mr Roach Smith points out that this enclosure gives dimensions far greater than those of any other Roman town in Britain. In 1843 a portion of the old wall was exposed to view in Playhouse Yard, Blackfriars, when a Roman monument erected to a "speculator" of the second legion, named Celsus, was discovered. On the same line further north Sir Christopher Wren, while building St Martin's, Ludgate, found a similar sepulchral monument "in the vallum of the pretorian camp" to the memory of Vivianus Marcellianus, a soldier of the second legion (*Parentalia*, p. 266). In the year 1276 the old wall south of Ludgate was pulled down and a new one built to enclose a larger circuit further west for the benefit of the Black Friars. There appear to be strong reasons for believing that a wall ran along the south, and that the Romans did not consider the river sufficient protection. William Fitzstephen, a monk of the 12th century, who wrote the earliest description of London, mentions the walls and tower in the south, and Sir Christopher Wren also alludes to the colony being walled next the Thames (*Parentalia*, p. 265). The line from Lower Thames Street to Temple Street has been retrieved from the river by embankments, and in certain parts of the line the embankment was formed by substantial walling, such being found at the foot of Fish Street Hill, at the end of Queen Street, and from Broken Wharf to Lambeth Hill (Tite's *Catalogue of Antiquities found in the Excavation at the New Royal Exchange*, 1848, p. xxiv). Mr Roach Smith writes—"It was from 8 to 10 feet thick, and about 8 deep, reckoning the top at 9 feet from the present street level, and composed of ragstone and flint, with alternate layers of red and yellow, plain and curve-edged tiles, cemented by mortar as firm and hard as the tiles, from which it could not be separated. For the foundation strong oaken piles were used, upon which was laid a stratum of chalk and stones, and then a course of hewn sandstones from 3 to 4 feet long, by 2½ in width" (*Archæological Journal*, i. 114). The names of the gates give us no clue as to which of them existed in Roman times, but we cannot doubt that the chief traffic was carried through the city from Ludgate to Aldgate, although some antiquaries have supposed that Newgate was the chief gate on the west side, leading as it would to Holborn, where Roman remains have been discovered. Bishopsgate must have been the principal outlet to the north. Mr Roach Smith has suggested that outside Newgate there was an amphitheatre built into a hill on the rising ground near what was lately the Little Old Bailey. He had often noticed the precipitous descent from Green Arbour Lane opposite Newgate into Seacoal Lane and the level space by Fleet prison, and he presumed it to have been an excavation in the side of the hill. Many a smaller town than Londinium possessed a theatre in Roman times (*Middle-*

<sup>1</sup> A chronological list of the tessellated pavements discovered in London between 1851 and 1864 is given in a paper of the late Sir William Tite (*Archæologia*, vol. xxxix. p. 481). It is impossible to say how much more remains hidden many feet below the modern streets.

*see Arch. Trans.*, i. 33). The name Newgate is significant of its recent erection, and it has been remarked that it stands alone among the gates as not being attached to a ward bearing the same name. It is mentioned in an ordinance of Edward I., where it is connected with Ludgat.

A question arises as to the arrangement of the area included within the walls, the course of which has already been traced. There is a strong preponderance of evidence against the belief that the present line of streets follows that of Roman London to any considerable extent. Sir William Tite gave reasons for believing that Bishopsgate Street was not a Roman thoroughfare (*Archæologia*, xxxvi. 203), and in the late excavations in Leadenhall Mr Loftus Brock found remains of a building which he supposed to be a basilica, apparently crossing the present thoroughfare of Gracechurch Street. Sir William Tite agreed with Dr Stukeley's suggestion that on the site of the Mansion House (formerly Stocks market) stood the Roman forum, and he states that a line drawn from that spot as a centre would pass by the pavements found on the site of the Exchequer Office. Besides the forum, Dr Stukeley suggested the sites of seven other public buildings,—the *Atrium Palatinum*, guarding the south-eastern angle of the city, where the Tower now stands, the grove and temple of Diana on the site of St Paul's, an episcopal residence, &c. No traces of any of these buildings have been found, and they are therefore purely conjectural. As to the temple of Diana, Wren formed an opinion strongly adverse to the old tradition of its existence (*Paræclitic*, p. 265). Although we know that the Christian church was established in Britain during the later period of Roman domination, there is little to be learnt respecting it, and the Bishop Restitutus who is said to have attended a council on the Continent is a somewhat mythical character.

After the walls the most important points for consideration in relation to Roman London are (1) the existence of a bridge, and (2) the purpose of the London Stone.

1. Dion Cassius, who lived in the early part of the 3d century (*Hist. Rom.*, lib. ix. c. 20), states that there was a bridge over the Thames at the time of the invasion of Claudius (43 A.D.), but he places it a little above the mouth of the river ("higher up"). The position is vague, but, as already stated, the mouth of the Thames in these early times may be considered as not far from where London Bridge now stands. Sir George Airy holds that this bridge was not far from the site of London Bridge (*Proceedings of Inst. Civ. Engineers*, xlix. 120), but Dr Guest was not prepared to allow that the Britons were able to construct a bridge over a tidal river such as the Thames, some 300 yards wide, with a difference of level at high and low water of nearly 20 feet. He therefore suggested that the bridge was constructed over the marshy valley of the Lea, probably near Stratford. It needs some temerity to differ from so great an authority as the late Dr Guest, but it does strike one as rather surprising that, having accepted the fact of a bridge made by the Britons, he should deny that these Britons possessed a town or village in the place to which he supposes that Aulus Plautius retired. It may be considered certain that there was no bridge over the Thames in the time of Julius Caesar; for he would not have marched his troops all the way to Coway Stakes in search of a ford if he could have crossed by a bridge at London.

As the Welsh word for "bridge" is "pont," and this was taken directly from the Latin, the inference is almost conclusive that the Britons acquired their knowledge of bridges from the Romans. Looking at the stage of culture which the Britons had probably reached, it would further be a natural inference that there was no such thing as a bridge anywhere in Britain before the Roman occupation; but, if Dion's statement is correct, it may be suggested as a possible explanation that the increased intercourse with Gaul during the hundred years that elapsed between Julius Caesar's raids and Claudius Caesar's invasion may have led to the construction of a bridge of some kind across the Thames at this point, through the influence and under the guidance of Roman traders and engineers. If so, the word "pont" may have been borrowed by the Britons before the commencement of the Roman occupation. Much stronger are the reasons for believing that there was a bridge in Roman times, when remains of Roman villas are found in Southwark, which was at least a portion of Londinium, and it therefore hardly seems likely that a bridge-building people such as the Romans would have been contented with a ferry. Mr Roach Smith is a strong advocate for the bridge, and remarks, "It would naturally be found somewhere in the direct line of road into Kent, which I cannot but think pointed towards the site of Old London Bridge, both from its central situation, from the general absence of the foundations of buildings in the approaches on the northern side, and from discoveries recently made in the Thames on the line of the old bridge" (*Antiquary*, xxix. 160). Mr Smith has, however, still stronger arguments, which he states as follows:—"Throughout the entire line of the old bridge, the bed of the river was found to contain ancient wooden piles; and, when these piles, subsequently to the erection of the new bridge, were pulled up to deepen the channel of the river, many thousands of Roman coins, with abund-

ance of broken Roman tiles and pottery, were discovered, and immediately beneath some of the central piles brass medallions of Aurelius, Faustina, and Commodus. All these remains are indicative of a bridge. The enormous quantities of Roman coins may be accounted for by consideration of the well-known practice of the Romans to make these imperishable monuments subservient towards perpetuating the memory, not only of their conquests, but also of those public works which were the natural result of their successes in remote parts of the world. They may have been deposited either upon the building or repairs of the bridge, as well as upon the accession of a new emperor" (*Archæological Journal*, i. 113).

2. The "London Stone" has very generally been supposed to be a "milliarium" or central point for measuring distances, but Sir Christopher Wren believed it was part of some more considerable monuments in the forum, and his reason for this belief was that "in the adjoining ground on the south side (upon digging for cellars after the great fire) were discovered some tessellated pavements and other extensive remains of Roman workmanship and buildings" (*Parentalia*, pp. 265, 266). King, in his *Munimenta Antiqua*, writes—"London Stone, preserved with such reverential care through so many ages, and now having its top encased within another stone in Cannon Street, was plainly deemed a record of the highest antiquity of some still more important kind; though we are at present unacquainted with the original intent and purport for which it was placed. It is fixed at present close under the south wall of St Swithin's Church, but was formerly a little nearer the channel facing the same place,—which seems to prove its having had some more ancient and peculiar designation than that of having been a Roman milliarium, even if it were ever used for that purpose afterwards. It was fixed deep in the ground, and is mentioned so early as the time of Athelstan, king of the West Saxons, without any particular reference to its having been considered as a Roman milliarium stone." Holinshed (who was followed by Shakespeare in 2 *Henry VI.*, act 4 sc. 6) tells us that when Cade, in 1450, forced his way into London, he first of all proceeded to London Stone, and having struck his sword upon it, said in reference to himself and in explanation of his own action, "Now is Mortimer lord of this city." Mr H. C. Coote, in a paper published in the *Trans. London and Middlesex Arch. Soc.* for 1878, points out that this act meant something to the mob who followed the rebel chief, and was not a piece of foolish acting. Mr G. L. Gomme (*Primitive Folk-Moots*, pp. 155, 156) takes up the matter at this point, and places the tradition implied by Cade's significant action as belonging to times when the London Stone was, as other great stones were, the place where the suitors of an open-air assembly was accustomed to gather together and to legislate for the government of the city. Corroborative facts have been gathered from other parts of the country, and, although more evidence is required, such as we have is strongly in favour of the supposition that the London Stone is a prehistoric monument.

SAXON (449-1066).—At the beginning of the 5th century the Roman legions left Britain. From this period to the arrival of the Saxons there was a space of time when the Briton was left alone, and there is no reason to believe that London ceased to be the important commercial town which it had grown to be. After the Saxon invasion we do not hear of the city being ravaged, and it possibly held its own under the various vicissitudes it had to pass through, although Dr Guest writes that "good reason may be given for the belief that even London itself for a while lay desolate and uninhabited" (*Archæological Journal*, xix. 219). "About 449 or 450 the invaders first settled in Britain, and in 457 Hengist and Æsc fought against the Britons at Crayford, driving them out of Kent. The vanquished fled to London in great terror, and apparently found a shelter there.<sup>1</sup> The Saxons disliked walled towns, and in many instances they destroyed those which they conquered. This was not done in London, and it is just possible that the Britons may have been able to purchase their freedom from destruction. We have, however, little or no data upon which we can form an opinion. Mr Kemble wrote of towns generally that the Saxons neither cared to take possession of them nor took the trouble to destroy them. They enslaved the inhabitants or expelled them, as a mere necessary precaution and preliminary to their own peaceable possession (*Saxons in England*, ii. 296). The only question is whether London, being an exceptional city, had an exceptional fate. Along the banks of the Thames are several small havens whose names have remained to us, such as Rotherhith, Lambhith (Lambeth), Chelchith (Chelsea), and it is not unlikely that the Saxon who would not settle in the city itself associated himself with these small open spots. Places were thus fortified over a large space which otherwise might have remained unsettled. At what time the

<sup>1</sup> If the London-burg here mentioned in the Saxon Chronicle is not London south of the Thames (or Southwark), the fugitives must have crossed the river, and if so this is additional reason for believing that there was then a bridge. The same reasoning will apply to what is related further on, of the Danes crossing to Surrey in the year 861, as it is not likely that a ferry would suffice on these occasions. Moreover, a bridge is shortly after specially mentioned by the chronicler.

Saxons got over their repugnance and settled in London we cannot say, but the city is described by Bede as being in 604 the metropolis of the East Saxons, and an emporium of many peoples who came to it by sea and land. The relics of Roman London are, as we have already seen, very numerous: but we know nothing of the inhabitants. There is little human interest in the history. When we come to Saxon London this position is reversed. There are no remains worthy of notice, but there is abundance of life. London appears to have held a very exceptional position, and to have been somewhat like a German free city. The Londoner within his strong walls defied the invader, and the Dane frequently attempted to conquer the city in vain. Mr Freeman does justice to the stout heart of the Londoner, and calls London during this period "the stronghold of English freedom." The Saxon Chronicle has little to tell of London between the 5th and 9th centuries. The great change accomplished by Augustine, in converting the Jutes and the Saxons to Christianity, is recorded in a few short lines; and we are told that in the year 604 Augustine consecrated two bishops, Mellitus, and Justus, and that Ethelbert, king of Kent, gave Mellitus a bishop's see at London, then a part of the kingdom of the East Saxons, whose king, Siebert, was a tributary of his uncle the king of Kent. What became of the cathedral which we may suppose to have existed in London during the later Roman period we cannot tell, but we may guess that it was destroyed by the heathen Saxons. Bede records that the church of St Paul was built by Ethelbert, and from that time to this a cathedral dedicated to St Paul has stood upon the hill looking down on Ludgate. Mellitus became archbishop of Canterbury, and was succeeded in the see of London by Cadda, who was succeeded by Wina. Then came Theodore, archbishop of Canterbury, better known as the sainted Erkenwald, whose shrine was one of the chief glories of old St Paul's. He died on April 30, 693, a day which was kept in memory in his cathedral by special offices. We must now pass over nearly a century and a half to the time when the Danes were harassing the country after the death of Egbert. The chronicler records that in the year 839 there was a great slaughter at London, but he gives no particulars. In 851 the Danes plundered the city and made themselves masters of it. Sharon Turner quotes a conveyance of a place in London dated 857, which gives a slight piece of local information (*Anglo-Saxons*, ii. 575). The name of the place was Ceolmundingehaga, and it was situated not far from the West Gate. We cannot tell whether Ludgate was meant or some other gate which marked the extent of the liberties on the west. In 871 the chronicler affirms that Alfred fought nine great battles against the Danes in the kingdom south of the Thames, and that the West Saxons made peace with them. In the next year the Danes went from Reading to London, and there took up their winter quarters. Then the Mercians made peace with them. In 886 Alfred overcame the Danes, restored London to its inhabitants, rebuilt its walls, reannexed the city to Mercia, and committed it to Ethelred, alderman of Mercia. Then, as the chronicler writes, "all the Angle race turned to him (Alfred) that were not in bondage of the Danish men." In 896 the Londoners came off victorious in their encounters with the Danes. The king obstructed the river so that the enemy could not bring up their ships, and they therefore abandoned them. The Londoners broke up some, and brought the strongest and best to London. In 912 Ethelred, the alderman of the Mercians, who had been placed in authority by Alfred, died, and Edward the Elder took possession of London and Oxford, "and all the lands which thereto belonged." Again we find a break in the continuity of the history, and pass on to the year 959, when King Edgar gave Dunstan the bishopric of Worcester, and afterwards that of London. In 962 there was a great fever and mortality in London, and St Paul's was burnt. It was, however, founded again in the same year. In the reign of Ethelred II. the Danes were more successful in their operations against London, but the inhabitants resisted stoutly. Snorre the Icelandic tells us that the Danes fortified Southwark with ditch and rampart, which the English assailed in vain. In 982 London was burnt, and in 994 Olaf and Swein (the father of Canute) came with ninety-four ships to besiege it. They tried to set the city on fire, but the townsmen did them more harm than they "ever wened." The chronicler piously adds that "the holy Mother of God on that day manifested her mercy to the townsmen, and delivered them from their foes." The Danes went from the town and ravaged the neighbourhood, so that in the end the king and his witan agreed to give sixteen thousand pounds to be relieved of the presence of the enemy. In the year 1009 the Danes frequently attacked London, but they had no success, and fared ill in their attempts. The Londoners withstood Swein in 1013, but in the end they submitted and gave him hostages. Three years after this, Ethelred died in London, and such of the witan as were there and the townsmen chose Edmund Ironside for king, although the witan outside London had elected Canute. Canute's ships were then at Greenwich on their way to London, where they soon afterwards arrived. The Danes at once set to work to dig a great ditch by Southwark, and then dragged their ships through to the west side of the bridge. They were able after

this to keep the inhabitants from either going in or out of the town. In spite of all this, after fighting obstinately both by land and by water, the Danes had to raise the siege of London, and take the ships to the river Orwell. After a glorious reign of seven months Edmund died in London, and Canute became master of England. The tribute which the townsmen of London had to pay was £10,500, about one-seventh of the amount which was paid by all the rest of the English nation. This shows the growing importance of the town. From this time there appears to have been a permanent Danish settlement in London. There is but little more to be said of the history of Saxon London than that Edward the Confessor held his witanagemot there, and built and consecrated the Abbey of Westminster. During the later part of the Saxon period Westminster (originally Thorney Island) had been growing into some importance. Tradition affirmed that on the site of Westminster Abbey a temple of Apollo once stood, which was destroyed by an earthquake in the reign of the emperor Arcadius. Out of the ruins King Lucius founded a church. 170 A.D. Sir Christopher Wren imagined that the monks, finding that the Londoners pretended to a temple of Diana where St Paul's now stands, did not wish to be behind hand in antiquity (*Pantheon*, p. 296). The fragment respecting King Lucius is of about equal authority. There is more reason for believing that Siebert, king of the East Saxons, may have built, as Stow says he did, "a church to the honour of God and St Peter, on the west side of the city of London." His sons relaxed into idolatry, and left the church to the mercy of the Danes. In a charter of King Edgar, dated 951, the original boundary of Westminster is clearly defined. This charter is marked by Kemble as doubtful (*Codes Dipl.*, dlxi.); but, if not of the date given, it is believed by competent authorities to be of great antiquity. Edward the Confessor took a particular interest in Westminster, and occupied much time in superintending the erection of a new church there. On Childermas Day (December 28) 1065 the monastery was consecrated, and on the following "twelfth mass eve" the king died, being buried on the next day in the new church. The abbot of Westminster's manor is fully described in Domesday, but there is no mention of a palace, so that it has been conjectured that the Confessor lived in the monastery itself. With regard to the buildings of London we are left to conjecture. As several of the Saxon kings lived in the city, we must conclude that they possessed a palace of some kind, and around this other buildings would arise. A port such as London naturally drew foreigners from all parts, and various communities of these strangers are believed to have settled here as early as the 8th century. With regard to the government of the city it is generally supposed that many of its institutions are due to Alfred the Great, although Mr Gade with great ingenuity traces them back to the ordinances of the Roman *municipium*. The famous dooms of the city of London (Athelstan) are stated in the preamble to be the ordinance of "the bishops and the reeves belonging to London." William the Conqueror's charter, which he granted soon after his accession, is addressed to William the bishop and Godfrey the portreeve. The office of portreeve had then been long established, although we know but little of its origin. It was usually an office of popular election, but the king often interfered in the appointment. Considerably more than a century had elapsed after the Conquest before the title of portreeve gave way to that of mayor, as the designation of the chief officer of the city of London.

NORMAN (1066-1154). -- After the battle of Hastings certain of the defeated chiefs retired upon London and urged the men in power to resist the Norman, and set up Edgar Atheling as king, which, as the Saxon chronicler says, "was indeed his natural right." On hearing of this action William marched towards London, and was attacked by the Saxon party at Southwark, who were repulsed by the Norman horse, but with such loss to the latter that William thought it imprudent to lay siege to the city at that time. The Londoners began now to see the hopelessness of their cause, and Archbishop Eldred, and Edgar, and Earls Edwin and Morkere, and "the best men of London" repaired to Berkhamstead, where they submitted themselves and swore fealty to the Conqueror. One of the earliest acts of the Conqueror was to commence the erection of a citadel which should overawe the citizens and give him the command of the city. Some writers have supposed that King Alfred erected a palace or castle on the site of the Tower, but without sufficient authority, and a writer in the *Quarterly Review* (art. "Middlesex," vol. cl. p. 48 note) says, "the Tower almost certainly stands on foreshore which was not dry land before the Conquest." As the Tower was situated at the eastern limit of the city, so not far from the western extremity was built a strong fortification called Baynard's Castle after its founder Baynard, one of the followers of the Conqueror. In the second year of his reign William granted the remarkable charter written in Anglo-Saxon which still exists among the archives of the city of London. There are but four lines and a quarter, and the size of the slip of parchment is only 6 inches by 1 inch. It runs thus: "William the king greets William the bishop, Godfrey the portreeve, and all the burgesses within London, both French and English. And I grant that

they be all law-worth, as they were in Edward the king's days. And I will that each child be his father's heir after his father's days. And I will not suffer that any man do you wrong, God keep you." William Stigand, the bishop of London, was a Norman, and possibly had some influence with the king in obtaining this charter. A wonderful improvement in the appearance of the cities of the country almost immediately followed the advent of the civilizing Norman. Within a few years the whole area of London must have been changed, and handsome buildings arose as if by magic in all parts of the city. Many Normans had settled in London during the reign of Edward the Confessor, but after the Conquest they swarmed in and naturally became the dominant party. In August 1077 occurred a most extensive fire, such a one, says the Chronicle, as "never was before since London was founded." This constant burning of large portions of the city is a marked feature of its early history, and we must remember that, although stone buildings were rising on all sides, these were churches, monasteries, and other public edifices; the ordinary houses remained as before, small wooden structures. The White Tower, the famous keep of the Tower of London, was commenced by Gundulph, bishop of Rochester, about the year 1078. In 1083 the old cathedral of St Paul's was commenced on the site of the church which Ethelbert is said to have founded in 610. But four years afterwards the chronicler tells us "the holy monastery of St Paul, the episcopal see of London, was burnt, and many other monasteries, and the greatest and fairest part of the whole city." In this same year (1087) William the Conqueror died. In 1090 a tremendous hurricane passed over London, and blew down six hundred houses and many churches. The Tower was injured, and a portion of the roof of the church of St Mary-le-Bow, Cheapside, was carried off and fell some distance away, being forced into the ground as much as 20 feet, a proof of the badness of the thoroughfares as well as of the force of the wind. William Rufus inherited from his father a love for building, and in the year 1097 he exacted large sums of money from his subjects with the object of carrying on some of the undertakings he had in hand. These were the walling round of the Tower, the rebuilding of London Bridge, which had been almost destroyed by a flood, and the erection of the great work with which his name is most generally associated, Westminster Hall. In 1100 Rufus was slain, and Henry I. was crowned in London. This king granted to the citizens their first real charter, in which he promised to observe the laws of the Confessor and to redress many special grievances; but he paid little attention to his engagements, and constantly violated the articles of his charter. When Stephen seized the crown on the death of Henry I., he tried successfully to obtain the support of the people of London. He published a charter confirming in general terms the one granted by Henry, and commanding that the good laws of Edward the Confessor should be observed. The citizens, however, did not obtain their rights without paying for them, and in the year 1139 they paid Stephen one hundred marks of silver to enable them to choose their own sheriffs. In this reign the all-powerfulness of the Londoners is brought very prominently forward. Stephen became by the shifting fortune of war a prisoner, and the empress Matilda might, if she had had the wisdom to favour the citizens, have held the throne, which was hers by right of birth. She, however, made them her enemies by delivering up the office of justiciary of London and the sheriffwick to her partisan Geoffrey, earl of Essex, and attempting to reduce the citizens to the enslaved condition of the rest of the country. This made her influential enemies, who soon afterwards replaced Stephen upon the throne. The Norman era closes with the death of Stephen, 1154.

We have already alluded to the great number of ecclesiastical foundations which marked the Norman period, and will here note some of the chief of these, to show how completely the new buildings must have changed the whole appearance of London, and raised it from a mean congregation of houses to the rank of a city, having features of considerable architectural merit. The college of St Martin-le-Grand within Aldersgate was founded in the year 1056, and its rights were confirmed by the Conqueror in the second year of his reign. He gave the dean and secular priests more land, and added to their privileges. A nunnery of the Benedictine order, dedicated to St Leonard, near Bromley, was founded in the reign of William the Conqueror by William, bishop of London, for a prioress and nine nuns, and in Stephen's reign Sir William Mounifitchet founded an abbey at Stratford Langton, which was subsequently known as West Ham Priory. In 1082 a convent of monks dedicated to St Saviour was founded at Bermondsey by Alwin Child, a wealthy citizen, and seven years afterwards some Cluniac monks came from France and settled in the new convent, of which one of them was chosen the first prior. In 1094 William Rufus added the manor of Bermondsey to the other benefactions of this fortunate monastery, which became very powerful, and was frequently used as a royal residence. At Clerkenwell two religious houses were established in the year 1100, viz., the Knights Hospitallars of St John of Jerusalem and the priory of St Mary for nuns of the Benedictine order. It was said that the number of monasteries built in the reign of Henry I. was so great that almost all the labourers became

bricklayers and carpenters, and there was some discontent in consequence. Matilda or Maul, the wife of Henry I., was much interested in the foundation of these religious houses. She established the priory of Holy Trinity, called Christ Church, which was situated to the north of Aldgate, in 1108, and about 1110 two hospitals, one for lepers at St Giles's-in-the-Fields, and the other for cripples at Cripplegate. The priory of St Bartholomew was founded a few years earlier, and the Benedictine nunnery of St John the Baptist at Halliwell near Shoreditch soon afterwards. The Knights Templars made their first habitation in the neighbourhood of London in 1118, and did not remove from Holborn to Fleet Street until nearly seventy years afterwards. The royal hospital of St Katherine's at the Tower was originally founded by Matilda, wife of King Stephen, and the famous St Stephen's chapel at Westminster owes its origin to the king himself. It was, however, rebuilt by Edward II. It will be seen from the above list that a large proportion of these buildings were outside the walls, and this shows how extensive the outskirts of the city had become in Norman times. No doubt many of these religious persons sought out somewhat quiet neighbourhoods, but around each of them would naturally grow up villages formed by those who were chiefly dependent upon the monks and nuns.

PLANTAGENET (1154-1486).—Henry II. appears to have been to a certain extent prejudiced against the citizens of London on account of their attitude towards his mother, and he treated them with some severity. On several occasions he exacted large sums from the city, which, although they were euphemistically styled *dona*, cannot be considered as free gifts. The severity appears to have been necessary, and was attended with good results. The streets were in a most dangerous condition at night, and bands of a hundred and more would sally forth to rob the houses of the wealthy. In 1176 some of these men were taken prisoners, and one of them was found to be a citizen of good credit and considerable wealth named "John the Olde." He offered the king five hundred marks for his life, but Henry was inflexible, and after the man had been hanged the city became more quiet. In 1176 the rebuilding of London Bridge with stone was commenced by Peter of Colechurch. This was the bridge which after much subsequent tinkering was pulled down early in the present century. It consisted of twenty stone arches and a drawbridge. There was a gatehouse at each end and a chapel or crypt in the centre, dedicated to St Thomas of Canterbury, in which Peter of Colechurch the architect was buried in 1205. In 1184 the Knights Templars removed from Holborn to the New Temple in Fleet Street, and in the following year the beautiful Temple church was built. All this activity of building proves that the citizens were wealthy and their city handsome. This is corroborated by the interesting work of Fitzstephen, the monk of Canterbury, which was written at this time. Fitzstephen has left us the first picture of London, and a very vivid one it is. He speaks of its wealth, commerce, grandeur, and magnificence,—of the mildness of the climate, the beauty of the gardens, the sweet, clear, and salubrious springs, the flowing streams, and the pleasant clack of the water-mills. Even the vast forest of Middlesex, with its densely wooded thickets, its coverts of game, stags, fallow deer, boars, and wild bulls is pressed into the description to give a contrast which shall enhance the prosperous beauty of the city itself. Fitzstephen's account of the sports of the people is particularly interesting. He tells how, when the great marsh that washed the walls of the city on the north (Moorfields) was frozen over, the young men went out to slide and skate and sport on the ice. Skates made of bones have been dug up of late years in this district. This sport was allowed to fall into disuse, and was not again prevalent until it was introduced from Holland after the Restoration. In the first year of Richard I. the court of aldermen ordained that for the future houses should not be built of wood, but that they should have an outside wall of stone raised 16 feet from the ground, and be covered with slate or baked tile. This ordinance must have fallen into desuetude, for the houses continued largely to be built of wood. We learn that most of the houses were plastered and whitewashed. One of the earliest objections which the Londoners made to the use of sea-coal was that the smoke from it blackened the white walls of their buildings. The first mayor of London was Henry Fitz Alwin, who was elected in 1189, and held the office until 1212.<sup>1</sup>

London had to pay heavily towards Richard's ransom; and, when the king made his triumphal entry into London after his release from imprisonment, a German nobleman is said to have remarked that had the emperor known of the wealth of England he would have insisted on a larger sum. The Londoners were the more glad to welcome Richard back in that the head of the regency, Longchamp, bishop of Ely, was very unpopular from the encroachments he made upon the city with his works at the Tower. The first charter by which the city claims the jurisdiction and conservancy of the river

<sup>1</sup> He was first admitted to the chief magistracy as bailiff, and there appears to have been considerable variety in the titles used at this time. We learn from the *Liber Albus* that the chief officer was sometimes called "lord mayor" and "chamberlain."

Thames was granted by Richard I. John granted several charters to the city, and it was expressly stipulated in Magna Charta that the city of London should have all its ancient privileges and free customs. The citizens opposed the king during the wars of the barons. In the year 1215 the barons having received intelligence secretly that they might enter London with ease through Aldgate, which was then in a very ruinous state, removed their camp from Bedford to Ware, and shortly after marched into the city in the night-time. Having succeeded in their object, they determined that so important a gate should no longer remain in a defenceless condition. They therefore spoiled the religious houses and robbed the monastery treasuries in order to have means wherewith to rebuild it. Much of the material was obtained from the destroyed houses of the unfortunate Jews, but the stone for the bulwarks was obtained from Caen, and the small bricks or tiles from Flanders. The church of St Mary Overy (now St Saviour's), Southwark, was begun in the year 1208, and in 1221 the foundation stone of the lady chapel at Westminster Abbey was laid by Henry III. We have alluded to the great change in the aspect of London and its surroundings made during the Norman period by the establishment of a large number of monasteries. A still more important change in the configuration of the interior of London was made in the 13th century, when the various orders of the friars established themselves there. The Benedictine monks preferred secluded sites; the Augustinians did not cultivate seclusion so strictly; but the friars chose the interior of towns by preference. The Black, Preaching, or Dominican Friars settled near Holborn, in what was afterwards Lincoln's Inn, in 1221, and removed to the ward of Castle Baynard in 1276, when the city wall was rebuilt to enlarge their boundaries. The district where the friary was built still retains its name. In 1224 John Iwyn or Ewin made over to the Grey Friars (or Franciscans) an estate situated in the ward of Farringdon Within and in the parish of St Nicholas in the Shambles, and on this site the first convent of the order was erected. The site is now occupied by the Blue Coat School. In 1241 the White Friars or Carmelites settled in a precinct or liberty between Fleet Street and the Strand which still retains their name. In 1253 the Austin Friars or Friars Eremites were founded in Broad Street ward, and the last of these friaries to be established was that of the Crutched or Crossed Friars in 1298. By the establishment of these religious houses two-thirds of the entire area of London was occupied by convents and hospitals. This is the most marked characteristic of Plantagenet London. We have no record of the date at which Temple Bar first marked out the extent of the liberties of the city, but as late as the end of the 14th century Fleet Street was described as being in the suburbs. During the Norman period the road from the city to Westminster was quite open, but soon afterwards a commencement was made in building. The Savoy was built in 1245 by Peter, earl of Savoy and Richmond, uncle of Eleanor, wife of Henry III.; and in this king's reign the friars of the order of St Mary de Arona are supposed to have established themselves near the site of Durham House (now the Adelphi). About the same time William Marshal, earl of Pembroke, founded and endowed a hospital and convent called St Mary Rouncivale at the village of Charing, so that in Henry III.'s reign there must have been several houses on the line of route to Westminster. Fitzstephen describes the latter place as follows:—"On the west also, higher up the bank of the river, the royal palace rears its head, an incomparable structure, furnished with a breastwork and bastions, situated in a populous suburb, at a distance of two miles from the city." In the reign of Edward I. the mayor offended the king, and the citizens were for a time deprived of their right of electing their chief magistrate. Gregory de Rokosley the mayor, the sheriffs, the aldermen, and other dignitaries of the city were summoned to appear on the 29th June 1285 before John de Kirkeby, treasurer, and the other justiciars of the king in the Tower of London for the purpose of holding inquests there. Now the mayor held that he was not bound to answer such a summons as this unless he had forty days' notice, so he resigned his mayoralty at Allhallows, Barking, and delivered the common seal of the city to Stephen Aawy and other aldermen, and then entered the Tower with the rest as an alderman only. This action incensed the king greatly, and John de Kirkeby was commanded to take over the mayoralty, a warden being appointed by the royal authority. This arrangement continued until 1297, when Edward granted the prayer of the citizens, and allowed them again to elect a mayor. Royal wardens had filled the mayor's seat from 1265 to 1268, but in the first charter of Edward I. the following concession was made:—"Also that the liberties of the city of London shall not be taken into the hand of his lordship the king for any personal trespass or personal judgment of any officer of the said city; and that no warden shall in the same or such pretext be appointed" (*Liber Albus*, translated by Riley, pp. 14, 181). In 1285 the first attempt was made to supply London with water artificially, and the great conduit in West Cheap (or Cheapside) was commenced. This lead cistern, which was constructed with stone, was supplied with water conveyed in leaden pipes from Tyburn. Soon afterwards a nobler building was erected in Cheapside. In 1290 the beloved Eleanor of Castile

died, and her husband erected stone crosses where her body had rested. Two of these crosses were in London, and there is some little difficulty in understanding why the two stations were so near each other. It has been suggested that the body really rested at St Paul's Cathedral. Cheapside Cross was erected by Michael of Canterbury, and cost £300, and Charing Cross, the most sumptuous of the series, cost £450. It was commenced by Richard de Crundale, and completed after his death by Roger de Crundale. In this same year (1290) the Jews were expelled from England. The district in London in which they had lived since William the Conqueror's day came to be called the Old Jewry, but when the Jews returned to England after many centuries of exile most of them settled in the neighbourhood of Aldgate.

Smithfield is mentioned by Fitzstephen as a market for horses, and from this writer we obtain its correct etymology (the smooth field). As early as the reign of Henry III. it had become known as the place for executions. Close by a grove of elm trees that gave their name to the place Sir William Wallace was executed in the year 1305, and there also Mortimer experienced a similar fate five and twenty years afterwards. The history of Smithfield from that day has been a record of executions, jousts, and markets.

In 1313 the celebrated order of the Knights Templar fell, and Edward II. gave their house in Fleet Street to Aymer de Valence, earl of Pembroke. At the earl's death the property passed to the Knights of St John of Jerusalem, who leased the Inner and Middle Temples to the students of the common law and the Outer Temple to Walter Stapleton, bishop of Exeter, and lord treasurer. The Charterhouse stands on a piece of ground which had been used in 1349 as a burial-place for the thousands who died in that year of the plague. In 1371 Sir Walter Manny founded there a priory of Carthusian monks.

One of those pageants for which the streets of London were so famous took place in 1356 when Edward the Black Prince brought the French king John a prisoner from the battle of Poitiers. It is not necessary to do more than allude to this here, as the incident is a part of English history.

We have now arrived at the period of one of the greatest Londoners that ever lived. The life of Geoffrey Chaucer throws a living interest around the several places with which he was associated. His father was a vintner in Thames Street, the garden of whose house was bounded by the Wall Brook. In 1374 Chaucer was appointed comptroller of the customs, and in the same year he went to live in the dwelling-house above the gate of Aldgate. In 1389 he was appointed clerk of the works at Westminster, the Tower of London, and other places. In March 1390 we find him on the Thames bank repair commission, and in May of the same year he was employed in setting up scaffolds in Smithfield for Richard II. and his queen (Anne of Bohemia) to see the jousts at that place. His duties took him to the mews for the king's falcons at Charing Cross, and in 1390 he was robbed of some of the king's money on the high road at Westminster. We thus see that traces of the "morning star of English poetry" are to be found in all parts of London.

In 1381 another of the stirring incidents of English history occurred in London. The threatening insurrection of Wat Tyler was suppressed when the leader was killed by Sir William Walworth in Smithfield. Before that the rebels had done great damage to property in London and Southwark. About this time two very important public works were commenced. Westminster Hall was repaired by Richard II. in 1397; the walls were carried up 2 feet higher, the windows were altered, and a new roof constructed. In 1411 the Guildhall was built, and the courts were removed from Aldermanbury.

During the troubles of the 15th century the authorities had seen the necessity of paying more attention to the security of the gates and walls of the city, and when Thomas Nevill, son of Thomas Lord Fauconbergh, made his attack upon London in 1471 he experienced a very spirited resistance. He first attempted to land from his ships in the city, but the Thames side from Baynard's Castle to the Tower was so well fortified that he had to seek a quieter and less prepared position. He then set upon the several gates in succession, and was repulsed at all. On the 11th of May he made a desperate attack upon Aldgate, followed by 500 men. He won the bulwarks and some of his followers entered into the city, but the portcullis being let down these were cut off from their own party and were slain by the enemy. The portcullis was drawn up, and the besieged issued forth against the rebels, who were soon forced to fly.

When Richard, duke of Gloucester, laid his plans for seizing the crown, he obtained the countenance of the lord mayor, Sir Edmund Shaw, whose brother Dr Shaw praised Richard at Paul's Cross. Crosby Hall, in Bishopsgate Street, then lately built, was made the lodging of the Protector. There he acted the accessible prince in the eyes of the people, for the last of the Plantagenets was another of the usurpers who found favour in the eyes of the men of London. His day, however, was short, and with the battle of Bosworth ends Plantagenet London.

**TUDOR (1485-1603).**—It was during this period that the first maps of London were drawn. No representation of the city earlier than the middle of the 16th century has been discovered, although it seems more than probable that some plans must have been produced at an earlier period.<sup>1</sup> The earliest known view is the drawing of Van den Wyngaerde in the Bodleian Library (dated 1550). The so-called Aggas map is a few years later in date; Braun and Hogenberg's map was published in 1572-73; and Norden's maps of London and Westminster are dated 1593. These maps were pasted upon walls, and must have been largely destroyed by ordinary wear and tear. It is curious that the only two existing copies of Aggas's map<sup>2</sup> were published in the reign of James I., although apparently they had not been altered from the earlier editions of Elizabeth's reign which have been lost. By the help of these maps we are able to obtain a very clear notion of the extent and chief characteristics of Tudor London. Henry VII. did little to connect his name with the history of London with the exception of the erection of the exquisite specimen of florid Gothic at Westminster Abbey, which is known by his name. Soon after this king obtained the throne he borrowed the sum of 3000 marks from the city, and moreover paid it at the appointed time. The citizens were so pleased at this somewhat unexpected occurrence that they willingly lent the king £6000 in 1488, which he required for military preparations against France. In 1497 London was threatened by the rebels favourable to Perkin Warbeck, who encamped on Blackheath on the 17th of June. At first there was a panic among the citizens, but subsequently the city was placed in a proper state of defence, and the king himself encamped in St George's Fields. On June 22 he entirely routed the rebels; and some time afterwards Perkin Warbeck gave himself up, and was conducted in triumph through London to the Tower.

About this time and in several subsequent years the sweating sickness raged in London. This disease (*Sudor Anglicus*) was considered peculiar to England. The sanitary condition of the houses at the time must have been most deplorable, and the plague and other diseases were constantly reappearing until the great fire cleared away all the abominable buildings that formed centres of infection.

During the reign of Henry VII. as well as during that of his son London was constantly the scene of gorgeous pageants. In 1512 the greater part of the palace of Westminster was burnt, and Henry VIII. had no suitable residence until 1529 when he obtained Wolsey's magnificent house called York Place, and named it Whitehall. That much of the present London was at this time in a wild and uncultivated condition is proved by a proclamation of Henry VIII., the object of which was "to preserve the partridges, pheasants, and herons from his palace at Westminster to St Giles's in the Fields, from thence to Islington, Hampstead, and Hounsey Park."

As the chief feature of Norman London was the foundation of monasteries, and the chief feature of Plantagenet London was the establishment of friaries, so Tudor London was specially characterized by the suppression of the whole of these religious houses, and also of the almost numberless religious guilds and brotherhoods. When we remember that about two-thirds of the area of London was occupied by these establishments, and that about a third of the inhabitants were monks, nuns, and friars, it is easy to imagine how great must have been the disorganization caused by this root and branch reform. One of the earliest of the religious houses to be suppressed was the hospital of St Thomas of Acon (or Acre) on the north side of Cheapside, the site of which is now occupied by Moter's Hall. The larger houses soon followed, and the Black, the White, and the Grey Friars, with the Carthusians and many others, were all condemned in November 1538.

Love of show was so marked a characteristic of Henry VIII. that we are not surprised to find him encouraging the citizens in the same expensive taste. On the occasion of his marriage with Catherine of Aragon the city was gorgeously ornamented with rich silks and tapestry, and Goldsmiths' Row (Cheapside) and part of Cornhill were hung with golden brocades. When on the eve of St John's Day, 1510, the king in the habit of a yeoman of his own guard saw the famous match of the city watch, he was so delighted that on the following St Peter's Eve he again attended in Cheapside to see the march, but this time he was accompanied by the queen and the principal nobility. The cost of these two matches in the year was very considerable, and, having been suspended in 1528 on account of the prevalence of the sweating sickness, they were soon afterwards forbidden by the king, and discontinued during the remainder of his reign. Sir John Gresham, mayor in 1548, revived

the march of the city watch, which was made more splendid by the addition of three hundred light horsemen raised by the citizens for the king's service.

The best mode of utilizing the buildings of the suppressed religious houses was a difficult question left unsolved by Henry VIII. That king, shortly before his death, founded St Bartholomew's Hospital, "for the continual relief and help of an hundred sore and diseased," but most of the large buildings were left unoccupied to be filled by his successor. The first parliament of Edward's reign gave all the lands and possessions of colleges, chantries, &c., to the king, when the different companies of London redeemed those which they had held for the payment of priests' wages, obits, and lights at the price of £20,000, and applied the rents arising from them to charitable purposes. In 1550 the citizens purchased the manor of Southwark, and with it they became possessed of the monastery of St Thomas, which was enlarged and prepared for the reception of "poor, sick, and helpless objects." Thus was founded St Thomas's Hospital, which was moved to Lambeth in 1870-71. Shortly before his death Edward founded Christ's Hospital in the Gray Friars, and gave the old palace of Bridewell to the city "for the lodging of poor wayfaring people, the correction of vagabonds and disorderly persons, and for finding them work." On the death of Edward VI. Lady Jane Grey was received at the Tower as queen, she having gone there by water from Durham House in the Strand. The citizens, however, soon found out their mistake, and the lord mayor, aldermen, and recorder proclaimed Queen Mary at Cheapside. London was then gay with pageants, out when the queen made known her intention of marrying Philip of Spain the discontent of the country found vent in the rising of Sir Thomas Wyatt, and the city had to prepare itself against attack. Wyatt took possession of Southwark, and expected to have been admitted into London; but finding the gates shut against him and the drawbridge cut down he marched to Kingston, the bridge at which place had been destroyed. This he restored, and then proceeded towards London. In consequence of the break down of some of his guns he imprudently halted at Turnham Green. Had he not done so it is probable that he might have obtained possession of the city. He planted his ordnance on Hay Hill, and then marched by St James's Palace to Charing Cross. Here he was attacked by Sir John Gage with a thousand men, but he repulsed them and reached Ludgate without further opposition. He was disappointed at the resistance which was made, and after musing a while "upon a stall over against the Bell Savadge Gate" he turned back. His retreat was cut off, and he surrendered to Sir Maurice Berkeley. We have somewhat fully described this historical incident here because it has an important bearing on the history of London, and shows also the small importance of the districts outside the walls at that period.

We now come to consider the appearance of London during the reign of the last of the Tudors. At no other period were so many great men associated with its history; the latter years of Elizabeth's reign are specially interesting to us because it was then that Shakespeare lived in London, and introduced its streets and people into his plays. In those days the frequent visitation of plagues made men fear the gathering together of multitudes. This dread of pestilence, united with a puritanic hatred of plays, made the citizens do all they could to discountenance theatrical entertainments. The queen acknowledged the validity of the first reason, but she repudiated the religious objection provided ordinary care was taken to allow "such plays only as were fitted to yield honest recreation and no example of evil." On April 11, 1582, the lords of the council wrote to the lord mayor to the effect that, as "her Majesty sometimes took delight in those pastimes, it had been thought not unfit, having regard to the season of the year and the clearance of the city from infection, to allow of certain companies of players in London, partly that they might thereby attain more dexterity and perfection the better to content her Majesty" (Analytical Index to the *Remembrancia*). When theatres were established the lord mayor took care that they should not be built within the city. The "Theatre" and the "Curtain" were situated at Shoreditch; the "Globe," the "Rose," and the "Hope" on the Banks; and the Blackfriars theatre, although within the walls, was without the city jurisdiction.

In 1561 St Paul's steeple and roof were destroyed by lightning, and the spire was never replaced. This circumstance allows us to test the date of certain views; thus Wyngaerde's map has the spire but Aggas's map is without it. In 1566 the first stone was laid of the "Burse," which owed its origin to Sir Thomas Gresham, and in 1571 Queen Elizabeth changed its name to the Royal Exchange, "so to be called from thenceforth and no otherwise."

A proclamation was issued in 1580 prohibiting the erection within 3 miles of the city gates of any new houses or tenements "where no former house hath been known to have been." In a subsequent proclamation the queen commanded that only one family should live in one house, that empty houses erected within seven years were not to be let, and that unfinished buildings on new foundations were to be pulled down. In spite of these restrictions

<sup>1</sup> "A map of London engraved on copper-plate, dated 1497," which was bought by Ferdinand Columbus during his travels in Europe about 1518-25, is entered in the catalogue of Ferdinand's books, maps, &c., made by himself and preserved in the cathedral library at Seville, but there is no clue to its existence. If it could be found it would be eagerly scanned by topographers, although possibly there would be little difference from the later maps that we possess, for the town did not extend very rapidly in those early times.

<sup>2</sup> One is in the Guildhall Library, and the other among the Pepysian maps in Magdalen College, Cambridge.

Protestants and Roman Catholics had gathered together one Sunday evening at the house of Count de Tillier, the French ambassador, to hear Father Drury (a converted Protestant) preach. As many as were able crowded into the room on the upper floor for that purpose, but those who could not get in were fain to remain on the floor below and listen to a preacher on the sacrament of penance. The floors both gave way, and a large number of persons were precipitated to a great depth and killed, both preachers being among the dead. With the death of James I. in 1625 the older history of London may be said to have closed. During the reign of his successor the great change in the relative positions of London within and without the walls had commenced. Before going on to consider the chief incidents of this change it will be well to refer to some features of the social life of James's reign. Ben Jonson places one of the scenes of *Every Man in his Humour* in Moorfields, which at the time he wrote the play had lately been drained and laid out in walks. Beggars frequented the place, and travellers from the village of Hoxton, who crossed it in order to get into London, did so with as much expedition as possible. Adjoining Moorfields were Finsbury Fields, a favourite practising ground for the archers. Mile End, a common on the Great Eastern Road, was long famous as a rendezvous for the troops. These places are frequently referred to by the old dramatists; Justice Shallow boasts of his doings at Mile End Green when he was Dagonet in Arthur's Show. Fleet Street was the show-place of London, in which were exhibited a constant succession of puppets, naked Indians, and strange fishes. The great meeting-place of Londoners in the day-time was the nave of old St Paul's. Crowds of merchants with their hats on transacted business in the aisles, and used the font as a counter upon which to make their payments; lawyers received clients at their several pillars; and masterless serving-men waited to be engaged upon their own particular bench. Besides those who came on business there were gallants dressed in fashionable finery, so that it was worth the tailor's while to stand behind a pillar and fill his table-books with notes. The middle or Mediterranean aisle was the Paul's Walk, also called the Duke's Gallery from the erroneous supposition that the tomb of Sir Guy Beauchamp, earl of Warwick, was that of the "good" Humphrey, duke of Gloucester. After the Restoration a fence was erected on the inside of the great north door to hinder a concourse of rude people, and when the cathedral was being rebuilt Sir Christopher Wren made a strict order against any profanation of the sacred building. Another of the favourite haunts of the people was the garden of Gray's Inn, where the choicest society was to be met. There, under the shadow of the elm trees which Bacon had planted, Pepys and his wife constantly walked. Mrs Pepys went on one occasion specially to observe the fashions of the ladies because she was then "making some clothes."

In those days of public conviviality, and for many years afterwards, the taverns of London held a very important place. The Boar's Head in Great Eastcheap was an inn of Shakespeare's own day, and the characters he introduces into his plays are really his own contemporaries. The "Mermaid" is sometimes described as in Bread Street, and at other times in Friday Street and also in Cheapside. We are thus able to fix its exact position; for a little to the west of Bow church is Bread Street, then came a block of houses, then Friday Street. It was in this block that the "Mermaid" was situated, and there appear to have been entrances from each street. What makes this fact still more certain is the circumstance that a haberdasher in Cheapside living "twixt Wood Street and Milk Street," two streets on the north side opposite Bread and Friday Streets, described himself as "over against the Mermaid tavern in Cheapside." The Windmill tavern occupies a prominent position in the action of *Every Man in his Humour*.<sup>1</sup> The Windmill stood at the corner of the old Jewry towards Lothbury, and the Mitre close by the Mermaid in Bread Street. The Mitre in Fleet Street, so intimately associated with Dr Johnson, also existed at this time. It is mentioned in a comedy entitled *Ram Alley* (1611), and Lilly the astrologer frequented it in 1610. At the Mermaid Ben Jonson may be supposed to have had such rivals as Shakespeare, Raleigh, Beaumont, Fletcher, Carew, Donne, Cotton, and Selden, but at the Devil in Fleet Street, where he started the Apollo Club, he was omnipotent. Herrick, in his well-known *Ode to Ben*, mentions several of the inns of the day.

Under James I. the theatre, which established itself so firmly in the latter years of Elizabeth, had still further increased its influence, and to the entertainments given at the many playhouses may be added the masques so expensively produced at court and at the inns of law. In 1613 "The Masque of Flowers" was presented by the members of Gray's Inn in the Old Banqueting House in honour of the marriage of the infamous Carr, earl of Somerset, and the equally infamous Lady Frances, daughter of the earl of Suffolk. The entertainment was prepared by Sir Francis Bacon at a cost of about £2000.

Charles I. and his councillors were filled with the same fear of the increasing growth of London which showed itself in the prohibitory proclamations of his two predecessors. In 1630 a proclamation was issued in which "the erection of any building upon a new foundation, within the limits of 8 miles from any of the gates of the City of London, or palace of Westminster," was forbidden. The privy council in the following year put this question to the lord mayor—"What number of mouths are esteemed to be in the City of London and the liberty?"—the answer to which was 130,268. These prohibitions were not allowed to remain a dead letter, and in 1632 Mr Palmer, a large landholder in Sussex, was fined by the Star Chamber in the sum of £1000 for living in London beyond the period prescribed in the proclamation of June 20th of that year. In April 1635 information was filed against Sir John Suckling the poet and others in the Court of Star Chamber for continuing to reside in London and Westminster. It was during this reign that the first great exodus of the wealthy and fashionable was made to the West End. The great square or piazza of Covent Garden was formed from the designs of Inigo Jones about 1632. The neighbouring streets were shortly afterwards built, and the names of Henrietta, Charles, James, King, and York Streets were given after members of the royal family. Great Queen Street, Lincoln's Inn Fields, was built about 1629, and named in honour of Henrietta Maria. Lincoln's Inn Fields had been planned some years before.

When the civil war broke out London took the side of the parliament, and an extensive system of fortification was at once projected to protect the town against the threatened attack of the royal army. A strong earthen rampart, flanked with bastions and redoubts, surrounded the City, its liberties, Westminster and Southwark, making an immense enclosure. Mount Street, Grosvenor Square, marks the spot of one of these fortifications called Oliver's Mount. In 1650 Cromwell allowed the Jews to return to England after a banishment of centuries, and those who settled in London mostly chose the neighbourhood of Aldgate as a place of residence. With the Restoration the separation of fashionable from city life became complete, and the West End grew into a formidable rival of the older London. In 1635 the game of pall mall was played in St James's Fields, on the site of St James's Square and Pall Mall, but during the Commonwealth this was discontinued, and some houses were built round about. The square was planned out in 1663, and it soon became the most fashionable place in London. A mall was then prepared in St James's Park which still retains its name. About the same time the great houses in Piccadilly were built. Clarendon, Berkeley, and Burlington Houses all appeared on the north side of that street about 1665.

London had been ravaged by plague on many former occasions, but the pestilence that commenced in December 1664 will ever live in history as "the Plague of London." On the 7th of June 1665 Samuel Pepys for the first time saw two or three houses marked with the red cross and the words "Lord, have mercy upon us," on the doors. The deaths daily increased, and business was stopped. Grass grew in the area of the Royal Exchange at Whitehall, and in the principal streets of the city. On the 4th of September, 1665, Pepys writes an interesting letter to Lady Carteret from Woolwich:—"I have stayed in the city till above 7400 died in one week, and of them about 6000 of the plague, and little noise heard day or night but tolling of bells." . . . The plague was scarcely stayed before the whole city was in flames, a calamity of the first magnitude, but one which in the end caused much good, as the seeds of disease were destroyed, and London has never since been visited by such an epidemic. On the 2d of September 1666 the fire broke out at one o'clock in the morning at a house in Pudding Lane. A violent east wind fomented the flames, which raged with fury during the whole of Monday and great part of Tuesday. On Tuesday night the wind fell somewhat, and on Wednesday the fire slackened. On Thursday it was extinguished, but on the evening of that day the flames again burst forth at the Temple. Some houses were at once blown up by gunpowder, and thus the fire was finally mastered. Many interesting details of the fire are given in Pepys's *Diary*. The distress of those who were made homeless by this calamity was great. The river swarmed with vessels filled with persons carrying away such of their goods as they were able to save. Some fled to the hills of Hampstead and Highgate, but Moorfields was the chief resort of the houseless Londoner. Soon paved streets and two-story houses were seen in that swampy place. The people bore their troubles heroically, and Henry Oldenburg, writing to the Hon. Robert Boyle on September 10, says, "the citizens, instead of complaining, discoursed almost of nothing but of a survey for rebuilding the city with bricks and large streets." Within a few days of the fire three several plans were presented to the king for the rebuilding of the city, by Christopher Wren, John Evelyn, and Robert Hooke. Wren proposed to build *ma* thoroughfares north and south, and east and west, to insulate all the churches in conspicuous positions, to form the most public places into large piazzas, to unite the halls of the twelve chief companies into one regular square annexed to Guildhall, and to make a fine quay on the bank of the river from Blackfriars to the

<sup>1</sup> Various changes in the names of the taverns are made in the folio edition of this play (1616) from the quarto (1601); thus the Mermaid of the quarto becomes the Windmill in the folio, and the Mitre of the quarto is the Star of the folio.

Tower. His streets were to be of three magnitudes—90 feet, 60 feet, and 30 feet wide respectively. Evelyn's plan differed from Wren's chiefly in proposing a street from the church of St Dunstan's in the East to the cathedral, and in having no quay or terrace along the river. In spite of the best advice, however, the jealousies of the citizens prevented any systematic design from being carried out, and in consequence the old lines were in almost every case retained. But, though the plans of Wren and Hooke were not adopted, it was to these two fellows of the Royal Society that the labour of rebuilding London was committed. Wren's great work, which has covered his name with renown, was the erection of the cathedral of St Paul's, and the many churches ranged round it as satellites. Hooke's task was the humbler one of arranging as city surveyor for the building of the houses. He laid out the ground of the several proprietors in the rebuilding of the city, and had no rest early or late from persons soliciting him to set out their ground for them at once. The first great impetus of change in the configuration of London was given by the great fire, and Evelyn records and regrets that the town in his time had grown almost as large again as it was within his own memory. Although for several centuries attempts had been made in favour of building houses with brick or stone, yet the carpenters continued to be the chief house-builders. As late as the year 1650 the Carpenters' Company drew

up a memorial in which they "gave their reasons that tynber buildings were more commodious for this citie than brick buildings were." The Act of Parliament "for rebuilding the city of London" passed after the great fire, gave the *coup de grace* to the carpenters as house-builders. After settling forth that "building with brick was not only more comely and durable, but also more safe against future perils of fire," it was enacted "that all the outsidies of all buildings in and about the city should be made of brick or stone, except doorecases and window frames, and other parts of the first story to the front between the piers," for which substantial oaken timber might be used "for conveniency of shops." A third severe blow in addition to the plague and the fire overtook London in the reign of Charles II. The king and his brother had long entertained designs against the liberties of the city, and for the purpose of crushing them two pretext were set up (1) that a new rate of market tolls had been levied by virtue of an act of common council, and (2) that a petition to the king, in which it was alleged that by the prorogation of parliament public justice had been interrupted, had been printed by order of the Court of Common Council. Charles directed a writ *quo warranto* against the corporation of London in 1683, and the Court of King's Bench declared its charter forfeited. Soon afterwards all the obnoxious aldermen were displaced and others appointed in their room by royal commission.

London in 1720. Reduced Facsimile of Map by J. Senex.

A new lord mayor and recorder and new sheriffs were appointed in the same manner. This decision of the Court of King's Bench was reversed in 1690. In the winter of 1683-84 a fair was held for some time upon the Thames. The frost, which commenced about seven weeks before Christmas and continued for six weeks after, was the greatest on record; the ice was 11 inches thick.

The revocation of the edict of Nantes in October 1685, and the consequent migration of a large number of industrious French Protestants, caused a considerable growth in the east end of London. The silk manufactories at Spitalfields were then established.

During the short reign of James II. the fortunes of the city were at their lowest, and nowhere was the arrival of the prince of Orange more welcomed. One of the first acts of James was to cause an indictment for high treason to be prepared against Alderman Cornish, who had been a zealous supporter of the Exclusion Bill. Sir John Eyles, who had never been sheriff nor was even a freeman of the city, was appointed lord mayor by the king in 1688 in succession to Sir John Shorter. When James found the danger of his position, and learned that William had landed, he sent for the mayor and aldermen and informed them of his determination to restore the city charter and privileges.

William III. cared little for London, the smoke of which gave him asthma, and when a great part of Whitehall was burnt in 1691 he purchased Nottingham House and made it into Kensington

Palace. For convenience of communication with London he had a broad road made through Hyde Park, which was lighted by lanterns at night. Kensington was then an insignificant village, but the arrival of the court soon caused it to grow in importance.

Although the spiritual wants of the city were amply provided for by the churches built by Sir Christopher Wren, the large districts outside the City and its liberties had been greatly neglected. The Act passed in the reign of Queen Anne for building fifty new churches (1710) not only helped to supply this want, but also gave a special architectural character to the suburbs.

EIGHTEENTH CENTURY.—With the accession of George I. a considerable change in the habits of all classes was introduced. At no previous time probably was public taste so low or manners more depraved. These two evils naturally were felt over the whole kingdom, but nowhere was their baneful influence more apparent than in the capital. Public buildings of the most tasteless character were raised, and streets of private houses were built that were positively painful in their ugliness. London thus grew to be the ugliest of cities, a character which it is only now beginning to throw off. London had gradually grown up by the side of the Thames and extended itself along the river's banks, which were skirted by a succession of handsome palaces. The inhabitants moved from place to place in boats, and the river was the chief highway. In the 18th century this state of things had ceased,

and other parts of the town were more largely built upon. The inhabitants used coaches and chairs more than boats, and the banks of the river were neglected. London could no longer be seen as a whole, and it grew into a mere collection of houses. In spite of all this the 18th century produced some of the most devoted of Londoners, - men who considered a day lived out of London as one lost out of their lives. Of this class Dr Johnson and Hogarth are striking examples. The exhibitions of vice and cruelty that were constantly to be seen in the capital have been reproduced by Hogarth, and had they not been set down by so truthful an observer it would have been almost impossible to believe that such enormities could have been committed in the streets of a great city. A few days after his accession George I. addressed the representatives of the city in these words: "I have lately been made sensible of what consequence the city of London is, and therefore shall be sure to take all their privileges and interests into my particular protection." On the following lord mayor's day the king witnessed the show in Chesham and attended the banquet at Guildhall. Queen Anne and the first three Georges were all accommodated, on the occasions of their visits to the City to see the show, at the same house opposite Bow church. In the time of Queen Anne and George I. David Barclay (the son of the famous apologist for the Quakers) was an apprentice in the house, but he subsequently became master, and had the honour of receiving George II. and George III. as his guests. There was a large balcony extending along the front of the house which was fitted with a canopy and hangings of crimson damask silk. The building, then numbered 108 Chesham, was pulled down in 1861. In September 1720 the bursting of the South Sea Bubble created the most fearful panic that London has ever seen. Trade was at a standstill, and many of the great merchants, goldsmiths, and bankers stopped payment, thus causing ruin to numberless families.

Early in the 15th century there was a considerable extension of building operations in the West End. About the year 1716 the earl of Burlington commenced building on the Ten Acres Field at the back of the gardens of Burlington House, and shortly afterwards the City authorities, who were proprietors of the Conduit Mead (containing 27 acres), followed his example. On June 1, 1717, the *Weekly Journal* announced that "the new buildings between Bond Street and Marylebone go on with all possible diligence, and the houses even let and sold before they are built." The parish of St George's, Hanover Square, was constituted in 1725. In 1715 Cavendish Square and the neighbouring streets had been planned out, but it was several years before the plan was completed. The foundation stone of Harcourt House (duke of Portland's) on the west side of the square, which is now about to be destroyed, was laid in 1722; and the north side, which was originally intended to be occupied by the mansion of the duke of Chandos, was still unfinished in 1761. St Peter's chapel in Vere Street, originally Oxford chapel, was built by Gibbs about 1724.

Still, however, the north of London remained unbuilt upon, and the open character of this part is well shown in the map given above. In 1756 and for some years subsequently the land bounded Montague House (now the British Museum) was occupied as a farm, and when in that year a proposal was made to plan out a new road the tenant and the duke of Bedford strongly opposed it. In 1772 all beyond Portland Chapel in Great Portland Street was country. Portman Square was laid out about 1764, but it was nearly twenty years before the whole was finished. It was built on high ground with an open prospect to the north, which gave it a name as a peculiarly healthy part of London. Mrs Montagu called it the Montpellier of England, and said "I never enjoyed my health as since she came to live in it." In a map of London dated 1773 the villages of Hackney, Stepney, Islington, Hoxton, Pancras, Marylebone, Paddington, Knightsbridge, and Chelsea are all shown as country out-kits of the town. Bedford House in Bloomsbury Square had its full view of Hampstead and Highgate from the back, and Queen's Square was built open to the north in order that the inhabitants might obtain the same prospect. Dr Huxtable recommended South Lambeth as a health resort on account of its situation on the banks of a river, free from the south-west wind blowing fresh from the country, and the north-east softened by blowing over the town.

In 1747 the Fleet ditch between Holborn Bridge and Fleet Bridge was covered over, and Stocks market was removed from the site of the Mansion House to the present Farringdon Street, and called Fleet market. On October 25, 1729, the first stone of the Mansion House was laid. Previously the first magistrates lived in several different houses. In 1759 Westminster Bridge was opened for passengers, and London Bridge ceased to be the only means of crossing the Thames at London. Blackfriars Bridge followed in 1769. A frost almost as severe as the memorable one of 1683-84 occurred in the winter of 1739-40, and the Thames was again the scene of a booby fair. In 1758 the houses on London Bridge were cleared away, and in 1760-62 several of the city gates were taken down and sold. Money was said to have fetched £166, Aldersgate £91, Aldgate £177, Cripplegate £90, and Ludgate £148. The statue of Queen Elizabeth

which stood on the west side of Ludgate was purchased by Alderman Gosling and set up against the east end of St Dunstan's church in Fleet Street, where it still remains.

The need of improving and opening out many of the streets of London was felt in the 18th century, but little or nothing was done, and the work was left to be accomplished in the present century. John Gwynn, a friend of Dr Johnson, paid considerable attention to this subject, and published in 1766 a work entitled *London and Westminster Improved, Illustrated by Plans*. Many of the author's suggestions have not been carried out, although they would often have been improvements upon what has been since attempted. Of such alterations as have subsequently been executed we may note here the widening of Swallow Street, a much-needed improvement, which was not carried out until the beginning of the present century, a square where Trafalgar Square now stands and some straight streets on the site of Durham House now the Adelphi, and a bridge where Waterloo Bridge was afterwards built.

Robert Adam and his brothers, Scotsmen who came to London under the protection of the earl of Bute, made a considerable improvement in the appearance of certain parts of London during the second half of the 18th century by the adoption of a combined system of architecture, in which several separate houses were grouped together to give the appearance of a continuous building. The Adelphi and Portland Place still remain good examples of their system. The brothers Adam were leaders in the revival of taste, and the interiors of their buildings are executed with much elegant detail. We have now come to a period when London outside the City may be considered as more important in many points than London within the liberties. "Why sir," said Dr Johnson to Boswell, "Fleet Street has a very animated appearance, but I think the tide of human existence is at Charing Cross." This speech was made in 1775, and in spite of the vast increase of London in every direction Charing Cross still retains this pre-eminent position.

The latter years of the 18th century were somewhat troublous ones for London, but it is only necessary here to barely mention the divisions between the court and the City relating to the election of Wilkes, and the Gordon riots of 1780, when the gates of Newgate were thrown open, and much property was destroyed by the mob.

NINETEENTH CENTURY. It is impossible to give here anything like a full account of the history of London during the 19th century. Since 1800 the City itself has been almost entirely rebuilt, and the suburbs on all sides have been vastly extended. Russell Square was built about 1804, and the district north of Bloomsbury was laid out at the same time. Bloomsbury Square had been built in 1665, and Bedford Square at the end of the 18th century. Alexander Gibson Hunter, in a letter to Constable the publisher written in March 1807, says, "Young Faulder and I walked over all the duke of Bedford's new feuing grounds, Russell Square, Tavistock Place, Brunswick Square, &c. The extent of them, and the rapidity of the buildings, is beyond all comprehension." Bedford and Russell Squares were for some years the favoured place of residence for the judges. To show how late has been the growth north of the New Road we may mention that at the beginning of the century grapes were ripened by the sun in the open air in gardens in Gower Street, and twenty-five dozen of nektarines were gathered in 1800 from three completely exposed trees in a garden in Upper Gower Street. Still later the richest flavoured cherry was gathered in abundance in the same place. When duelling was in fashion the duellists naturally chose out the most unfrequented places, and we thus obtain an idea where these places were situated. Chalk Farm for some years rivalled in popularity Windmillon Common, where the duke of York fought Colonel Lennox in 1789, Battersea Fields, where the duke of Wellington fought the earl of Winchester in 1829, and Putney Heath, where Pitt met Tierney in 1798, and Castlereagh and Canning fought in 1809. As late as 1843 a duel was fought at Chalk Farm between Lieutenant Monto and Colonel Fawcett, when the latter was killed.

In 1806 London saw the public funerals of three of England's greatest men. On the 8th February the body of Nelson was borne with great pomp from the Admiralty to St Paul's Cathedral, where it was interred in the presence of the prince of Wales and the royal dukes. Pitt was buried on 22d February, and Fox on the 10th October, both in Westminster Abbey.

The first exhibition of Winsor's system of lighting the streets with gas took place on the king's birthday (June 4) 1807, and was made in a row of lamps in front of the colonnade before Carlton House. Finsbury Square was the first public place in which gas lighting was actually adopted, and Grosvenor Square the last. On October 11, 1811, the first stone of Waterloo Bridge was laid, and on June 18, 1817, it was publicly opened. Southwark Bridge was opened in April 1819, and new London Bridge, the first stone of which had been laid on June 15, 1825, on August 1, 1831. Westminster and Blackfriars Bridges have been rebuilt within the last few years, and thus not one of the London bridges dates back farther than the present century. One of the greatest improvements in the West End was the formation of Regent Street, intended as a communication between Carlton House and the Regent's Park,

of the most important. The earliest description of London is that written by Fitzstephen, in the reign of Henry II., but first printed with Stow's *Survey* in 1598. Arnold's *Chronicle*, or the *Customs of London*, was first published in 1502. The first history was *A Survey of London*, by John Stow, 1588, 1603. The author died in 1665, and his work was continued by Anthony Munday and others (1618, 1633), and in the next century by J. Styrpe (1720, 2 vols. fol.; 1751-55, 2 vols. fol.). This last edition remains the standard history, and the remarks of Styrpe are very often quoted as those of Stow. E. Hutton's *New View of London* (1798) is very useful on account of its alphabetical list of streets, &c. Maitland's *History of London* was first published in 1 vol. folio in 1729, and was republished in 1746, 1760, 1769, and 1775—each edition in 2 vols. folio, the last being edited by the Rev. J. Entick. Lintick had himself published previously *A History of Survey of London*, &c., 1766. *A New and Complete History and Survey of the Cities of London and Westminster*, &c., by a society of gentlemen, revised by H. Chamberlain, appeared in 1770, and again, revised by W. Thornton, &c., in 1784; *A New History of London*, by J. Nodding, in 1774; and *A New and Universal History*, &c., of London and Westminster, &c., in 1775, fol. The first edition of Pennant's *London*, the most popular book ever written upon the subject, appeared in 1790. It has been frequently reprinted, and an index to the 4th edition was compiled by T. Bosnes, and published in 1814. A German translation was published at Nuremberg in 1791. *Antiquities of London and its Environs*, by John T. Smith, appeared in 1791-1800. Smith also published *Antiquities of the City of Westminster*, 1807, new edition, 1-37, 164; *Antiquary's Pocket of London*, 1815; *Westminster*, 1815-17; *City of London*, 1829; and *Antiquarian Remains in the Streets of London*, edited by C. Mackay, 1846. Other works are J. P. Malcolm's *Londinium Robinsonianum*, or an *Antient History and Modern Description of London*, 1803-7; *Annals of the Manners and Customs of London during the 18th Century*, 1808, 1810, and *Annals to the Nineteenth Century* to 1700, 1811; David Hudson's [*L. Puel's*] *London*, 1809-10, and *Walks through London*, 1817; B. Lintick's *History and Survey of London*, 1806, *Miscellaneous Travels*, 1808-9; H. Hamlet's *History of London* 1811. R. B. Barlow's *London and Walks*, 1814-16, vol. x., "London and Middlesex"; and R. Waksman's *Londinium Illustrata*, 1819; Thomas Allen's *History and Antiquities of London Westminster, and Southwark*, 1827-29, a most valuable work, with much information not to be found elsewhere; and E. W. Blythe's *Londinium*, 1829. *London* (edited by Charles Knight, 1841-44; revised by J. Walter, 1875-77) contains articles of considerable interest, but these are badly arranged, and the whole work is incomplete. Leigh Hunt's *The Town* (1818; new ed., 1829) is an interesting work, but without original research. *A Handbook to London*, by Peter Cunningham 1849; new ed., 1870, is an indispensable work of the latest time; and a new edition has been promised by Mr Murray at an early date. The various works on London by J. H. Jesse and John Evelyn are interesting, but wanting in accuracy. *The Curiousities of London* by the latter is of value. *Curious Oxford and New London* 1874-78, in 6 vols. 8vo; vols. 1-4 by Walter Thornbury, vols. 5-6 by J. Walter) is of special value on account of the almost entire want of it incorporated in Mr Cass's edition of *Didaxis Britannica*. *London* is a useful Handbook for London as it is. Besides these general works there are several *Chronicles of London* at various periods, some of which have been published by the Camden Society. The *Transactions of the London and Middlesex Antiquary*

There is no complete catalogue of books relating to London, but useful lists will be found in Anderson's *Book of British Topography*, 1851, and in Leander's *Bibliographer's Manual*, 1860. (H. R. W.)

One point worthy of special mention in connexion with the modern growth of London is the larger use of stone in building than at any previous period. The reason of this is that the increase in the value of land has made it worth the builder's while to spend more money on the building he raises. We might parody the remark on Augustus's influence in Rome and say-- the 19th century found London brick and will leave it stone.

*Literature.*—The books written upon London are so numerous that they would form a library by themselves; it is impossible here to do more than indicate some

Covent Garden Market, a Crystal Palace, a Tower of London (its jail and court-house), a St Paul's Cathedral, with Pall Mall, Piccadilly, Cheapside, &c. Among the more important buildings are the city-hall, the court-house, the city hospital, the lunatic asylum, the orphan asylum, the Roman Catholic convent. The educational institutions include the Collegiate Institute, Hellmuth Ladies' College, the Academy of the Sacred Heart, and the newly-founded Western University. • The chief industry is oil-refining: the crude oil being brought from Enniskillen wells, a distance of 40 miles. There are also railway-car works, boiler, and stove and other iron works, and chemical works, and furniture, farming implements, carriages, and w. goods are manufactured on an extensive scale. The value of the imports has increased from £176,400 in 1861 to £522,391

in 1881; and the value of the exports from £76,000 to £131,141. Three daily and five weekly newspapers and three monthly periodicals issue from the local press. The city is divided into seven wards, and is governed by a mayor and aldermen. First laid out in 1825-6, it returned a member in 1836, and was incorporated in 1840. The population was 15,826 in 1871, and 19,746 in 1881; but the East, West, and South London suburbs—really part of the city, though not yet included within the municipal boundaries—have a population of upwards of 10,000.

**LONDONDERRY**, a maritime county in the province of Ulster, Ireland, is bounded on the N. by the Atlantic, on the W. by Lough Foyle and Donegal, on the E. by Antrim and Lough Neagh, and on the S. by Tyrone. It has an irregular oval form, its greatest length being about 50 miles, and its greatest breadth about 40. The area comprises 513,388 acres, or about 802 square miles. The county consists chiefly of river valleys surrounded by elevated table-lands rising occasionally into mountains, while on the borders of the sea-coast the surface is generally level. The principal river is the Roe, which flows northwards from the borders of Tyrone into Lough Foyle below Newtown-Limavady, and divides the county into two unequal parts. Further west the Faughan also falls into Lough Foyle, and the river Foyle passes through a small portion of the country near its north-western boundary. In the south-east the Moyola falls into Lough Neagh, and the Lower Bann from Lough Neagh forms for some distance its eastern boundary with Antrim. The only lake in the county is Lough Finn on the borders of Tyrone, but Lough Neagh, which is included in Antrim, forms for about 6 miles its south-eastern boundary. The valley of the Roe is a line of division between two entirely different geological structures. To the east there is a basaltic tract in all respects similar to that in Antrim, except that on the Londonderry side of the Bann the dip of the strata is reversed and lies north-east. At Benyevenagh, which has an elevation of 1262 feet, the basalt reaches a thickness of 900 feet. It is succeeded by chalk lias, limestone, and red sandstone, the whole resting on primitive rock. The remainder of the county consists chiefly of mica-slate and primitive limestone, and includes the mountain of Sawel, with an elevation of 2236 feet, as well as other eminences approaching 2000 feet in height. Hornblende and granite frequently emerge above the slate, and limestone is not uncommon. Sandstone crops to the surface throughout nearly the whole of the valley of the Roe. Fine rock crystals are found in Finglen, near Dungiven, and in several other districts. Iron was at one time worked at Slieve Gullion, and is obtained in abundance in the bogs. There are a few unimportant veins of copper and lead.

**Agriculture.**—The excessive rainfall and the cold and uncertain climate are unfavourable for agricultural operations, and except in the valleys the soil is unsuitable for tillage. In the basalt region large tracts are partially submerged, and the hard and firm portions consist chiefly of rock. Along the sea-coast there is an extensive district of red clay formed by the decomposition of sandstone, and near the mouth of the Roe there is an extensive tract of a marly nature. Along the valleys the soil is often very fertile, and the elevated districts of the clay-slate region afford rich pasture for sheep.

In 1880 181,239 acres were under tillage, 206,044 were pasture, 5305 plantation, and 120,451 waste. The total number of holdings in the same year was 17,351, of which 1377 were under 1 acre. More than half of the total number were included in those between 5 and 15 acres and those between 15 and 30 acres, which numbered 5167 and 4348 respectively. The following table shows the area under the principal crops in 1855 and 1881:—

	Wheat.	Oats.	Other Cereals.	Potatoes.	Turnips.	Other Green Crops.	Flax.	Meadow and Clover.	Total.
1855	3,201	91,890	2,084	81,983	11,481	1,454	11,795	20,279	174,887
1881	1,817	74,680	3,102	34,437	12,491	3,390	18,989	28,062	186,918

The increase in the area under crops is due chiefly to the increase in that under flax and meadow, although there is an increase in all other crops except wheat and oats.

The number of horses since 1855 has increased very slightly—from 20,331 to 20,749, of which 17,053 were used for agricultural purposes. Cattle in 1855 numbered 102,185, and in 1881 only 96,693, an average of 25 to every 100 acres under cultivation, the average for Ireland being 25·8. The number of milch cows was 39,393. Sheep numbered 29,888 in 1855, and 30,161 in 1881, pigs in the same years numbering 22,828 and 23,946. Goats in 1881 numbered 4666, and poultry 368,436.

According to the latest return, the land in 1873 was divided amongst 2178 proprietors possessing 511,838 acres, with a total annual value of £364,732, the annual value per acre being 14s. 3d. Of the owners about 36 per cent. possessed less than 1 acre. As many as 153,419 acres were possessed by the Irish Society and seven of the livery companies of London—the Irish Society possessing 6075 acres; the Drapers' Company, 27,025; the Fishmongers', 20,509; the Grocers', 11,638; the Ironmongers', 12,714; the Mercers', 21,241; the Salters', 19,445; and the Skinners', 34,772. In addition to this Sir H. H. Bruce owned 20,801 acres, S. C. Bruce 13,651, the representatives of T. R. Richardson 18,159, Church Temporalities Commissioners 13,413, C. S. M'Causland 12,886, and J. B. Beresford 10,420.

**Manufactures.**—The staple manufacture of the county is linen. In 1880 the number of scutching mills was 185. The manufacture of coarse earthenware is also carried on, and there are large distilleries and breweries and some salt-works. There are important fisheries of salmon and eels on the Bann.

**Railways.**—The only railways in the county are those which skirt its northern and western boundary,—the Belfast and Northern Counties line passing by Cookstown and Coleraine to Londonderry, and another line connecting Londonderry with Enniskillen.

**Administration and Population.**—The county comprises 6 baronies, with 43 parishes and 1202 townlands. It is in the north-west circuit. Assizes are held at Londonderry, and quarter sessions at Coleraine, Londonderry, Magherafelt, and Limavady. Within the county there are 14 petty sessions districts. It includes two poor-law unions and portions of other three. Londonderry is in the Belfast military district and Omagh subdistrict. The county is represented in parliament by two members, and the boroughs of Londonderry (28,947) and Coleraine (6684) by one each. The population of the county, which in 1760 was only 46,182, had increased by 1821 to 193,869, and by 1841 to 222,461, but in 1851 had diminished to 192,269, in 1871 to 173,906, and in 1881 to 164,714, of whom 79,138 were males and 85,576 females. From the 1st May 1851 to 31st December 1881 the number of emigrants was 73,725. For every 1000 of the population the death-rate in 1880 was 19·2, the marriage-rate 4·2, and the birth-rate 23·2.

**History and Antiquities.**—At an early period the county was inhabited by the O'Canthans, or O'Cantrons, who were tributary to the O'Nials or O'Neils. Towards the close of the reign of Elizabeth the county was seized with the purpose of checking the power of the O'Neils, when it received the name of Coleraine, having that town for its capital. In 1609, after the confiscation of the estates of the O'Neils, the citizens of London obtained possession of the towns of Londonderry and Coleraine and adjoining lands, 60 acres out of every 1000 being assigned for church lands, and certain other portions to three native Irish gentlemen. The common council of London undertook to expend £20,000 on its reclamation, and elected a body of twenty-six for its management, who in 1613 were incorporated as the Irish Society, and retained possession of the towns of Londonderry and Coleraine, the remainder of the property being divided among twelve of the great livery companies of the city. Notwithstanding the expenditure of large sums by these companies in its management, their estates were afterwards sequestrated by James I., and in 1637 the charter of the Irish Society was cancelled. Cromwell restored the society to its former position, and Charles II. at the Restoration granted it a new charter, and confirmed the companies in the possession of their estates. In the insurrection of 1641 Money more was seized by the Irish, and Magherafelt and Bellaghy, then called Vintner's Town, burned, as well as other towns and villages. The most remarkable ancient ruin is, that of the Cyclopean fortress of the Giant's Scence or Ring, situated in the pass between Drumbo and Langanlea, the interior of which, 800 feet in diameter, is partly hollowed out of a knoll of basalt, by which it is enclosed on all sides except the north-east, where it is defended by a wall of great thickness, with access for only one person in a crotching posture. The most remarkable of the Druidical circles is that at Slack.

**Manus.** There are a large number of artificial caves. The most ancient castle of Irish origin is that of Carrickreagh; and of the castles erected by the English those of Dungiven, Salterstown, and Muff are still in good preservation. The old abbey of Dungiven, founded in 1109, and standing on a rock about 200 feet above the river Roe, is a very picturesque ruin.

**LONDONDERRY**, or **DERRY**, a county of a city, parliamentary borough, and the chief town of the county of Londonderry, is situated on an eminence rising abruptly from the west side of the river Foyle to the height of about 120 feet, 4 miles from the junction of the river with Lough Foyle, and 80 miles north-north-west of Belfast. It is still surrounded by an ancient rampart about a mile in circumference and having seven gates, but the buildings now extend considerably beyond this boundary. The summit of the hill, which is at the centre of the town, is occupied by a quadrangular area from which the main streets, which for the most part are spacious, diverge at right angles. Some of the original houses with high pyramidal gables remain, but they have been much modernized. The river is crossed by an iron bridge 1200 feet in length. The cathedral in the Later English style, and consisting of nave and aisles separated by pointed arches, with tower and spire at the west end, was completed in 1633 at a cost of £4000, contributed by the city of London. The building is 240 feet in length with a breadth of 62 feet, and the height of the tower and spire is 228 feet. The spire was added in 1788, when the old tower was raised 21 feet, and in 1802 the spire was rebuilt. The bishop's palace, erected in 1716, occupies the site of the abbey founded by Columba. The abbot of this monastery, on being made bishop, erected in 1164 Temple More or the "Great Church," one of the finest buildings in Ireland previous to the Anglo-Norman invasion. The original abbey church was called the "Black Church," but both it and the "Great Church" were demolished in 1600, and their materials used in fortifying the city. There is a large Roman Catholic cathedral. The court-house was completed in 1824 at a cost of about £34,000. For the free grammar school, founded in 1617, a new building was erected in 1814 at a cost of over £14,000. There are a number of charitable foundations. The staple manufacture of the town is linen, and there are also shipbuilding yards, iron-foundries, saw-mills, manure-works, distilleries, breweries, and flour-mills. The salmon fishery on the Foyle is also very valuable. The river affords facilities for a secure and commodious harbour, its greatest depth being 33 feet, with a depth of 12 feet at low water. The port has a considerable coasting trade with Great Britain, exporting agricultural produce and provisions. For the last five years its imports have averaged over £600,000 (chiefly grain and provisions), and its exports, which vary very greatly, over £10,000. In 1880 the number of vessels that entered the port was 1569, with a total tonnage of 335,544, the number that cleared 1452, with a tonnage of 326,178. Londonderry returns one member to parliament. The population of the city, which in 1857 was 19,399, had increased in 1871 to 25,242, and in 1881 to 28,947.

Derry, the original name of Londonderry, is derived from *Doire*, the "place of oaks." It owes its origin to the monastery founded by Columba in 546. From the 9th to the 11th century the town was frequently in the possession of the Danes, and was often burned and devastated, but they were finally driven from it by Murtagh O'Brien about the beginning of the 12th century. In 1311 it was granted by Edward II. to Richard de Burgo. After the Irish Society of London obtained possession of it, it was in 1613 incorporated under the name of Londonderry. The fortifications, which were begun in 1600, were completed in 1618 at a cost of nearly £9000. Its charter was confirmed in 1662 by Charles II. From April 18, 1690, the Protestants of the north defended themselves within its walls against James II. until the siege was raised in the following August. See the *History* by Hempton (1861).

**LONDONDERRY, ROBERT STEWART, SECOND MARQUIS OF (1769-1822)**, better known by his courtesy title of Viscount Castlereagh, which he held until the last year of his life, the statesman who brought about the union with Ireland, who was foreign minister for ten eventful years, who represented England at the congress of Vienna, and who was the recognized leader of the aristocratic and reactionary party which owed its being to the excesses of the French Revolution, was born on June 18, 1769, and was thus one year older than his great rival George Canning. His father, Robert Stewart of Ballylawn in the county of Londonderry, and Mount Stewart in Down, had represented the latter county in two Irish parliaments; and his marriage with Lady Sarah Seymour Conway, daughter of the earl of Hertford, in 1766, had brought him into connexion with many of the great Whig families of England, as did also his second marriage with the eldest daughter of Lord Camden. His elder son, the future minister, was educated at a school in Armagh, and proceeded in 1786 to St John's College, Cambridge. He spent only a single year at the English university, and was on his grand tour through Europe when he was summoned home by his father, who had just been created Lord Londonderry in the peerage of Ireland, to stand for the county of Down as the candidate of the smaller landholders against the influence of the marquis of Downshire. The election cost the new Lord Londonderry £60,000, a sum which crippled him for his whole life. But he was successful, and the young Stewart entered the Irish parliament as one of the few really independent members who sat there, bound by no ties to a great lord, but the representative of three thousand freeholders of the richest county of the most educated province of Ireland. He joined the opposition, like his father before him, and eagerly pressed for the extension of the franchise to the Roman Catholics, even going so far, said his enemies later, as to become a contributor to the *Northern Star* of Belfast, the organ of the seditious party in Ulster; but the great events of the French Revolution soon showed their influence on his opinions, as on those of most landed proprietors. His thoughts on politics already clearly pointed towards the necessity of a union between England and Ireland, a necessity by this time obvious to all political thinkers and practical politicians. But for the time he held firmly to the popular side, voting for the removal of Catholic disabilities, and the right of Irishmen to trade with India. At last, however, Lord Camden came over to Ireland, in March 1795, as lord-lieutenant, with Mr Pelham as his secretary, on a mission to tell the Catholics and reformers that they must expect no further relief and no further reform. He took much notice of his sister's step-son, young Robert Stewart, who was quite willing to be won over from the opposition, and who had in the previous year married Lady Emily Hobart, daughter of the late earl of Buckinghamshire, and near relative of many great political personages. Lord Camden used his influence to obtain for his brother-in-law a viscountcy as Viscount Castlereagh in October 1795, and in the following August an earldom as earl of Londonderry. In that same August 1796 he made Robert Stewart, who by his father's promotion had become Viscount Castlereagh, keeper of his signet, an honorary post which merely marked his accession to the Government, and in February 1797 acting secretary in the place of Mr Pelham. Taking office at a time when everything was at the height of confusion, Lord Castlereagh soon began to show his splendid administrative genius, which, indeed, consisted in his "infinite capacity for taking pains" and careful mastery of details. During the rebellion of 1798, when Lord Camden resigned in panic, Castlereagh showed all the qualities of a splendid

minister of police, and heartily co-operated with the wise measures of Lord Cornwallis, by which the rebellion was soon brought to an end. He was equally useful to Cornwallis in the second part of his mission to Ireland, namely, the union with England. The measure was to be carried; the means were bribery whether in honours or in money. The details of the passage of the measure through the House can be studied in the correspondences of Cornwallis and Castlereagh, in which appear clearly the utter disgust of Cornwallis at the work he was doing and the country he was in, and Castlereagh's pride in his successful manipulation of men. The Union carried (1800), then came the fulfilment of promises made to secure support or disarm opposition, and first in importance those to the Catholics. It was thoroughly understood between Pitt, Cornwallis, and Castlereagh that full rights of citizenship were to be given to the Catholics as a reward for the loyal behaviour of the greater men during the rebellion, and to induce them not to oppose the Union. But the promise was not fulfilled. Pitt had indeed promised to carry the measure; but the king's conscience was worked upon by Lord Loughborough, and to Pitt's surprise and disgust his resignation was accepted, and immediately followed by that of the abler half of the cabinet, and necessarily of Cornwallis and Castlereagh. With his resignation ends the first epoch of Castlereagh's political life. On very many occasions in his correspondence Cornwallis mentions him with warm praise of his "talents, temper, and judgment," and only qualifies his opinion in one place, when he says, on July 3, 1800, that "Littlehales very much surpasses Lord Castlereagh in the private management of mankind from his good humour and kind attention to everybody." Here Cornwallis touches the greatest political fault of Castlereagh, which destroyed his popularity and ruined his reputation—his want of sympathy for human weaknesses.

Castlereagh was sworn of the English privy council in December 1799, and returned to the first united parliament for the county of Down. He had no intention of permanently losing office by his advocacy of the Catholic claims, and therefore, instead of going into violent opposition like Canning and others of the late administration, he supported the weak Addington ministry, and in June 1802 was appointed president of the Board of Control. On Pitt's return to power in December 1804 he kept Castlereagh in office, and in 1805 made him secretary of state for war and the colonies, as well as president of the Board of Control. For the six months he held the war office he was Pitt's right hand in administration, as Canning was in debate. He now prepared a great expedition of thirty thousand men, who were to land in Hanover and make a diversion in northern Germany in favour of the Russians and Austrians. The expedition was too late to be of any use, but it deserves notice as illustrating Castlereagh's favourite idea that England should carry on "grande guerre," which was to appear to a greater extent later. His present tenure of office was but short, for Pitt's Government resigned on his death in January 1806.

When Pitt died, Castlereagh was prime mover in the attempt to make Lord Hawkesbury premier, and when that failed, sooner than give up all hope of place, he declared that he and his friends "looked to" Lord Grenville. Grenville, however, formed his ministry of "all the talents" out of the sections which followed Fox, Windham, and Sidmouth. The opposition was led in the House of Commons by Castlereagh and Canning. Now began the close association of these two celebrated men, each of whom hoped to lead the Tory party, and who did so in turn, both Irishmen from the same county of Londonderry, both in the prime of life, and distinguished

—the one for his surpassing eloquence, the other for his administrative powers. Each rival despised the other: Castlereagh, conscious of his high birth and noble connexions, looked down on the son of the actress; Canning, conscious on his side of his great talents for debate, looked down on the clumsy debater, and laborious parliamentary tactician, who looked to governing the country rather by a careful manipulation of boroughs and patronage than by eloquence and statesmanship. Castlereagh again, proud of his position as an ex-cabinet minister, pretended to lead Canning, who had held but inferior posts; while Canning, in his ardent devotion to the memory of Pitt, sneered at the man who had taken a seat in Addington's cabinet. This rivalry was increased almost to personal dislike by the marriage of Castlereagh's sister to the son and heir of that uncle of Canning's, Paul, in whose favour his own father had been disinherited, and who some years later was made Lord Garvagh. The rivals were not long in opposition, the new ministry resigning in 1807. The duke of Portland formed a new administration on strictly anti-Catholic principles, in which Castlereagh and Canning, both advocates of the Catholic claims, were secretaries of state, the former for war and the colonies, the latter for foreign affairs. During the two years they remained in office together each chafed at the other. The chief events connected with the war office during this tenure of office were the expeditions to Copenhagen, the Peninsula, and Walcheren. Of the Copenhagen expedition the chief credit or discredit must rest with Canning, but the merits of its execution rest entirely with Lord Castlereagh, who showed himself a war minister far superior to Dundas and Windham, and despatched in perfect secrecy a large military and naval expedition, which was swiftly and entirely successful. On the subject of the Portuguese expedition and the assistance to be afforded to the Spanish insurgents, the two secretaries were of different opinions. Canning sent the Spaniards officers, money, and arms in profusion, but was reluctant to send a great army, while Castlereagh planned the Portuguese expedition, chose Sir A. Wellesley to command it, and deserves the credit of Vimiera. Napier in his *Peninsular War* proves how wrong Canning was, how impossible it was to organize out of the Spaniards a force able to resist Napoleon, and how right Castlereagh was in believing in the efficacy of a British army. The Walcheren expedition went far utterly to ruin Castlereagh's reputation, and completed the difference between Canning and himself. Yet the conception was good. Castlereagh prepared the expedition with skill and secrecy, though with slight regard for men's lives, as appeared in his choice of the unhealthy island of Walcheren for debarkation, in his refusal to send enough doctors or hospital ships, and in his appointment of Lord Chatham to command in chief. In this appointment of Chatham appears the radical vice of his war administration: he looked before giving a command on active service to parliamentary influence, not tried ability. The failure of the expedition brought about a crisis in the cabinet. In April 1809 Canning had sent in his resignation to the duke of Portland, declaring that he could no longer serve with Castlereagh, but the matter was put off from time to time, and at length Canning consented to wait till the Walcheren expedition was over. In September he insisted once for all that something must be done, and then for the first time Castlereagh heard that his dismissal had been determined on for some months. He was naturally indignant, and, being unable to challenge Lord Camden, his benefactor, who had really behaved worst to him, or the old duke of Portland, he challenged Canning, who had throughout protested against the manner in which Castlereagh had been treated. On September 21 they met.

on Putney Heath, when Canning was slightly wounded in the thigh, and Castlereagh had a button shot off his coat. After this duel both resigned, and remained out of office two years, but Castlereagh did not intend to remain so, and through the influence of his aunt, old Lady Hertford, with the prince regent he was, after the refusal of Canning, offered the secretaryship of state for foreign affairs in March 1812 in the room of Lord Wellesley. On Perceval's assassination in May 1812, the leadership of the House of Commons was given to Castlereagh. The first ten years of Lord Liverpool's administration were the palmy days of the Tory aristocracy, and during them Lord Castlereagh was the guiding spirit of foreign policy in the cabinet, and the faithful interpreter of Lord Sidmouth's home policy in the House of Commons. Once in power, he perceived that Napoleon must be beaten in Germany, and that, though Lord Wellington's army in Spain must be supported to maintain the credit of English soldiers, and occupy as many French troops as possible, the important point was for the Russian and Prussian monarchs to be joined by the Austrian emperor, and follow up the blow Napoleon had dealt himself in his invasion of Russia. To bring Austria into the field manage the crown prince of Sweden, maintain the alliance of the great powers and the harmonious working of their armies and policies, Castlereagh gave the English ambassadors at the courts of Austria, Russia, and Prussia, full powers to correspond with each other, and follow the allied forces. The ability with which these instructions were carried out is to be read in the history of the whole campaign of 1813, and of the congresses of Mannheim and Frankfort. When the allies entered France, Castlereagh himself left England to attend the congress of Chatillon. He remained with armies of the allies, entered Paris with them, and signed the preliminaries of peace. Great was the applause he received on his return from the people, and above all in the House of Commons. The prince regent made him a Knight of the Garter, an honour which had only been conferred on two commoners, Sir R. Walpole and Lord North, for the last two hundred years, and when the allied sovereigns visited London they treated him with marked favour, so that it was no wonder, when he started to take his seat as British plenipotentiary at the congress of Vienna, he believed himself to be a great diplomatist. That he was mistaken in this was conclusively proved by that congress where, as Von Gentz said, England could have done anything, and did nothing. Throughout he supported Metternich, partly because Metternich's nature had mastered him, but more because he had imbibed a blind distrust of Russia. When the return of Napoleon from Elba put an end to the quarrels which were nearly ending in a general war between Prussia and Russia on the one side and England, France, and Austria on the other, and united all parties against him, Castlereagh returned to England, and expressed his confidence in a speedy termination of the new struggle, which indeed was closed at Waterloo. He signed the second peace of Paris on behalf of England, and on his return his father was created marquis of Londonderry. From this time his career can be sketched very shortly. At home the grand harvest of 1815 was followed by very bad ones, and great discontent existed both among the agricultural and manufacturing classes. The Government pursued the same tactics which had in 1793 united nearly all the upper classes in a fever of reaction; they established a secret committee which declared the existence of a widespread conspiracy, and it was often their spies who threw into the meetings of the discontented sufficient politics to make them look like conspiracies. The bad feeling existing came to a climax with the Peterloo massacre, and Lord Sidmouth introduced his Six Acts to check a network

of conspiracies which mostly did not exist. Castlereagh had to introduce the Six Acts in the House of Commons, and as usual spoke of the people with the air of hauteur and contempt which made him so particularly obnoxious to them. His foreign policy during these years was chiefly inspired by a real desire to maintain the peace of Europe, which he believed was only to be preserved by the harmony of all the monarchs and their foreign ministers, and to preserve this harmony he was so loth to differ from them on any subject that it was commonly believed among the people that he had signed the Holy Alliance. At the congress of Aix-la-Chapelle in 1818 it was for this reason that he recommended that France should be freed from the army of occupation. The death of George III. in January 1820 made no difference to Castlereagh, who was greatly in the favour of the new king, and who had no difficulty in supporting the Bill of Pains and Penalties against the queen. Scarcely was the excitement of the queen's trial and the king's coronation over, when Lord Londonderry, for he had succeeded to that title in this very year, accompanied the king to Hanover in October 1821 to discuss the revolutions in Greece and Spain with Metternich. The interviews which then took place are fully described in Metternich's *Autobiography* (vol. iii. pp. 552-560), and exhibit clearly the paramount influence of Metternich over Lord Londonderry, whom he persuaded to take part in a congress at Verona in the following year. While he was making preparations to start, he became possessed by many strange delusions, which clearly indicated that his mind was unlinged by over work, as it had been once before after the passing of the Union with Ireland. This soon became obvious to every one; the king noticed it; and the duke of Wellington sent a physician down to Fooks Cray to see him. The doctor found him suffering from melancholia, and ordered his razors to be taken away, but in spite of all precautions he procured a penknife and committed suicide on August 12, 1822. His body was conveyed to London to be buried in Westminster Abbey, and just as it was being lowered into the grave a cry of exultant hatred arose from that rabble he had so despised.

Castlereagh's character illustrates the strange difference which in corrupt times can exist between public and private morality. In private life he was a strictly honourable and affectionate man; he was a good husband, a good son, a good brother, and a good master; but even in his private relations that want of warmth which made Cornwallis declare he was utterly unlike an Irishman, and Wilberforce liken him to a fish, seems to have existed, and seems to have been part of his temperament. In public life he played quite a different part, and, though he had one or two firm political principles, as appears in his steady advocacy of Catholic emancipation, he seems as a rule to have regarded politics as a game, in which all means were fair to win, and very extraordinary some of his means appear to be. Though a very bad and confused speaker, he was very successful as a parliamentary leader, from the care with which he used his patronage, and the amount of votes he won by it. While not a great diplomatist, as the mastery Metternich obtained over him clearly proved, as an administrator he deserves the highest praise. steadily punctual to his work, never allowing arrears to accumulate, and never neglecting a detail; but his parliamentary necessities stood in his way: every appointment was given from a party point of view, and if, as in the case of Sir A. Wellesley, chance sometimes led him right, jobbing more often led him wrong. But the chief interest which centres in Lord Londonderry is that he was the last leader of an extinct class. The old aristocrats who lived by politics, and thought all means fair in politics, are gone

for ever, and with Londonderry's death the unnatural tension of the reaction from the excesses of the French Revolution ceased, and modern Conservatism, containing indeed many prejudices and an exaggerated admiration for what is fixed, came into being with its real sympathy for all mankind, which the old Tories, and more especially Lord Londonderry, would have despised.

The best materials for studying Londonderry's life and opinions are his *Despatches* edited by his brother, the third marquis, in 12 volumes. They are, however, very incomplete from the loss of the most valuable at sea in the wreck of the ship which was taking Mr Turner, Lord Londonderry's chosen biographer, to India. The *Corwallis Correspondence* for his Irish work, and the supplementary *Wellington Despatches* should also be used. Alison's *Lives* of Lord Castlereagh and Sir Charles Stewart are interesting reading, but abound with that celebrated author's usual faults, and should be corrected by Walpole's *History of England* from 1815. Of contemporary diaries, Rose's, Lord Colchester's, Romilly's, and Wilberforce's, with Pellet's *Life of Lord Sidmouth*, should be consulted, and Metternich's *Autobiography* for the later foreign policy. Mr Thornton has a short biography in his *Lives of the Foreign Secretaries* from 1800, which is chiefly valuable from his access to the unpublished memoranda of Lord Bexley, who as Mr Vansittart was chancellor of the exchequer, and helped to lead the Commons from 1812 to 1822. (H. M. S.)

LONG, GEORGE, an English scholar (1800-1879), was born at Poulton in Lancashire, on the 4th of November 1800. From Macclesfield grammar school he went to Trinity College, Cambridge, in 1818. He was elected Craven university scholar in 1821, together with Lord Macaulay and Professor Malden, took his degree in 1822 as wrangler and senior chancellor's medallist, and the next year gained a fellowship over the heads of his two distinguished rivals. In 1824 Long went out to be professor of ancient languages in the new university of Virginia. There he married his first wife, the widow of Colonel Selden. In 1828 he returned to England to accept the Greek professorship in the newly-founded university of London. His introductory lecture in 1828 was followed in 1830 by another entitled *Observations on the Study of the Latin and Greek Languages*. The etymological appendix to this lecture is of interest in the history of classical philology in England, as illustrating the scientific comparative method of teaching the Greek and Latin languages first adopted in the London university by himself and his colleague, Professor Key. He published a *Summary of Herodotus* (1829), and editions of Herodotus (1830-33) and Xenophon's *Anabasis* (1831). He was one of the founders of the Royal Geographical Society in 1830, and was for twenty years a member of the council, or officer of the society; in the same year he joined the committee of the Society for the Diffusion of Useful Knowledge, and was till 1846, when the society was dissolved, one of its most active workers. In 1831 he resigned his professorship and became editor of the society's *Quarterly Journal of Education* (1831-35), for which he wrote many articles. He wrote for the society's Library of Entertaining Knowledge the two volumes of *The British Museum: Egyptian Antiquities* (1832-36), and edited, improved, and wrote parts of the companion volumes *Elgin and Phigaleum Marbles* (1833) and *Townley Marbles* (1836). He planned and edited for the Library of Useful Knowledge a *Geography of America and the West Indies* (1841), of which he wrote a small part, and a *Geography of Great Britain: Part I. England and Wales*, part of which he also wrote himself. He contributed two maps of Egypt and Persia, ancient and modern, to the society's Atlas (1831). From 1833 to 1846 he was engaged on the great labour of his life, the editing of the twenty-nine volumes of the *Penny Cyclopædia*, to which he was also an extensive contributor of articles. The committee appointed Long and Charles Knight editors, but after the publication of a few numbers Knight took no part in the superintend-

ence of the work, and all the editorial labour was done by Long.

A more colossal and the final venture of the society was its *Biographical Dictionary*, of which Long was also appointed editor. He wrote numerous articles in the seven volumes which appeared (1842-44), but the great expense did not allow it to proceed beyond the letter A. Long was also a member of the committee of the Society for Central Education, instituted in London in 1837, and contributed two essays to its *Second and Third Publications* (1838-39). In 1837 he was called to the bar at the Inner Temple. He accepted in 1842 the professorship of Latin in University College, vacated by his friend Mr Key, which he resigned in 1846, on being appointed by the benchers of the Middle Temple their reader on jurisprudence and the civil law. *Two Discourses delivered in the Middle Temple Hall, with an Outline of the Course*, were published in 1847. He wrote all the articles on Roman law in the *Dictionary of Greek and Roman Antiquities*, edited by Dr William Smith (1842), and contributed also to the companion *Dictionaries of Biography* (1844-49) and *Geography* (1854-57). His translation of thirteen of Plutarch's *Lives*, with copious notes, first came out in five of Knight's weekly volumes under the title of *The Civil Wars of Rome* (1844-48). He planned and edited Knight's *Political Dictionary* (1845-46), a revision of articles from the *Penny Cyclopædia*. Knight published in parts his *History of France and its Revolutions*, 1789-1848 (1850).

In 1849 he left London and went to Brighton College, where he was classical lecturer until midsummer 1871. He was an excellent teacher, and was beloved by both masters and pupils. Whilst here he edited, at first jointly with the Rev. A. J. Maclean, and after that gentleman's death by himself, the *Bibliotheca Classica* series, to which he himself contributed the edition of Cicero's *Orations* (1851-62), a task for which his legal knowledge eminently qualified him. He also revised, making many corrections and additions, Maclean's editions of Juvenal and Persius (1867) and Horace (1869). He made for Bell's Grammar School Classics editions, with introductions and notes, of Cicero's *De Senectute* and *De Amicitia*, with a selection from his *Epistolæ* (1850), *Cæsar's Gallic War* (1853), and *Sallust's Catilina* and *Jugurtha* (1860). He also edited an *Atlas of Classical Geography* (1854). His translation of the *Thoughts of the Emperor M. Aurelius Antoninus* was published in 1862. The same year appeared anonymously the amusing and instructive little volume called *An Old Man's Thoughts about Many Things*. He was sixty-four when he issued the first of the five large octavo volumes of his *Decline of the Roman Republic*. In 1871 he resigned his post at Brighton College, and retired to Portfield, Chichester, to take a rest well-earned but from labours ill-rewarded. In 1873 the Queen, on the recommendation of Mr Gladstone, granted him a pension of £100 a year. At Portfield he completed his *Roman History* (1874), and translated *The Discourses of Epictetus, with the Encheiridion and Fragments* (1877). This was the last work of his laborious and useful life. He died after a long and painful illness on the 10th of August 1879.

In addition to the works already noticed, Long was the author of two papers in the *Journal of the Royal Geographical Society*, a few in the early numbers of the *Penny Magazine*, and several in the *Classical Museum* and *English Journal of Education*. He also wrote on "Grammar Schools," in Knight's *Store of Knowledge*.

Long has exercised by his writings, and indirectly through some of his London university pupils, a wide influence on the teaching of the Greek and Latin languages in England. The publication of the *Bibliotheca Classica* (begun in 1851) did important service, and set English scholars an excellent example, at a time when editions with English notes containing accurate learning and sound scholarship were, with very few exceptions, not to be found. Some of the volumes of this series still remain the standard

English editions. In the knowledge of Roman law Long stood by himself amongst English scholars, and his well-known articles on that subject were the first valuable contribution to the study from any English writer. He had also a profound knowledge of ancient geography. He was an excellent French, German, and Italian scholar, and also read Spanish. His extensive and accurate learning may be explained from the combination of a tenacious memory with a clear judicial intellect. His character was as elevated as his intellect. Its simplicity and manly independence may be seen partly in his writings. His faculty for discriminating evidence and his strong common sense appear in everything that he wrote. (J. J. M.)

**LONG BRANCH**, a fashionable seaside resort of the United States, in Ocean township, Monmouth county, New Jersey. The old village lies about a mile inland, but the watering-place proper is for the most part situated on the bluffs and plateau immediately above the beach. The bathing-grounds are excellent; there are fine drives along the beach in the vicinity; upwards of twenty thousand visitors can find accommodation in the hotels alone, of which there are no less than thirty-three; and there are besides hundreds of private residences occupied mainly by the wealthier classes from New York and Philadelphia. Since 1874 it can be reached directly from New York both by railway and by steamers. Long Branch has a corporation of seven commissioners. Its permanent population in 1880 was 3833, in 1882 about 5000.

**LONGEVITY** is a term that may be applied to express either the length or duration of life of any organism, or the prolongation of life to an advanced age. The first meaning is the more scientific of the two, as it may be applied to the duration of the life of any organism, although that duration may be relatively short; thus, we may contrast the longevity of the mould which lives only a few hours with that of the forest tree which has survived for centuries, or the longevity of the ephemeral insect with that of an eagle or a swan, whose lives may be prolonged to over a century. On the other hand, the second meaning is the more common, as when an instance of very advanced age is spoken of as an example of great longevity.

The information we possess as to the natural duration of life of the lower forms of plants and animals is very meagre, and it can scarcely be asserted that in all there is a natural period of life. A simple organism composed of cells, or even one more complicated but still having the organs necessary to life constructed upon a simple type, may continue to live and grow so long as external conditions are favourable. There may be no tendency to decay of tissue inherent in the organism, so that life may be prolonged until a change in external conditions, quickly or slowly, so affects the processes of nutrition as to make the continuance of life impossible beyond a certain time. It is also highly probable that in both the animal and vegetable worlds comparatively few individuals are permitted to live undisturbed for a sufficient length of time to allow any inherent tendencies to decay to show themselves. In the struggle for existence few individuals even reach maturity; at an early period they are used to support the lives of other and perhaps stronger organisms.

Excluding the lower forms of plants, as to the duration of whose lives we know nothing, the higher plants may be classed, according to duration of life, as follows:—*annuals*, or *semi-annuals*, which grow up in spring and die in autumn; *biennials*, which die at the end of the second year; and *perennials*, the duration of which may last from four to thousands of years. Succulent plants have a short life, lasting only one or two years; the formation of wood is necessary for prolonged vegetable existence. It has been pointed out that strongly scented plants have often a longer duration of life than those destitute of smell. Thus thyme, mint, hyssop, marjoram, sage, &c., can live for two years or longer; whilst lettuce, wheat, oats, barley, live no more

than a year. Trees of rapid growth, such as fir, birch, horse-chestnut, form soft wood, and have a comparatively short life; whilst hard-wood trees, such as the oak, grow slowly and live long. It is not, however, an invariable rule that trees yielding hard wood live longest. The beech, cypress, juniper, walnut, and pear all form hard wood, but they do not live so long as the lime, which forms a softer wood. Trees which are long in producing leaves and fruit, and which also retain these for a long time, live longer than those in which these changes occur quickly. Fruit-bearing trees, producing a sour harsh fruit in the wild state, have longer lives than those bearing sweet fruits in the cultivated state. By skilful pruning, or lopping off the branches and buds, the term of life of even short-lived plants may be lengthened.

According to Hufeland, the chance any plant has of attaining a great age depends on the following conditions:—(1) it must grow slowly; (2) it must propagate slowly and late in life; (3) it must have a certain degree of solidity and hardness in its organs, a sufficiency of wood, and the sap must not be too watery; (4) it must be large and have a considerable extent of surface; and (5) it must rise into the atmosphere. If we view a tree as consisting of an enormous number of buds clustered on a common stem in which the vessels or channels for the circulation of the sap remain pervious, and in which also new wood is formed annually, there seems to be no limit to age, provided external conditions are favourable. Many large trees have reached a vast age, as shown by the following table compiled by De Candolle:—

	Years.		Years.
Elm ( <i>Ulmus campestris</i> ).....	333	Oriental plane ( <i>Platanus orientalis</i> )	720
Cypress ( <i>Cupressus sempervirens</i> )	350	Cedar ( <i>Cedrus Libani</i> )	800
Charoiteum ( <i>Charoiteum patanoides</i> )	400	Lime ( <i>Tilia europæa</i> )	1076 1117
Ivy ( <i>Hedera Helix</i> )	150	Oak ( <i>Quercus Robur</i> )	810 1080 1500
Larch ( <i>Larix europæa</i> )	576	Yew ( <i>Taxus baccata</i> )	1214 1158
Chestnut ( <i>Castanea vesca</i> )	600		2588 2880
Orange ( <i>Citrus Aurantium</i> )	630	Taxodium ( <i>Taxodium distichum</i> )	3000 4000
Palm ( <i>Chorogylon and Cocos</i> )	600 700	Baobab ( <i>Adansonia digitata</i> )	5000
Olive ( <i>Olea europæa</i> )	700		

In the animal kingdom there is great variety as regards the duration of life, but no accurate data have yet been collected. Certain *Infusoria* have been watched during the whole period of their existence, which has not lasted more than forty-eight hours; on the other hand, *Actinia*, or sea anemones, may live to a long age, as shown by the case of a specimen of *Actinia mesembryanthemum*, still alive in Edinburgh, which belonged to Sir John Dalyell, and which must be at least about seventy years of age. It is highly probable that cold-blooded animals, such as fishes, frogs, toads, in which tissue-changes go on with extreme slowness, especially during a period of muscular inactivity, may live for many years. In the imperial fish-ponds of ancient Rome lampreys were said to have attained their sixtieth year; pike and carp have been ascertained to live a hundred and fifty years; tortoises have reached the age of one hundred years; and it is alleged by natives of India that the crocodile may live for at least a hundred years, and that there seems to be no limit to its time of growth. Many birds have a long period of life. Eagles and crows have been known to live a hundred years, and parrots have been kept in confinement for sixty years. Peacocks attain an age of twenty years; barn-door fowls live for a much shorter period, from six to twelve years. Small birds seem to have shorter lives than large ones. Blackbirds, goldfinches, and canaries have been known to live for twenty years; but many of the smaller birds attain an age of only five or six years.

Amongst mammals, the elephant is supposed to attain the greatest age, reaching above a hundred years; the camel generally lives to fifty years, and may live to eighty; the horse does not live more than forty years; the deer, thirty years; the ox, fifteen to twenty years; sheep, goats,

foxes, hares, rabbits, from seven to ten years; and dogs and pigs from fifteen to twenty years. Certain general statements may be made, which do not deserve to be termed laws, but which briefly express relations that undoubtedly exist in many cases between the degree of longevity enjoyed by any species of animal and the conditions of its existence.

1. A relation can often be traced between the duration of life and the time of the development of the animal *in utero*. To this statement there are many exceptions, as will be apparent from the following table, in which the periods of gestation are given on the authority of Professor Owen (*Comp. Anat. and Phys. of Vertebrates*, vol. iii.):—

Period of Gestation in Years.	Longevity in Years.	Name.	Period of Gestation in Days.	Longevity in Years.
Elephant .....	100	Monkey ( <i>Cebus</i> ) ..	150	10
Giraffe .....	40	Pig .....	120	15-20
Mare and Ass ..	30-40	Marmoset .....	120	Not known
Cow .....	15-20	<i>Lemur albicollis</i> ..	105	Not known
Human Being ..	80-100	Wolf, Jackal, Dog ..	64	15-20
Koe Deer .....	30	Cat .....	56	15-20
Red Deer .....	30	Bat ( <i>Vesperugo noctula</i> ) ..	40	Not known
Fallow Deer ..	245	Kangaroo .....	38	Not known
Hippopotamus ..	234	Not known.		

In the case of birds no relation of this kind can be discovered. For times of incubation of many birds see Owen, *op. cit.*, vol. ii. p. 257.

2. It would appear that the sooner a being attains maturity the sooner it propagates, and the shorter will be the duration of its life. The reproductive act may be regarded as the culminating act of the organism, requiring the highest degree of vitality, and involving the largest expenditure of energy. This act will therefore be performed when the organism has reached maturity; in some cases the animal reaches maturity late, in other cases early; but in all the epoch of maturity may be taken as about a fifth part of the whole duration of life. Thus the elephant and the human being do not reach maturity till say the twentieth year, and the period of longevity is about a hundred years; the horse, ass, and bull are mature in the third or fourth year, and live from fifteen to twenty years; sheep come to maturity in the second year, and live from eight to ten years; whilst rabbits and guinea pigs are mature within one year, and live only from four to five years. Here again there are exceptions, as, for example, the cat is mature before the end of the first year, and still it may live to the age of twenty years. Much information is still required on these points before a law can be formulated.

The question of longevity, however, probably presents the greatest interest in its relation to man. It is still a popular belief that the earliest inhabitants of the world possessed an incredible strength, were of an enormous size, and lived to a very great age; and the ages of the patriarchs before the flood are often taken literally, although the conditions making such long lives possible are at variance with those of human existence at the present day. In ancient history there are instances given of heroes who attained the age of several hundred years, but these must be regarded as mythical. For an interesting account of these, see Hufeland's *Art of Prolonging Life*, p. 62 sq.

The following are a few instances of extreme longevity which have been placed on record:—Margaret Patten, 137; the countess of Desmond, 145; Thomas Parr, 152; Thomas Damme, 154; John Ravin, 172; and Peter Torton, 185. There can be little doubt that the ages of these persons have been much exaggerated. They lived at a time when no accurate chronological records were kept, and when it was the habit to fix the dates of occurrences by comparing them in the memory with other events believed to have happened about the same time. Thus

there were many sources of fallacy, although the narrators no doubt believed their statements to be quite accurate. Still these were instances of prolongation of human life far beyond the usual limits, and there is no reason for doubting that they all lived till they were upwards of a hundred years of age.

Perhaps the best authenticated instance of this kind is that of the famous Thomas Parr of Shropshire. "He was a poor farmer's servant, and obliged to maintain himself by daily labour. When above one hundred and twenty years of age he married a widow for his second wife, who lived with him twelve years, and who asserted that during that time he never betrayed any signs of infirmity of age. Till his one hundred and thirtieth year he performed all his usual work, and was accustomed even to thresh. Some years before his death his eyes and memory began to fail, but his hearing and senses continued sound to the last. In his one hundred and fifty-second year his fame had reached London; and, as the king was desirous of seeing so great a rarity, he was induced to take a journey thither. 'This, in all probability, shortened his existence, which he otherwise might have preserved some years longer; for he was treated at court in so royal a manner, and his mode of living was so totally changed that he died soon after, at London, in 1635. He was one hundred and fifty-two years and nine months old, and had lived under nine kings of England. What was most remarkable in regard to this man is that, when his body was opened by Dr Harvey (the discoverer of the circulation of the blood), his internal organs were found to be in the most perfect state, nor was the least symptom of decay to be discovered in them. His cartilages even were not ossified, as is the case in all old people. The smallest cause of death had not yet settled in his body; and he died merely of a plethora, because he had been too well treated.'"—Hufeland, p. 71.

The late Sir George Cornewall Lewis attempted to show that all such narratives were so inaccurate as to reduce the ages of the parties to something under a hundred years, and he was disposed to think that there had been no instance of a human being attaining the age of a hundred years. But subsequent cases have shown that a few have attained that great age. In these cases the evidence has not been of a collateral kind, nor has it depended on human memory, but it has been established by written records. Scarcely a year passes without instances occurring in which the evidence that the deceased attained a hundred years cannot be controverted, and there is no doubt that, when a sufficient time from the beginning of the system of registration of births has elapsed, such cases will be more common.

The average duration of life in Europe is about thirty-four years. It oscillates between 28·18 years (Prussia) and 39·8 years (Schleswig-Holstein, Lauenburg). In Naples it is quoted at 31·65 years. This falls far short of the possible longevity, a circumstance chiefly to be accounted for by the great mortality in the early years of life. According to De Quatrefages, the duration of life is almost universally the same amongst the best known peoples. Laplanders live to a great age, men of from seventy to ninety years of age being common among them. The American Indians have apparently as long a life, on the average, as the white men living in the same locality. It would appear to be the same in the case of the negro. Prichard quotes from an official document of the State of New Jersey, showing that the census gave one negro centenarian in the 1000, but only one white centenarian in 150,000; on the other hand, the negro of the Senegal ages early, and does not live long. In his native place he is exposed to unhealthy influences which tell upon him, although he resists the bad effects of these longer and better than the white man; but when he is transplanted to America he enjoys a longer life.

The manner of life and nature of the occupation, apart from hereditary and special causes, have a most important influence on the duration of life. Few emperors or kings have attained the age of eighty; and, of more than three hundred popes, only six have exceeded the age of eighty. It

would seem that brain work is not unfavourable to longevity. It is almost proverbial that statesmen and judges often reach an advanced age. Many men famous in literature and science have lived to an old age. Thus from fifty to sixty we have Tasso, Virgil, Shakespeare, Molière, Dante, Pope, Ovid, Horace, Racine, Demosthenes; from sixty to seventy, Lavater, Galvani, Boccaccio, Fenelon, Aristotle, Cuvier, Milton, Rousseau, Erasmus, Cervantes; from seventy to eighty, Dryden, Petrarch, Linnaeus, Locke, Handel, Galileo, Swift, Roger Bacon, Charles Darwin; from eighty to ninety, Thomas Carlyle, Young, Plato, Buffon, Goethe, Franklin, Sir W. Herschel, Newton, Voltaire, Halley; and from ninety to one hundred, Sophocles, Leeuwenhoek, Michelangelo, Titian. Physicians are often long lived: Beerhaave, Haller, Gall, Darwin, Van Swieten, Fallopius, Jenner, Cullen, Galen, and Spallanzani died between seventy and eighty years of age, and Harvey, Duhamel, Pinel, Mergagni, Hoberden, and Ruysch between eighty and ninety; whilst the father of medicine, Hippocrates, is credited with one hundred and nine years.

A valuable set of statistics have been collected by Hirt (*Die Krankheiten der Arbeiter*) regarding the influence of trades on longevity. An abstract of these will be found in Buck's *Hygiene and Public Health*, vol. ii. pp. 71, 72.

The best indication of longevity in a community is given by the expectation of life from any given age. It is obtained by adding together the number of years which the entire population live from any specified age, and dividing the resulting total "years of life" by the number living at the year of age for which the expectation of life is desired (*English Life Table*, p. xxiii). Thus we may find the duration of the portion of human life which an individual at any age may expect to enjoy. Such calculations are of great value in connexion with assurance, and indeed in all pecuniary transactions in which the value of life contingencies are taken into account. They are the bases of all systems of life assurance. Life assurance companies have now been able to collect sufficient numbers of cases of their own experience on which to find trustworthy calculations showing the expectation of life at different ages. Such tables have really been compiled from selected cases, namely, from those who have assured, and consequently differ somewhat from those compiled on the broader data obtained from the whole population. The following table, derived from both sources of information, is given briefly to indicate the expectation of life, or the longevity, from various ages, reference being made for details to the article INSURANCE. The table to be read thus: a person at thirty years of age has an average expectation of living 33·3 years longer, or of attaining the age of 63·3 years.

Ages.	England and Wales. [Farr, 1838-54.]	Combined Experience of 17 English Offices, 1843.	Ages.	England and Wales. [Farr, 1838-54.]	Combined Experience of 17 English Offices, 1843.
0	40·9		80	13·9	13·77
10	47·4	48·36	70	8·7	8·54
20	39·9	41·49	80	5·1	4·78
30	33·3	34·43	90	2·9	2·11
40	26·7	27·28	95	2·2	1·28
50	20·1	20·18			

What are the physiological conditions in the human being that determine longevity? In the first place, there is the influence of heredity. Certain peculiarities of tissue are transmitted from parent to offspring that determine whether or not the tissue will remain for a lengthened period of time in a normal condition, or whether it will quickly yield to external influences and take on an abnormal action. As the life of the body is really the sum of the lives of its constituent parts, or in other words,

of the cellular elements composing it, it is evident that anything affecting the healthy action of these elements will affect the life of the body as a whole. In some individuals the tissues have what may be termed a hereditary taint, by which is meant a want of stability, so that they pass readily from a normal into an abnormal condition; and this is unfavourable to longevity.

In the next place, even healthy tissues capable of resisting ordinary influences may be unable to resist long-continued unfavourable conditions. In course of time slow changes begin in the tissue; these in turn affect the organ in which the tissue exists, and the organ, by improperly performing its functions, injures the organism. Thus it is that habitually breathing an impure atmosphere, eating improper food, saturating the body with drugs or with alcohol, over-exerting the nervous system by excitement or prolonged brain-work or worry, and sexual excesses debilitate the body by working slow but sure changes in the tissues which will inevitably tell upon the longevity of the individual.

But even in the most favourable conditions there seems to be a limitation to the healthy action of tissues, and old age comes on. Whether this is or is not the result of long hereditary transmission it is not of much practical importance to ask, as it is a state of things all flesh is heir to. But, if it be hereditary, as is highly probable, there is the satisfaction of knowing that hereditary states can be slowly influenced by individuals living in the best possible conditions and transmitting the influences of good moral and physical hygiene. If bad hereditary qualities are transmitted, good qualities have even a better chance of being perpetuated, as they favour the individual in the struggle for existence. Thus a race which has a low degree of longevity may acquire, by persistent attempts to live in the best conditions, a long average duration of life. This is also true, though to a less extent, of an individual life.

Each tissue has a life of its own; it is developed, reaches maturity, declines, and dies. It may be replaced by successive generations of similar tissues, but the power of reproduction of tissue becomes weakened, and by slow degrees the tissue may disappear, or it may become so altered as to be quite unlike what it was at first. By these tissue-changes functional changes of great importance to the body are brought about. Thus, as age comes on, the blood becomes poorer; respiration is less active; the vital capacity of the chest, that is the working quantity of air, is diminished; the temperature of the body is slightly increased, so that the aged are more sensitive to cold; the digestive organs are less vigorous; the walls of the arteries become hardened by earthy matter, and lose their elasticity; the veins become dilated, and the circulation is not efficiently performed; the teeth decay and disappear; the cartilages become calcified and hard; the skin is shrivelled and dry, and cutaneous respiration and excretion are less perfect; the hair whitens or falls off; the stature and the weight diminish. By and by muscular movements are less energetic and less precise; the hands tremble and the head shakes; and there is a tottering gait. The cartilages of the larynx ossify, the vocal cords lose their elasticity, and the voice becomes a shrill treble. Then the involuntary muscular tissues are affected so that the bladder is less powerful and defaecation is feeble. The transparent media of the eye become dimmed, the near point of vision is pushed back so that the old man becomes presbyopic, or far-sighted, and the power of accommodation, or focussing of the eye, is entirely lost; the delicate mechanism of the drum and bones of the ear is impaired, so that deafness results; and even touch becomes less delicate. Slowly the intellectual faculties become weakened, the emotions are blunted, and the memory becomes, by degrees less

trustworthy, and at last vanishes. Much of the time is now spent in sleep, and unless some intercurrent disease snaps the thread of life there is a slow ebbing of existence into natural death. Essentially these phenomena are due to delicate changes in the tissues, visible only with the aid of the microscope. These changes are those of wasting or atrophy, meaning a failure of nutrition, or fatty changes, or those caused by infiltration into the tissue of earthy matter, which soon destroys its healthy functions.

## HENRY WADSWORTH LONGFELLOW.

*Copyright, 1882, by Thomas Davidson.*

**HENRY WADSWORTH LONGFELLOW**, (1807–1882), the best known of American poets, was born on the 27th February 1807, at Portland, the metropolis of the State of Maine, to which his ancestor, William Longfellow, immigrated, in 1678, from English Hampshire. His father was Stephen Longfellow, a lawyer and United States congressman, and his mother, Zilpha Wadsworth, a descendant of John Alden and of "Priscilla, the Puritan maiden."

Longfellow's external life presents little that is of stirring interest. It is the life of a modest, deep-hearted gentleman, whose highest ambition was to be a perfect man, and, through sympathy and love, to help others to be the same. His boyhood was spent mostly in his native town, which he never ceased to love, and whose beautiful surroundings and quiet, pure life he has described in his poem "My Lost Youth." Here he grew up in the midst of majestic peace, which was but once broken, and that by an event which made a deep impression on him—the war of 1812. He never forgot

"the sea-fight far away,  
How it thundered o'er the tide,  
And the dead captains as they lay  
In their graves o'erlooking the tranquil bay,  
Where they in battle died."

The "tranquil bay" is Casco Bay, one of the most beautiful in the world, studded with bold, green islands, well fitted to be the Hesperides of a poet's boyish dreams. At the early age of fourteen Longfellow entered Bowdoin College at Brunswick, a town situated near the romantic falls of the Androscoggin river, about 25 miles from Portland, and in a region full of Indian scenery and legend. Here he had among his classfellows Nathaniel Hawthorne, George B. Cheever, and J. S. C. Abbott. During the latter years of his college life he contributed to the *United States Literary Gazette* some half-dozen poems, which are interesting for two reasons—(1) as showing the poet's early, book-mediated sympathy with nature and legendary heroisms, and (2) as being almost entirely free from that supernatural view of nature which his subsequent residence in Europe imparted to him. He graduated in 1825, at the age of eighteen, with honours, among others that of writing the "class poem,"—taking the fourth place in a class of thirty-eight. He then entered his father's law office, without intending, however, it would appear, to devote himself to the study of the law. For this profession he was, both by capacity and tastes, utterly unfitted, and it was fortunate that, shortly after his graduation, he received an offer of a professorship of modern languages in his alma mater. In order the better to qualify himself for this appointment, he came to Europe and spent three years and a half travelling in

France, Italy, Spain, Germany, Holland, and England, learning languages, for which he had unusual talent, and drinking in the spirit of the history and life of these countries. For an American, while still in a plastic state, to spend much time in Europe is a doubtful and, not unfrequently, a disastrous experiment, unfitting him for a useful, contented life in his own country. The effect of Longfellow's visit was twofold. On the one hand, it widened his sympathies, gave him confidence in himself, and supplied him with many poetical themes; on the other, it traditionalized his mind, coloured for him the pure light of nature, and rendered him in some measure unfit to feel or express the spirit of American nature and life. His sojourn in Europe fell exactly in the time when, in England, the reaction against the sentimental atheism of Shelley, the pagan sensitivity of Keats, and the sublime, Satanic outcastness of Byron was at its height; when, in the Catholic countries, the negative exaggerations of the French Revolution were inducing a counter current of positive faith, which threw men into the arms of a half-sentimental half-aesthetic mediævalism; and when, in Germany, the aristocratic paganism of Goethe was being swept aside by that tide of dutiful, romantic patriotism which flooded the country, as soon as it began to feel that it still existed after being run over by Napoleon's war-chariot. When, in 1829, he returned to assume his duties at Bowdoin College, he saw the world and man no longer in the clear effulgence of nature, but in the subdued and tinted light that comes through painted cathedral windows, or in the reflected rays that fall from somnambulous moons. He remained six years at Bowdoin College. In his twenty-fourth year (1831) he married Miss Mary S. Potter, one of his "early loves," and in 1833 published, first, a small volume of translations from the Spanish, with an introductory essay on the moral and devotional poetry of Spain, and then part of *Outre-Mer*, a youthfully ebullient work, for which a fitting title would have been "Poetry and Truth from my Travels." The latter contained some translations from the French, and was completed in 1835.

In 1835 Longfellow was chosen to succeed George Ticknor as professor of modern languages and belles-lettres in Harvard College, Cambridge, Mass., the oldest and most illustrious institution of higher learning in the country. On receiving this appointment, he paid a second visit of some fifteen months to Europe, this time devoting special attention to the Scandinavian countries and Switzerland. During this visit he lost his wife, who died at Rotterdam, November 29, 1835. The poet speaks of her in "Footsteps of Angels" as

"the Being Beauteous  
Who unto my youth was given,  
More than all things else to love me,  
And is now a saint in heaven."

On his return to America in 1836, Longfellow took up his residence in Cambridge, and began to lecture and write. In his new home he found himself amid surroundings entirely congenial to him. Indeed, there are few places in the world which a man of learning, refinement, sociability, and liberal views would rather choose for a residence than Cambridge. Its spaciousness and free rural aspect, its old graveyards and towering elms, its great university, its cultivated society, for admission to which unabsorbed wealth is a positive disqualification, and its vicinity to humane, substantial, busy Boston, are all attractions for such a man. In 1837–38 several essays of Longfellow's appeared in the *North American Review*, and in 1839 he published *Hyperion*, and his first volume of original poetry, entitled *Voices of the Night*. The former, a poetical account of his travels, had, at the time of its

publication, an immense popularity, due mainly to its sentimental romanticism. At present few persons beyond their teens would care to read it through, so unnatural and stilted is its language, so thin its material, and so consciously mediated its sentiment. Nevertheless it has a certain historical importance, for two reasons—(1) because it marks that period in Longfellow's career when, though he had left nature, he had not yet found art, and (2) because it opened the sluices through which the flood of German sentimental poetry flowed into the United States—a flood whose waters, after forty years, are not yet assuaged. The *Voices of the Night* contains some of his best minor poems, e.g., "The Psalm of Life" and "Footsteps of Angels." In 1841 Longfellow published a small volume of *Ballads and other Poems*, containing some of his most popular pieces, e.g., "The Skeleton in Armour," "The Wreck of the Hesperus," "The Village Blacksmith," "To a Child," "The Bridge," "Excelsior." In 1842 he paid a third brief visit to Europe, spending the summer on the Rhine. During his return-passage across the Atlantic he wrote his *Poems on Slavery*, which he published the same year, with a dedication to Channing. These poems went far to wake in the youth of New England a sense of the great national wrong, and to prepare them for that bitter struggle in which it was wiped out at the expense of the lives of so many of them. In 1843 he married again, choosing this time Miss Frances F. Appleton of Boston, a daughter of Hon. Nathan Appleton, one of the founders of Lowell, and a sister of Thomas G. Appleton, himself no mean poet.

About the same time he bought, and fixed his residence in, the house in which he had formerly only been a lodger, an old "revolutionary house," built about the beginning of last century, and occupied by General Washington at the time when he took command of the United States army in 1776. This quaint old wooden house, which stands in the midst of a large garden full of splendid elms, continued to be his chief residence till the day of his death. Of the lectures on Dante which he delivered about this time, James Russell Lowell says:—"These lectures, illustrated by admirable translations, are remembered with grateful pleasure by many who were thus led to learn the full significance of the great Christian poet." Indeed, as a professor, Longfellow was eminently successful. Shortly after the *Poems on Slavery*, there appeared in 1843 a more ambitious work, *The Spanish Student*, a kind of sentimental "Morality," without any special merit but good intention. If published nowadays it would hardly attract notice; but in those gushing, emotion-craving times it had considerable popularity, and helped to increase the poet's now rapidly widening fame. A huge collection of translations of foreign poetry edited by him, and entitled *The Poets of Europe*, appeared in 1845, and, about the same time, a few minor poems—songs and sonnets—under the title *The Belfry of Bruges*. In 1847 he gave to the world the greatest of all his works, and the one which will carry his name down to posterity—*Evangeline, a Tale of Acadie*. It was, in some degree, an imitation of Goethe's *Hermann and Dorothea*, and its plot, which was derived from Hawthorne's *American Note-Books*, is even simpler than that of the German poem, not to say much more touching. At the violent removal by the British Government of a colony of French settlers from Acadie (Nova Scotia) in 1755, a young couple, on the very day of their wedding, got separated and carried in different directions, so that they lost all trace of each other. The poem describes the wanderings of the bride in search of her lover, and her final discovery of him as an old man on his death-bed, in a public hospital which she had entered as a nurse. Slight as the story is, it is worked out into

one of the most affecting poems in the language, and gives to literature one of its most perfect types of womanhood and of "affection that hopes and endures and is patient." Though written in a metre deemed foreign to English ears, the poem immediately attained a wide popularity, which it has never lost, and secured to the dactylic hexameter a recognized place among English metres.

In 1849 Longfellow published a novel of no great merit, *Kavanaugh*, and also a volume of poems entitled *The Seaside and the Fireside*, a title which has reference to his two homes, the seaside one on the charming peninsula of Nahant, the fireside one in Cambridge. One of the poems in this collection, "Resignation," has taken a permanent place in literature; another, "Hymn for my Brother's Ordination," shows plainly the nature of the poet's Christianity. His brother, the Rev. Samuel Longfellow, is a minister of the Unitarian Church.

Longfellow's genius, in its choice of subjects, always oscillated between America and Europe, between the colonial period of American history and the Middle and Romantic Ages of European feeling. When tired of the broad daylight of American activity, he sought refuge and rest in the dim twilight of mediæval legend and German sentiment. In 1851 appeared *The Golden Legend*, a long lyric drama based upon Hartmann von Aue's beautiful story of self-sacrifice, *Der arme Heinrich*. Next to *Evangeline*, this is at once the best and the most popular of the poet's longer works, and contains many passages of great beauty. Bringing his imagination back to America, he next applied himself to the elaboration of an Indian legend. In 1854 he resigned his professorship. In the following year he gave to the world the Indian Edda, *The Song of Hiawatha*, a conscious imitation, both in subject and metre, of the Finnish epic, the *Kalevala*, with which he had become acquainted during his second visit to Europe. The metre is monotonous and easily ridiculed, but it suits the subject, and the poem is very popular. In 1858 appeared *The Courtship of Miles Standish*, based on a charming incident in the early history of the Plymouth colony, and, along with it, a number of minor poems, included under the modest title, *Birds of Passage*. One of these is "My Lost Youth."

Two events now occurred which served to cast a gloom over the poet's life and to interrupt his activity,—the outbreak of the civil war, and the tragic fate of his wife, who, having accidentally allowed her dress to catch fire, was burnt to death in her own house in 1861. It was long before he recovered from the shock caused by this terrible event, and in his subsequent published poems he never ventured even to allude to it. When he did in some measure find himself again, he gave to the world his charming *Tales of a Wayside Inn* (1863), and then a "second flight" of his *Birds of Passage*. Among the latter is a poem entitled "The Children's Hour," which affords a glance into the home life of the widowed poet, who had been left with five children—two sons, Ernest and Charles, and three daughters,

"Grave Alice, and laughing Allegra,  
And Edith with golden hair."

The *Birds of Passage* was succeeded by a small volume entitled *Flower de Luce* (1866), which contains, among other fine things, the beautiful "threnos" on the burial of Hawthorne, and "The Bells of Lynn." Once more the poet sought refuge in mediæval life by completing his translation of the *Divina Commedia*, parts of which he had rendered into English as much as thirty years before. This work appeared in 1867, and gave a great impulse to the study of Dante in America. It is a masterpiece of literal translation. Next came the *New England Tragedies* (1868), and *The Divine Tragedy* (1871), which found no large

public. In 1868-69 the poet visited Europe, and was everywhere received with the greatest honour. In 1872 appeared *Three Books of Song*, containing translated as well as original pieces, in 1873 *Aftermath*, in 1874 *The Hanging of the Crane*, and in 1875 *The Mask of Pandora*, and other Poems. Among these "other poems" were "The Hanging of the Crane," "Morituri Salutamus," and "A Book of Sonnets." *The Mask of Pandora* is a proof of that growing appreciation of pagan naturalism which marked the poet's later years. Though not a great poem, it is full of beautiful passages, many of which point to the riddle of life as yet unsolved, a conviction which grew ever more and more upon the poet, as the ebullieny of romanticism gave way to the calm of classic feeling. In the "Book of Sonnets" are some of the finest things he ever wrote, especially the five sonnets entitled "Three Friends of Mine." These "three friends" were Cornelius Felton, Louis Agassiz, and Charles Sumner, whom he calls

"The noble three,  
Who half my life were more than friends to me."

The loss of Agassiz was a blow from which he never entirely recovered; and, when Sumner also left him, he wrote—

"Thou hast but taken thy lamp and gone to bed;  
I stay a little longer, as one stays  
To cover up the embers that still burn."

He did stay a little longer; but the embers that still burnt in him refused to be covered up. He would fain have ceased writing, and used to say, "It's a great thing to know when to stop"; but he could not stop, and did not stop, till the last. He continued to publish from time to time, in the magazines, poems which showed a clearness of vision and a perfection of workmanship such as he never had equalled at any period of his life. Indeed it may be said that his finest poems were his last. Of these a small collection appeared under the title of *Keramos, and other Poems* (1878). Besides these, in the years 1875-78 he edited a collection of *Poems of Places* in thirty-one small volumes. In 1880 appeared *Ultima Thule*, meant to be his last work, and it was nearly so. In October 1881 he wrote a touching sonnet on the death of President Garfield, and in January 1882, when the hand of death was already upon him, his poem, *Hermes Trismegistus*, in which he gives utterance, in language as rich as that of the early gods, to that strange feeling of awe without fear, and hope without form, with which every man of spotless life and upright intellect withdraws from the phenomena of time to the realities of eternity.

In the last years of his life he suffered a great deal from rheumatism, and was, as he sometimes cheerfully said, "never free from pain." Still he remained as sunny and genial as ever, looking from his Cambridge study windows across the Brighton meadows to the Brookline hills, or enjoying the "free wild winds of the Atlantic," and listening to "The Bells of Lynn" in his Nahant home. He still continued to receive all visitors, and to take occasional runs up to Castine and Portland, the homes of his family. About the beginning of 1882, however, a serious change took place in his condition, and he was obliged to withdraw from the public gaze. Dizziness and want of strength confined him to his room for some time, and, although after some weeks he partially recovered, his elasticity and powers were gone. He now acknowledged the receipt of letters with a printed form. At last the end came. On the 19th March he was seized with what proved to be peritonitis, with violent paroxysms of vomiting and pain, which continued until the 22d. The 23d was passed in a torpid condition, which, though it vanished on the morning of the 24th, returned in the course of the day, and passed, by insensible degrees, into the profound sleep of death.

The poet was buried on the 26th, near his "three friends," in Mount Auburn cemetery. The regret for his loss was universal; for no modern man was ever better loved or better deserved to be loved.

Longfellow was made an LL.D. of Bowdoin College in 1828, at the age of twenty-one, of Harvard in 1859, and of Cambridge (England) in 1868, and D.C.L. of Oxford in 1869. In 1873 he was elected a member of the Russian Academy of Science, and in 1877 of the Spanish Academy.

In person, Longfellow was rather below middle height, broad-shouldered, and well built. His head and face were extremely handsome, his forehead broad and high, his eyes full of clear, warming fire, his nose straight and graceful, his chin and lips rich and full of feeling as those of the Praxitelean Hermes, and his voice low, melodious, and full of tender cadences. His hair, originally dark, became, in his later years, silvery white, and its wavy locks combined with those of his flowing beard to give him that leonine appearance so familiar through his later portraits. Charles Kingsley said of Longfellow's face that it was the most beautiful human face he had ever seen. And many agreed with him.

In trying to form an estimate of Longfellow, we are not obliged, as in the case of so many other poets, to distinguish the poet from the man, or to degrade the nature of the former by making it an excuse for the foibles of the latter. In Longfellow, the poet was the flower and fruit of the man. His nature was essentially poetic, and his life incomparably the greatest of his poems. Those who knew only the poems he wrote could form but a faint notion of the harmony, the sweetness, the manliness, and the tenderness of that which he lived.

Of the two orders of poets distinguished by Aristotle—that of the inspired or plastic, and that of the versatile or observant—Longfellow belonged distinctly to the latter. Nature did not come to him as to a Pythia seated on a tripod, and fill him with passion expressible only in rhythmic prophecy; she did not even call him as a private secretary, and dictate to him her secret messages of love and tenderness, justice and watchfulness, freedom and immortality. He went to nature, sometimes as the Angel of the Annunciation, revealing to her that she was pregnant with divinity, sometimes as a priest pronouncing a benediction over her. What he would have been as a poet, if, instead of visiting Europe in early life and drinking in the spirit of the Middle Age under the shadows of cathedral towers, that point upwards to a world above nature, and backwards to a time when that world darkened the face of nature, he had, like Whittier, grown old amid the uncathedralled paganisms of American scenery and life, we can only guess from his earlier poems, which are as naturalistic, fresh, and unmythical as could be desired; but certain it is that, from his long familiarity with the mediæval view of nature, and its semi-pagan offspring, the romantic view, he was brought, for the greater part of his life, to look upon the world of men and things either as the middle scene of a miracle play, with a heaven of rewarding happiness above and a purgatory of purifying pain below, or else as a garment concealing, while it revealed, spiritual forms of unfathomed mystery. During this time he could hear "the trailing garments of the night sweep through her marble halls," and see "the stars come out to listen to the music of the seas." Later on, as he approached his second youth (he was spared a second childhood), he tended to a more pagan view. About the time when he was writing *The Mask of Pandora*, he could see "in the sunset Jason's fleece of gold," and hear "the waves of the distracted sea pitiously calling and lamenting" his lost friend. But through all the periods of his life his view of the world was essentially religious and subjective, and, consequently, his manner of dealing with it hymnal or lyric. This fact, even more than his merits as an artist, serves to account for his immense popularity. Too well-informed, too appreciative, and too modest to deem himself the peer of the "grand old masters," or one of "those far stars that come in sight once in a century," he made it his aim to write something that should "make a purer faith and manhood shine in the untutored heart," and to do this in the way that should best reach that heart. This aim deterred him at once his choice of subjects and his mode of treating them.

The subjects of Longfellow's poetry are, for the most part, aspects of nature as influencing human feeling, either directly or through historical association, the tender or pathetic sides and incidents of life, or heroic deeds preserved in legend or history. He had a special fondness for records of human devotion and self-sacrifice, whether they were monkish legends, Indian tales, Norse *dræpas*, or bits of American history. His mode of treatment, as we have already said, is subjective and lyric. No matter what form his works

assume, whether the epic, as in "Evangeline," "The Courtship of Miles Standish," and "Hiawatha," the dramatic, as in "The Spanish Student," "The Golden Legend," and "The Mask of Pandora," or the didactic, as in "The Psalm of Life" and many of the minor poems; they are all subjective. This is not the highest praise that can be given to works of art; but it implies less dispraise in Longfellow's case than in almost any other, by reason of his noble subjectivity.

If we look in Longfellow's poetry for originality of thought, profound psychological analysis, or new insights into nature, we shall be disappointed. Though very far from being hampered by any dogmatic philosophical or religious system of the past, his mind, until near the end, found sufficient satisfaction in the Christian view of life to make it indifferent to the restless, inquiring spirit of the present, and disinclined to play with any more recent solution of life's problems. He had no sympathy with either scepticism or formal dogmatism, and no need to hazard rash guesses respecting man's destiny. He was willing to say—

"I do not know; nor will I vainly question  
Those pages of the mystic book which hold  
The story still unrolled.  
But without rash conjecture or suggestion  
Turn its last leaves in reverence and good heed,  
Until 'The End' I read."

He disliked the present psychological school of art, believing it to be essentially morbid and unhealthy. He had no sympathy with the tendency represented by George Eliot, or with any attempt to be analytic in art. He held art to be essentially synthetic, creative, and manifesting, not analytic, destructive, or questioning. Hence he never strove to draw from nature some new secret, or to show in her relations never discovered before. His aim was to impress upon her familiar facts and aspects the seal of his own gracious nature. And in this no one ever succeeded better. "The light of the life of him is on all past things." For this reason, while his poems never reveal to us a new meaning in nature or show us a new spring of hope in man, they make us love both better than we did before. Though he never raised the curtain that hides the stage upon which the physical and moral powers of nature rehearse the drama of human life, yet he opens our ears to the notes of the orchestra that sits before the stage and plays the overture; and, as we listen to these notes, there rise before us touching pictures of love, and faith, and devotion, until we find ourselves melted down and simplified into little children, whereof is the kingdom of heaven.

We have said that Longfellow's protracted residence in Europe in some degree unfitted him for expressing the new life of the American republic; and this is true. He was essentially a poet of the past, not, like Lowell, a grasper and moulder of the present, or like Whitman, a John the Baptist of the future. But, just as Dante summed up the ages of faith, and Shakespeare the ages of feudalism, so Longfellow has summed up the period of transition from these to the ages of truth and liberty—a period in which the killing letter of Christian womanliness and pagan manliness has slowly been yielding to their vivifying spirit, and preparing the way for that simple humanity of which he was the earnest and the type.

As a man, Longfellow was almost perfect, as much so as it is ever given to human nature to be. A man in intellect and courage, yet without conceit or bravado; a woman in sensibility and tenderness, yet without shrinking or weakness; a saint in purity of life and devotion of heart, yet without asceticism or religiosity; a knight-errant in hatred of wrong and contempt of baseness, yet without self-righteousness or cynicism; a prince in dignity and courtesy, yet without formality or condescension; a poet in thought and feeling, yet without jealousy or affectation; a scholar in tastes and habits, yet without aloofness or bookishness; a dutiful son, a loving husband, a judicious father, a trusty friend, a useful citizen, and an enthusiastic patriot, he united in his strong, transparent humanity almost every virtue under heaven. A thoroughly healthy, well-balanced, harmonious nature, accepting life as it came, with all its joys and sorrows, and living it beautifully and hopefully, without canker and without uncharity. No man ever lived more completely in the light than Henry Wadsworth Longfellow.

Perhaps the most remarkable traits in Longfellow's character were his accessibility and his charity. Though a great worker, he seemed always to have time for anything he was asked to do. He was never too busy to see a caller, to answer a letter, or to assist, by word or deed, any one that needed assistance. His courtesy to all visitors, even to strangers and children who called to look at him, or who, not venturing to call, hung about his garden-gate in order to catch a glimpse of him, was almost a marvel. He always took it for granted that they had come to see Washington's study, and, accordingly, took the greatest interest in showing them that. He never, as long as he could write, was known to refuse his autograph, and so far was he from trying to protect himself from intruders that he rarely drew the blinds of his study windows at night, though that study was on the ground floor and faced the street. His acts of charity, though performed in secret, were neither few nor small. Of him it may be said with perfect truth, "He went about doing good"; and not with his money merely, but also with his presence

and his encouragement. To how many sad hearts did he come like an angel, with the rich tones of his voice waking harmonies of hope, where before there had been despair and silence? How many young literary people, disappointed at the unsuccess of their first attempts, did he comfort and spur on to renewed and higher efforts! How careful he was to quench no smoking flax! How utterly free he was from jealousy or revengefulness! While poor, morbid Edgar Allan Poe was writing violent and scurrilous articles upon him, accusing him of plagiarism and other literary misdemeanours, he was delivering enthusiastic lectures to his classes on Poe's poetry. His charity was unbounded. Once when the present writer proposed to the president of the Harvard University Visiting Committee that Longfellow should be placed on that committee, the president replied: "What would be the use? Longfellow could never be brought to find fault with anybody or anything." And it was true. His whole life was bathed in that sympathy, that love which suffers long and envies not, which forgives unto seventy times seven times, and as many more if need be. Even in his last years, when loss of friends and continual physical pain made life somewhat "cold, and dark, and dreary" for him, he never complained, lamented, or blamed the arrangements of nature, and the only way in which it was possible to know that he suffered was through his ever increasing delight in the health and strength of younger men. His whole nature was summed up in the lines of his favourite poet:

"Luce intellettuale, piena d'amore,  
Amor di vero ben, pien di letizia,  
Letizia che trascende ogni dolore"

(T. DA)

LONGFORD, an inland county of Leinster, Ireland, is bounded on the N.W. by Leitrim, N.E. by Cavan, E. by Westmeath, S. by Westmeath and Meath, and W. by Lough Ree and Roscommon. With the exception of Carlow, Louth, and Dublin, it is the smallest county in Ireland, its greatest length being about 28 miles, its greatest breadth about 20, and the total area comprising 269,109 acres, or about 421 square miles.

The general level surface of the country is broken occasionally by low hills, which cover a considerable area at its northern angle. The principal rivers are the Camlin, which rises near Granard, and flows past Longford to the Shannon, and the Inny, which, entering the county from Westmeath, crosses its southern corner, and falls into Lough Ree. Lough Ree is partly included in Longford, and the other principal lakes are Lough Gownagh, Derrylough, Lough Drum, and Lough Bannow. The Royal canal intersects the county. The southern division of the county, bounded partly by the Camlin, belongs to the great limestone plain of Ireland, and the northern division is occupied chiefly by clay-slate and greywacke. In the west of the county there is an interpolation, between the two divisions, of yellow sandstone and conglomerate. Isolated hills of sandstone occur at Slievegauldry and at Ballymahon, on both sides of the Inny. Marble of fine quality has been raised near Ledwithstown. In the north indications of iron are abundant, and there are also some traces of lead.

*Agriculture.*—The climate is somewhat moist and cold, partly owing to the large extent of marsh and bog. The soil in the southern districts resting on the limestone is a deep loam well adapted for pasture, but in the north it is often so thin and poor as to be incapable of reclamation.

In 1881 there were 71,876 acres under tillage, 125,838 pasture, 3697 plantation, and 51,333 waste. The total number of holdings in 1880 was 8682, of which 685 were less than 1 acre. More than one-half of the total number were included in those between 5 and 15, and 15 and 30 acres in extent, which numbered respectively 2482 and 2658. The following table shows the areas under the principal crops in 1855 and in 1881:—

	Other Cereals	Potato	Turnips	C. Crops	Flax	Meado and Clover
1855	307	18,670	253	16	13,108	2,621
1881	307	18,670	253	16	13,108	2,621

The total number of horses in 1881 was 6856, of which 425 were used for agricultural purposes; of cattle 51,547, of which 16,217 were milch cows; of sheep, 24,140; of pigs, 17,900; and of poultry, 232,324. There were 3986 asses and 670 mules. According to the latest return, the land was divided among 436 proprietors possess-

ing 256,668 acres, with an annual rateable value of £151,739, the average rateable value per acre being 11s. 10d. The average size was 588 acres, and 14 per cent. possessed less than 1 acre. The largest owners were Colonel King Harman, 28,779 acres; earl of Granard, 14,978; Lord Annaly, 12,160; George Maconchy, 10,319.

*Manufactures.*—These are confined almost entirely to coarse woollen and linen cloth.

*Railways.*—One branch of the Midland Great Western Railway skirts the eastern boundary of the county, and another passes through its centre to Longford.

*Administration and Population.*—The county includes 6 baronies, with 26 parishes and 891 townlands. It is in the north-west circuit. Assizes are held at Longford, and quarter sessions at Ballymahon, Granard, and Longford. There is one poor law union wholly within the county, with portions of other two. It is in the Dublin military district and Birm subdistrict. There are barracks for infantry and cavalry at Longford. The county returns two members to parliament.

The only town of any importance is the county town, Longford. From 25,142 in 1760 the population of the county gradually increased till in 1841 it was 115,491, but since then it has diminished to 82,348 in 1851, 64,501 in 1871, and 61,099 in 1881, of whom 30,779 were males and 30,239 females. From 1st May 1851 to 31st December 1881 the number of emigrants was 40,726. For the ten years 1871–81 the marriage-rate per 100 of the population was 4, the birth-rate 24.3, and the death-rate 16. In 1881 23.1 per cent. of the population above five years of age were illiterate, the percentage in 1871 being 32. The Roman Catholics formed 91 per cent. of the population in 1881, and the Episcopalians 8.

*History and Antiquities.*—The early name of Longford was Annaly or Annaly, and it was a principality of the O'Farrells. Along with the province of Meath, in which it was then included, it was granted by Henry II. to Hugh de Lacy, who planted in it an English colony. On the division of Meath into two counties in 1543, Annaly was included in West Meath, but in the 11th of Elizabeth it was made shire ground under the name of Longford, and included in the province of Connaught, from which it was transferred to Leinster in the 27th of the same reign.

The principal antiquarian ruin is the Danish rath called the Mount of Granard, at the end of the main street of the town, and occupying a position 593 feet above sea-level. There are monastic remains at Ardagh, Longford, Moydow, Clone, Derg, Drumichel, and Killinmore, as well as on several of the islands of Lough Ree. The principal old castles are those of Rathelme near Lanesborough, and Ballymahon, Burnacor, and Castlecor on the Inny. The principal modern seats are those of Carrickglass on the Camlin, and Castle Forbes, the seat of the earl of Granard. Oliver Goldsmith was born at Pallas, a village near Ballymahon, in this county.

LONGFORD, the chief town of the above county, is situated on the river Camlin, and on a branch of the Midland Great Western Railway, 75 miles west-north-west of Dublin. The principal buildings are the parish church in the Grecian style, St Mell's Roman Catholic cathedral (one of the finest Roman Catholic churches in Ireland), the court-house, the market-house, and the county jail. Of the old castle and of the Dominican abbey there are slight remains. The town has a considerable trade in grain, butter, and bacon. There are corn-mills, a spool factory, and tanneries. The population in 1871 was 4375, and in 1881 it was 4380.

The ancient name of the town was Athlada, and it is said to occupy the site of a monastery founded by St. Blas, a disciple of St. Patrick. The town obtained a fair and market from James I., and a charter of incorporation from Charles II., as well as the right to return two members to parliament. It was disfranchised in the Union.

LONGINUS, a philosophical critic of great eminence, and one of the brightest spirits of antiquity, uniting Greek subtlety with Roman fervour, flourished in the 3d century, and is known to have perished under sentence of the emperor Aurelian in 273 A.D. He forms one of the last brilliant cluster of pagan literati; and Porphyry, round whom it centred, was the pupil of Longinus. As Porphyry is known to have been born in 233, it is probable that his preceptor, who could not have been less than twenty years his senior, may have been born about 210 A.D. The main authority for the facts of his life is a notice in Suidas, where we find it stated in a preface to a list of his writings that "Longinus Cassius, philosopher, preceptor of Porphyry the philosopher, a learned scholar and critic, lived in the time of the emperor Aurelian, and was cut off by him as

having conspired with Zenobia, the wife of Odenathus." From the same authority we learn that Phronto, the rhetorician of Emesa in Syria, was his uncle, and that Phrontonis, sister of Phronto, was mother to Longinus, who thus became heir to his uncle Phronto. As to his birthplace there is no tradition, but it is probable that he was a native of Syria, possibly of Emesa, to which his uncle belonged. He tells us, as we learn from fragments of his works, that he enjoyed great advantages in travel and education, that his parents, being rich, took him to travel and he saw much of the world, and that he studied at Athens under Phronto, at Alexandria under Ammonius Saccas and the pagan Origenes, and at Rome under Plotinus and Amelius. The Neo-Platonic philosophy was then in the ascendant, but Longinus did not embrace the new speculations which Plotinus was then developing, and continued a Platonist of the old type. Hence the sting of a sarcasm attributed to Plotinus—"Longinus may be a philologist, but he is no philosopher." Longinus does not appear to have reciprocated the sarcastic feeling, for we have still extant a fragment of a letter in which he asks Porphyry to come to Phœnicia and to bring with him the treatises of Plotinus, for, he observes, though he does not feel much attraction for the subjects, he yet likes the man. The reputation which Longinus acquired by his learning was immense; it was of him that Eunapius first used the expression that has since become proverbial "a living library"—in modern phrase, a walking encyclopædia.

The most conspicuous event of his life was also the most tragic in its consequences. He became secretary to Zenobia, the widowed queen of Palmyra, who acquired from him a knowledge of Greek, and made him her chief counsellor in state affairs. In this capacity he favoured the policy by which she aimed at independence of the Roman empire, encouraged, doubtless, to do so by the recent fate of Valerian, and by the feebleness of the tenure by which Rome held the Syrian provinces. Aurelian, however, crushed the pretension, and, while Zenobia lost her power and was led captive to Rome, Longinus paid the forfeit of his life. According to Zosimus, Zenobia sought to exculpate herself with Aurelian by laying the whole blame on her adviser. He died bravely, not seeking to escape his fate by suicide as a Stoic might have done, but following the example of Socrates and the precept of Plato, to whose philosophy he adhered.<sup>1</sup>

The remains of Longinus that have come down to us, unfortunately scanty, are partly fragments of letters and extracts from criticisms on points of diction; and they bear out the impression we derive from the historical notices of the man. He is vivid and yet minute, lively and penetrating, and his observations show taste, learning, and judgment. Among the most notable of the fragments we have a defence of the Platonic doctrine of the soul as a distinct essence from the body, which defines clearly his philosophical position.

It only remains to advert in a few words to the remarkable production called the *Treatise on the Sublime*, which has usually passed current as a work of Longinus. This remarkable work, which is among the most notable productions of ancient criticism, second only in importance to the *Poetics* of Aristotle, and superior to that work in luminous beauty and sense of form, cannot be with certainty ascribed to Longinus, although the internal evidence favours the usual ascription. Of the two most startling difficulties the first is the absence of any mention of a treatise *περί ὑψους* in the list by Suidas. The enumeration is, however, incomplete, and the phrase "many other works," with which it closes, may be held to cover much. A more formidable difficulty is the circumstance that in the most important

<sup>1</sup> It is probable that he owed part of his political fervour to the influence or inheritance of the name "Cassius," from whatever source this surname was derived. The associations of this name were distinctly anti-imperial and even regicidal, as seen in Caius Cassius and in Cassius Chærea.

manuscript (that in the Paris Library, No. 2036, of the 10th century) the heading is *Διονυσίου ἡ Λογγίνου*, giving thus an alternative author "Dionysius," and in the other important MS., the Laurentian at Florence, the title is *Ἀναγνώμης*, implying that the author was unknown. According to Vaucher (*Études*, p. 134) this title is not the original one, and there are traces of an earlier title *Λογγίνου*, which had formed the superscription. Full information as to the critical question will be found in the editions of A. E. Egger (*Longini quæ supersunt*, Paris, 1837), Vaucher's *Études Critiques sur le Traité du Sublime et sur les écrits de Longin*, Geneva, 1854, and Otto Jahn's *Διονυσίου ἡ Λογγίνου περὶ ὕψους ἢ Sublimitatē Libellus*, Bonn, 1867. Vaucher ascribes the treatise to Plutarch, but the evidence negatives that supposition, and, although there are difficulties in ascribing the work absolutely to Longinus, as Boileau and Gibbon and the critics of last century traditionally assumed, there is no other name than that of Longinus that presents so many concurring circumstances, to justify provisionally the current ascription. The fragments that remain of the undoubted works of Longinus are largely characterized by the same lively force and epigrammatic terseness which distinguish the treatise, "On the Sublime." The translations of this treatise into all the European tongues have been almost innumerable, including the famous one by Boileau, which rendered the work the favourite text-book of the belletristic critics in the last century. The most important English translations are by William Smith, 1739, frequently reproduced; Hathaway, 1834; Spurdens, 1836. (W. D. G.)

**LONG ISLAND**, an island with an area of 1682 square miles lying off the coast of the United States, between

40° 33' and 41° 10' N. lat., and forming part of the State of New York. While the length from east to west is about 120 miles, the width nowhere exceeds 24 miles, and in some places falls to 12 or 15. The western end is separated from the city and State of New York by the East River, which is nowhere more than three quarters of a mile in breadth, and has been spanned by a great suspension bridge; but between the main body of the island and the mainland (Connecticut, Rhode Island) lies Long Island Sound, widening out to a breadth of 20 miles. The sound, however, is comparatively shallow, the depth in the eastern and seaward portion being usually under 200 feet, while in the portion west of Connecticut river it is nowhere more than 170 feet, and in general only 75-100 feet. Geologically the island is very interesting, consisting, as it does for the most part, of an immense morainal deposit of glacial drift. A range of hills extends with some interruptions for about 60 miles in the line of its longer axis, varying in height from 150 to 384 feet above sea level. Fort Pond Hill for instance is 194 feet; Neapeague, 135; Amagansett, 161; Shinnecock, 140; Osborn's Hill, near Riverhead, 293; Ruland's, south of Coram, 310; West Hills (Jane's Hill), 354; Layton's Hill, 380; Westbury, 260; Hempstead

Map of Long Island.

Harbour Hill, 384; John M. Clarke's Hill, 326. From the foot of the hills southward stretches a vast nearly level plain, with an average height of 70 feet, and consisting of post-glacial stratified sand and gravel; and across this run a large number of shallow parallel watercourses, remarkable mainly for the regularity with which they present an elevated bank on the western side and a long declivity on the eastern. On the northern side of the range the surface is very uneven, some of the elevations exceeding 200 feet, and deep fiord valleys stretching down to the sound, and forming a series of excellent harbours. The glacial drift of Long Island is of immense depth, and contains a wonderful number of boulders. "At the eastern extremity," says Lyell on the authority of Mather, "they are of such kinds of granite, gneiss, mica, slate, greenstone, and syenite as may have come across the sound from parts of Rhode Island. Opposite the mouth of the Connecticut river they are of such varieties of gneiss and hornblende slate as correspond with the rocks of the region through which that river passes. Still further west they consist of red sandstone and conglomerate and the trap of that country, and lastly, adjoining the city of New York, we find serpentine, red sandstone, and various granitic and crystalline rocks

which have come from the district immediately to the north." One of the boulders near Manhasset measures 54 feet long and 40 feet wide, and rises 16 feet above the level of the soil. Of the numerous lakelets scattered throughout Long Island it is enough to mention Ronkonkoma, near Lakeland, the waters of which are said to decrease and increase in regular periods of four years. Much of the surface of the country is still covered with wood—oak, hickory, and chestnut growing freely on the unmodified drift, and pine forests extending for about fifty miles through the sandy plains. A good rich loam abounds in the northern districts, and the lighter soils of the south are easily rendered productive. Market gardening especially is carried on with success. The climate is comparatively mild, the mean annual temperature being 49° to 51°, the maximum for the year between 95° and 100°, and the minimum 4° to 8°. The average rainfall is about 42.1 inches. Towards its western end more especially, the northern coast of Long Island presents a number of important bays—Glen Cove, Oyster Bay, Huntington Bay, Smithtown Bay, &c.; the western extremity is deeply bifurcated by a very irregular inlet, broken up by various islands into Gardiner's Bay, Little Peconic, and Great

Peconic; and along a large part of the southern coast stretches a remarkable series of lagoons, formed by a line of dunes varying in breadth from  $\frac{1}{4}$  to 1 mile, and connected at various points with the ocean. These last—of which the most important is Great South Bay, 40 miles long by about 5 or 6 miles wide—are of great service to the island, and an Act has been passed to increase their utility by connecting them by canals. Coney Island and Rockaway Beach, the most frequented of the many seaside resorts in the Island, lie near the south-western extremity. As regards both birds and fishes, Long Island seems a kind of meeting place between the arctic and the equatorial species. In winter, for instance, it is visited by the eider-duck, the little white goose, the great cormorant, and the auk, in summer by the turkey buzzard, the swallow-tailed kite, and the fork-tailed flycatcher. A few deer are still to be found; and various tracts of country and islands in the great bays are stocked with game and fish by sportsmen's clubs. The east portion of the island is one of the chief seats of the menhaden fisheries, and the oyster beds of both the north and the south coast are of great value. Those of the Great South Bay (furnishing, amongst others, the famous "blue points") alone give employment in the season to 1500 fishermen. (See E. Ingersoll, "The Oyster Industry," in the *Tenth Census* publications of the United States, 1881.)

Administratively Long Island consists of King's County (72 square miles), Queen's County (410), and Suffolk (1200), which in 1880 had the following population:—

	Total.	Male.	Female.	Native.	Foreign.	White.	Coloured.
King's ... ..	599,549	289,289	310,260	411,295	188,254	590,278	9,271
Queen's .....	90,547	45,760	44,787	64,556	25,991	86,707	3,840
Suffolk .....	53,926	26,759	27,167	48,319	5,607	51,473	2,453

Of the thirteen or fourteen Indian tribes living in the island at the time of its discovery, the only remnants are about fifty Shinnecocks and Montauks.

Besides Brooklyn, which had 566,689 inhabitants, King's County contained Flatbush town, 7634; Flatlands town, 3127; Gravesend town (including Coney Island village), 3676; New Lots town, 13,681; and New Utrecht town, 4742. In Queen's county are Flushing town, 15,919; Hempstead town (including East Rockaway, Garden City, and sixteen other villages), 18,160; Jamaica town, 10,989; Long Island City, 17,129; Newtown town, 9798; North Hempstead town, 7562; and Oyster Bay town, 11,923. In Suffolk there are no cities, and none of the villages have 500 inhabitants. The "towns" are Babylon, Brookhaven, East Hampton, Huntington, Islip, Riverhead, Shelter Island, Smithtown, Southampton, and Southold. Garden City was built by A. T. Stewart as a model suburban settlement, and contains a fine cathedral. Hicksville is associated with the memory of Elias Hicks the Quaker missionary. Sag Harbour was formerly a great whaling station, and still maintains a good coasting trade. Five miles from Flushing is Creedmore rifle range, the finest in the United States. On Gardiner's Island the pirate Kidd concealed the treasures partly recovered by the governor of Massachusetts in 1699.

Long Island was so called by its Dutch discoverers in 1609, and the name Nassau, bestowed in 1693 by the colonial legislature, never found popular acceptance. Breucklen (Brooklyn), Amersfoort (Flatlands), Vlissingen (Flushing), Rusdorf (Jamaica), and New Utrecht were founded by the Dutch between 1630 and 1654; and between 1646 and 1665 the English from the New England colonies established Southold, Southampton, Easthampton, Hempstead, Huntington, Oyster Bay, Smithtown, Islip, &c. Though the charter granted by James I. in 1629 expressly excluded territory actually possessed or inhabited by any other Christian prince or state, the grantees in 1635 conveyed to the earl of Stirling among other lands the island of Matinecock or Long Island. A treaty concluded between Dutch and English at Hartford (Connecticut) in 1650 surrendered to England all the land south of Oyster Bay; but, though it was ratified by the states-general of Holland in 1656, no action was taken by the English Government. Long Island was included in the territory assigned to the duke of York in 1663-64, and in 1634 an English squadron conquered the Dutch at time of peace, and set up a government in the duke's name. When the Dutch governor, who had recovered New York in 1673, issued a proclamation requiring the submission of the Long Island towns, they all obeyed except the three most eastern; but the treaty of Westminster in 1674 left Long Island to the English, and it became a regular colony of the crown. In the beginning of the

war of American independence, Long Island naturally played a prominent part. The efforts made by Washington to defend it were frustrated by the British under Cornwallis in 1776, and it remained in their hands till the close of the contest.

LONG ISLAND CITY, a city of the United States, the capital of Queen's County, New York, situated on the west coast of Long Island, and separated from New York by the East River and from Brooklyn by the Newtown Creek. The area, which includes what were the post villages of Astoria, Newtown, and Ravenswood, measures 3 miles from east to west and 5 miles from north to south, and the general plan of the place is constructed on a spacious scale. The river frontage extends to about 10 miles. Hunter's Point, as the south-west portion is called, contains the terminal depôts of several railway lines, extensive warehouses for the storage of petroleum, and a variety of industrial establishments—such as granite-works, chemical works, engine-works. In the Astoria district there are factories for pianos, carriages, and carpets. Long Island City dates from 1870; in 1874 its population was about 16,000, and in 1880 17,117.

LONGITUDE. See GEOGRAPHY (MATHEMATICAL) and TIME.

LONGOMONTANUS, or LONGBERG, CHRISTIAN (1562-1647), a Danish astronomer, was born at Longberg, a village of Jutland, in Denmark, on the 4th of October 1562. Having, when only eight years old, the misfortune to lose his father, who was only a poor labourer, he was taken charge of by a maternal uncle, through whose influence he received lessons from the clergyman of the place. Although, owing to the poverty of his parents, the instruction which he had received up to this time had been of the most elementary kind, his aptitude for learning was so great that, under the tuition which he now received, he made rapid progress in his studies, especially in the mathematical sciences, for which he acquired an intense liking. His mother, however, was unable to pay any longer for his education, and he was reluctantly compelled to return home to work in the fields. By improving every opportunity which his laborious life now permitted, he was still enabled to pursue, to some extent, his favourite studies. This state of matters continued for some time; but his intense thirst for knowledge, and the uncalled-for jealousy of his friends, led him in 1577 to steal away from home, to try his fortune in the world. Accordingly, at the age of fifteen, he went to Wiborg, a town about 12 miles distant from his native village. There he spent eleven years, dividing his time between attending the lectures of the professors in the college of that town, and working in the fields. By this means he was able not only to earn a sufficient livelihood, but also to defray the expenses of his education; and his close application to study soon enabled him to acquire considerable knowledge of literature and of the sciences. In 1588, at the age of twenty-six, he removed to Copenhagen, where his great abilities speedily secured for him the esteem and admiration of the professors in the university of that town. By this means he was brought under the notice of the eminent astronomer Tycho Brahe, who received him very kindly, and ultimately appointed him his assistant. He remained with Tycho Brahe for eight years in the island of Høene, and during that time rendered him such valuable services in his astronomical observations and calculations that, when Tycho Brahe settled in Germany, he invited Longomontanus to accompany him. This offer he accepted; but having shortly afterwards expressed to Tycho Brahe his desire to return to his native country, the latter at once furnished him, not only with excellent testimonials, but also with money for his journey. On his return to Denmark he made a long detour in order to visit the places whence Copernicus

had made his celebrated astronomical observations. On his arrival at Copenhagen, he found a patron in the person of Christian Friis, chancellor of Denmark, who gave him employment in his household. He continued in this situation till 1603, when he received the appointment of rector of the college of Wiborg. Two years later (1605) he was elected to the chair of mathematics in the university of Copenhagen. This appointment he held till his death, on the 8th of October 1647. Longomontanus, although one of the best astronomers of his age, inherited some of its worst prejudices. A firm believer in astrology, he held, among other things, that comets were messengers of evil. He also imagined that he had squared the circle. He found that the circle whose diameter is 43 has for its circumference the square root of 18252, which gives 3.14185 . . . . . for the value of  $\pi$ . Pell and others endeavoured to prove that he was mistaken, but they failed to convince him of his error. He refers to his imagined discovery in almost all his published works, and defends his position with great zeal.

The following is a list of his more important works in mathematics and astronomy, with the dates of their first publication:—*Systematis Mathematici*, &c., 1611; *Cyclometria e Lunulis reciproce demonstrata*, &c., 1612; *Disputatio de Eclipsibus*, 1616; *Astronomia Danica*, &c., 1622; *Disputationes quatuor Astrologice*, 1622; *Pentus Problematum Philosophicæ*, 1623; *De Chronologia Historico, seu de Tempore Disputationes tres*, 1627; *Geometricæ quæstiones XIII. de Cyclometria rationali et vera*, 1631; *Inventio Quadraturæ Circuli*, 1634; *Disputatio de Mathematicis Indolæ*, 1636; *Coronis Problematica ex Mysteriis trium Numerorum*, 1637; *Problematæ duo Geometricæ*, 1638; *Problema contra Paulum Guldinum de Circuli Mensura*, 1638; *Introductio in Theatrum Astronomicum*, 1639; *Rotundi in Plano*, &c., 1644; *Admiranda Operatio trium Numerorum 6, 7, 8, &c.*, 1645; *Caput tertium Libri primi de absoluta Mensura Rotundi plani*, &c., 1646.

LONGUEVILLE, ANNE GENEVIEVE, DUCHESSE DE (1619–1679), who played the greatest part in the troubles of the Fronde, and whose name has come down to posterity as the brilliant intriguer in politics in her early and the pious protectress of the nuns of Port Royal in her later years, was the only daughter of Henri de Bourbon, Prince de Condé, and his wife Charlotte Marguerite de Montmorency, and the only sister of Louis, the great Condé. She was born on August 28, 1619, in the prison of Vincennes, into which her father had been thrown for opposition to Marshal D'Ancre, the favourite of Marie de' Medici, who was then regent in the minority of Louis XIII. She was educated in the convent of the Carmelites in the Rue St Jacques at Paris, which had been recently established under the influence of St Teresa's reforms by nuns of the strictest piety, whose teaching she never entirely forgot. Her early years were clouded by the execution of the young and brilliant Duc de Montmorency, her mother's only brother, for intriguing against the great Richelieu in 1631, and that of her mother's cousin the Comte de Montmorency Boutteville for duelling in 1635; but, in spite of their sorrow, her parents made their peace with Richelieu, and when she was introduced into society in 1635 she found plenty of court gaiety to enjoy. She soon became one of the bright particular stars of the Hôtel Rambouillet, where all that was learned, witty, and gay in France used to assemble, and which had not yet degenerated into the meeting place of those *précieuses* whom Molière was to laugh out of existence. It was first proposed to marry her to the young Prince de Joinville, and thus unite the Guises and Condés, but he died in 1639, and her parents could only find for her husband the Duc de Longueville, a prince of the blood indeed, and governor of Normandy, but a widower, and twice her age. The marriage could not be a happy one, but the young duchess long remained faithful to him, and bore him four children. After Richelieu's death her father became chief of the council of regency during the minority of Louis XIV., her brother

Louis won the great victory of Rocroy in 1643 (see CONDÉ), and the duchess became of political importance. In 1617 she accompanied her husband to Münster, where he was sent by Mazarin as chief envoy, and where she charmed the German diplomatists who were making the treaty of Westphalia, and was addressed as the "goddess of peace and concord." On her return she fell in love with the Duc de la Rochefoucauld, the author of the *Maxims*, who made use of her love to obtain influence over her brother, and thus win titles and honours for himself. She was the guiding spirit of the first Fronde, when she brought over Armand, Prince de Conti, her second brother, and her husband to the malcontents, but she failed to attract Condé himself, whose loyalty to the court overthrew the first Fronde. However, La Rochefoucauld won the titles he desired. The second Fronde was again her work, owing to her lover's disgust at losing his new honours, and in it she played the most prominent part in attracting to the rebels first Condé and later Turenne (see CONDÉ). It is not necessary to give the whole history of the wars of the Fronde, which is detailed elsewhere, but it must be noticed that the duchess herself only mingled in politics to please her lover, and gain his ends. In the last year of the war she was accompanied into Guienne by the young and handsome Duc de Nemours, her intimacy with whom gave La Rochefoucauld an excuse for abandoning her, and who himself immediately returned to his old mistress the Duchesse de Chevreuse. Thus abandoned, and in disgrace at court, the duchess betook herself to religion. She accompanied her husband to his government at Reuen, and devoted herself to good works. She took for her director M. Singlin, so famous in the history of Port Royal, and from that time began her new religious life. Till 1663 she chiefly lived in Normandy, when her husband died, and she came to Paris. There she became more and more Jansenist in opinion, and her piety and the remembrance of her influence during the disastrous days of the Fronde, and above all the tender love her brother, the great Condé, bore her, made her a conspicuous figure. The king pardoned her, and in every way showed the respect he had for her. She became the great protectress of the Jansenists; it was in her house that Arnauld, Nicole, and De Lane were protected; and to her influence must be in great part attributed the release of De Sacy from the Bastille, the introduction of Pomponne into the ministry and of Arnauld to the king. Her famous letters to the pope are part of the history of PORT ROYAL (*q.v.*), and as long as she lived the nuns of Port Royal des Champs were left in safety. Through the latter years of her life she had, despite the honour in which she was held, much to bear. Her elder son resigned his title and estates, and became a Jesuit under the name of the Abbé d'Orléans, while the younger, after leading a very debauched life, was killed, bravely leading the attack in the passage of the Rhine in 1673. As her health failed she devoted herself more and more to religion, and hardly ever left the convent of the Carmelites in which she had been educated. On her death in 1679 she was buried with great splendour by her brother Condé, and her heart, as she had directed, was sent to the nuns of that Port Royal des Champs which she had so greatly protected and defended. Her life is noteworthy, both from the harm she did in the turbulent days of the Fronde, though she acted, hardly knowing what she did, from love rather than from selfish ambition, and also from the greatness of her penitence, when her protection of Port Royal more than redeemed her fame, and gave her a title to the grateful remembrance of all who reverence true piety and learning more than the artificial glitter of the reign of the "grand monarque."

The chief authority for Madame de Longueville's life is a little book in two volumes by Villedore the Jansenist, published in 1738.

Cousin has devoted four volumes to her, which, though immensely diffuse, give a vivid picture of her time. Her connexion with Port Royal should be studied in Arnauld's *Mémoires*, and in the different histories of that institution.

LONGUS, the Greek romancer. Nothing is known of the life of the author of *Daphnis and Chloe*, and it is only inferred from some apparent imitations of the *Æthiopica* of Heliodorus that he wrote after the time of Theodosius. He may therefore be placed in the 5th century. His position in literature is interesting and not unimportant: he represents the romantic spirit of expiring classicism, the yearning of a highly artificial society for primitive simplicity, and the endeavour to create a corresponding ideal. The little idyl in the seventh oration of Dion Chrysostom is a beautiful example of this tendency three centuries before Longus, and the letters of Synesius, nearly in his own day, attest a genuine feeling for nature and a country life. In its literary aspect, nevertheless, this movement has little in common with the return to pure nature which inspired a Wordsworth, or the realism of George Sand's delineations of the peasantry of Berri. Longus's style is rhetorical, and his shepherds and shepherdesses are wholly conventional. It is no small credit to him to have achieved so purely ideal a delineation with so little apparent affectation, and without any of the tediousness of almost all modern pastoral writers. If unable to blend the reality and ideality of the pastoral life as Shakespeare has done in *As You Like It* and *The Winter's Tale*, he has nevertheless imparted real human interest to a purely fanciful picture, and shows no little knowledge of human nature in his delineation of the growth of a passionate attachment between two innocent children. Daphnis and Chloe were probably the prototypes of Paul and Virginia; and, notwithstanding the naivete of some details, the Greek has a decided advantage over the Frenchman in the simplicity and sincerity which constitute the true modesty of nature. As an analysis of feeling, *Daphnis and Chloe* makes nearer approach to the modern novel than its chief rival among Greek erotic romances, the *Æthiopica* of Heliodorus, where the attraction mainly consists in the ingenious succession of incidents.

Longus has found an incomparable translator in Amyot, bishop of Auxerre, whose French version, as revised by Paul Louis Courier, is better known than the original. It appeared in 1559, fifty-nine years before the publication of the Greek text at Florence by Alamanni. The chief subsequent editions are those by

Jungermann (Hanau, 1603), Villoison (Paris, 1778, which first gave a standard text), Courier (Rome, 1810, the first entirely complete edition), Seiler (Leipsic, 1835), and Piccolos (Paris, 1866), pronounced by M. Pons the *ac plus ultra* of accuracy. Pons's account of the literature and bibliography of the subject, appended to his edition of Courier's version (1878), is very careful and complete. There are English translations by Thornley, Craggs, and Le Grice, the last with omissions. The illustrated editions, generally of Amyot's version, are very numerous, and some are very beautiful. Prudhon's designs are especially celebrated.

LONS-LE-SAULNIER, capital of the department of Jura, Frante, is situated at a distance of 275 miles by rail from Paris, on the Vallière, a small tributary of the Saône, about 820 feet above the sea-level, at the point where the Besançon, Lyons, and Châlon-sur-Saône railways converge. It is pleasantly surrounded by vine-clad hills from 300 to 500 feet in height, consisting of lower spurs of the Jura chain. It owes its name to its salt-pits, which have been used from a very remote period; the large quantities of ashes derived from the wood burnt in the process of evaporation are extensively utilized in agriculture. Since 1839 there has been an establishment for the use of the mineral waters. The principal industry of the place is the manufacture of sparkling wines, the Étoile growth being the best for this purpose. There is also a foundry, in addition to printing establishments, tanneries, distilleries, brush factories, and manufactures of coverlets and carpets. About a mile to the west of the town are the salt-mines of Montmorot, employing one hundred and fifty workmen; the bed of rock salt, which lies at a depth of 400 feet, and is nearly 100 feet thick, yields about 9500 tons of pure salt yearly, 885 tons of sulphate of soda, and 300 tons of chloride of potassium. Lons-le-Saulnier possesses no buildings of special interest; one of the public squares contains a statue of Lecourbe, and there is a museum containing Gallo-Roman antiquities and various works of art. The library, which like the museum is in the town-hall, has 20,000 volumes. The population in 1876 was 11,371.

Lons-le-Saulnier, originally a Gallic town, was fortified by the Romans, destroyed by the barbarians, and, afterwards rebuilt and extended, belonged for a long time during the mediæval period to the powerful house of Châlon, a younger branch of that of Burgundy. It was burned in 1364 by the English, and again in 1637, when it was seized by the duke of Longueville for Louis XIII. It became definitively French in 1674. It was there that the meeting between Ney and Napoleon took place, on the return of the latter from Elba, on March 31, 1815. Rouget de l'Isle, the author of the Marseillaise Hymn, was born at Montaigu near this town.

## The Century Dictionary

THE CENTURY DICTIONARY, originally published by The Century Company of New York, and now issued by THE TIMES, consists of eight volumes, 12 inches in height, 9 inches in depth, and 2 inches in breadth. It enumerates about 225,000 words, over 500,000 distinct definitions, and over 300,000 quotations. More than 7,000 illustrations appear on the 7,000 large quarto pages. The editor, Professor William Dwight Whitney, was assisted by a staff of 500 specialists in various fields of knowledge. The *London Daily Telegraph* describes THE CENTURY DICTIONARY as "one of the most notable monuments of philological industry of the age"; the *Standard* speaks of it as "a comprehensive dictionary of the English language adapted to the requirements of every form of literary expression"; the *Spectator* says that it is "more complete and full than anything ever before attempted"; the *Athenæum* describes it as "far and away the largest and best general and Encyclopædic Dictionary of the English language," and says that "the exquisite taste and delicacy of the illustrations are a very important feature of the work"; the *Birmingham Daily Post* describes it as "a stupendous magazine of information on all matters that can engage the human intellect"; the *Graphic* speaks of it as "a magnificent book"; the *Illustrated London News* characterizes it as a "work of genius"; the *Liverpool Post* says that it is "a standard reference book for the student, the artist, the litterateur, the man of business, and the man of science, and for all who wish to have at hand a convenient book of universal information"; the *Scotsman* says that "it will be welcome wherever the English language is read, written, or spoken"; the *Bradford Observer* speaks of it as "by far the most copious dictionary of the English language in existence"; the *Sheffield Independent* says that it is "an adornment to any library"; the *Spectator* says that "it may be safely recommended to buyers as far and away the best book of its class in the market."

A pamphlet of specimen pages, together with detailed information as to the terms of sale, may be had post free upon application to the Manager of THE TIMES.

## The Encyclopædia Britannica

(THE TIMES REPRINT OF THE NINTH EDITION.)

THE TIMES Reprint of the ENCYCLOPÆDIA BRITANNICA is a reproduction of the Ninth Edition of that standard library of reference, without abridgment or alteration. THE ENCYCLOPÆDIA BRITANNICA consists of twenty-five volumes each about 11½ inches in height, 8½ inches in depth, and 2½ inches in breadth. There are 21,164 pages of text, containing nearly 30,000,000 words. The sixteen thousand articles are illustrated by 343 full-page plates, some 670 maps, and plans occupying less than a page each, and 7,456 engravings. Among the 1,100 contributors appear the names of the most distinguished men and women of our time.

THE TIMES Reprint of the ENCYCLOPÆDIA BRITANNICA is supplied at a price much lower than that at which Messrs. A. & C. Black, the publishers of the ENCYCLOPÆDIA BRITANNICA, had sold the work. More than 15,000 copies of the Reprint were sold between March 23rd, 1888, and March 23rd, 1891, and the fact that the volumes were printed in such large quantities enabled THE TIMES to effect a radical reduction in the cost of manufacture. A further facility is afforded to purchasers by the novel system of monthly payments, in accordance with which the purchaser receives the 25 volumes upon the payment of only one guinea.

A pamphlet, containing specimen pages and extracts from the work, together with full information as to the price of the work and the novel plan of monthly payments, may be obtained, post free, upon application to the Manager of THE TIMES.

### The Times Atlas

118 pp. WITH 175 MAPS. INDEX, 130,000 PLACES.

Cloth, 22s. 6d. Cloth, Gilt Edges, 23s. Half Morocco, Gilt Edges, 26s.

For transmission abroad the postal charges must be added to these prices. These range from 2s. 2d. to 10s.

THE TIMES ATLAS is an Atlas of General Geography, containing 118 pp. of beautifully coloured maps, an Index to 130,000 names, a Title-page, and Contents. In all copies of the ATLAS the maps are mounted upon linen guard so as to obtain a perfectly flat opening.

### The Times Gazetteer

In Cloth Binding, 17s. 6d. In Half Morocco, 24s. In Full Morocco,

THE TIMES GAZETTEER.—In virtue of an arrangement entered into with Messrs. Longmans & Co., the work hitherto known as Longmans' Gazetteer will hereafter be known as THE TIMES GAZETTEER.

Published in 1895, this work is in every respect a worthy companion to THE TIMES ATLAS. It consists of 1,788 pp., bound to 10½ in. by 7½ in. The type is sharply defined, and the disposition of the page is such as to give the greatest facility of reference at the cost of the least fatigue to the eye. In the more important matter of its accuracy and its completeness, THE TIMES GAZETTEER is a fitting shelf mate for THE TIMES ATLAS.

### The Mail

Every MONDAY, WEDNESDAY, and FRIDAY, 2d.

To any country abroad, 9s. 9d. per Quarter, post free.

THE MAIL is a reproduction of the principal matter of *The Times* for two days, printed in the same form as *The Times*, and on similar, but lighter, paper. It is published on the afternoons of every MONDAY, WEDNESDAY, and FRIDAY, and contains the latest intelligence up to 1 P.M. of those days.

It is *The Times* adapted especially for foreign subscribers who are unwilling to have six papers a week. It contains foreign and City intelligence, and the more important leading articles, local intelligence, and correspondence of *The Times*.

### The Times Weekly Edition

Every FRIDAY, 1d.

To any country abroad, 3s. 3d. per Quarter, post free.

Contains a careful epitome of the events of interest during the week together with the most important LEADERS and SPECIAL ARTICLES from *The Times* in extenso.

PARLIAMENT AND POLITICS.  
COLONIAL AND FOREIGN NEWS.  
NAVAL AND MILITARY MATTERS.  
TRADE, MONEY, AND STOCKS.  
ECCLESIASTICAL AND SOCIAL NOTES.  
REVIEWS OF BOOKS.

LAW AND POLICE.  
HOME AND DOMESTIC EVENTS.  
CORRESPONDENCE.  
CHESS, BY SPECIAL EXPERT.  
NEWS INTERESTING TO EVERY CLASS OF READERS.

AND A SERIAL STORY BY A POPULAR AND WELL-KNOWN AUTHOR.

### Literature

A Journal of International Literature.

Every SATURDAY, 6d.

To any country abroad, 7s. 7d. per Quarter, post free.

LITERATURE is a weekly paper published every SATURDAY and is the recognised organ of all Literary Classes. Authors, Publishers, and Readers. It gives attention to every movement in the Literary World or relating to Literature in the most extended sense of the word, to the Literature of this country of the English language, and the Literature of all countries.

MR. HENRY JAMES.	MISS FIONA MACLEOD.	DEAN STUBBS.
RUDYARD KIPLING.	MR. PERCY FITZGERALD.	PROFESSOR MAHAFFY.

### "Issues"

VOL. XVI., JULY DECEMBER, 1898, NOW READY.

4to., Half Morocco, price 10s. 6d.

A Half-Yearly Reprint of the Prospectuses of Public Companies, &c., advertised in *The Times*, together with the Results of Tenders, and a Statistical Index of Issues offered for Subscription.

### The Times Law Reports

Annual Subscription, £1 5s., post free. Single Numbers, 6d. each.

A Weekly Reproduction, in convenient form, of all Cases appearing in *The Times* of permanent interest to the Legal Profession, Bankers, Merchants, and the Public generally. Edited by the Hon. ARTHUR RUSSELL, of the Inner Temple, Barrister-at-Law. The Reports for the Weekly Number are revised, and appear with head notes, table of cases, and digest.

### Eleven Years' Digest of

The Times Law Reports, 1884 to 1895

Price 50s.

Specially compiled and edited. With Index of Cases.

### Reports of Commercial Cases

Price 2s. 6d. each.

Reported by R. H. BALLOCH and F. O. ROBINSON, Barristers-at-Law. Consisting of about 50 pp., published at short intervals.

PART II, VOL. IV., DECEMBER, 1898—JANUARY, 1899, NOW READY.

Bound Volumes are also issued. The FIRST VOLUME, including Reports from March to August, 1895, and for the judicial year 1895-1896, in half-calf, 25s., and VOLS. II. and III., half-calf, 20s. each.
